

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. THE NEW AMERICAN CYCLOPÆDIA.

EDWARD (THE ELDER)

EDWARD I., surnamed the Elder, son and successor of Alfred, king of the West Saxons, ascended the throne in 901, died in 925. His claim to the throne, though recognized by the witenagemote, was disputed by his cousin Ethelwald, who gained the support of the Northumbrian and East Anglian Danes. The rebels marched through the counties of Gloucester, Oxford, and Wilts, and Edward, unable directly to oppose them, retaliated their ravages in the country of the East Angles. He thought proper to withdraw his army, loaded with booty, before the approach of the rebels, but the venturous Kentish men, greedy of more spoil, stayed behind in defiance of orders. They were assaulted by the East Angles, and resisted so valiantly that though obliged at last to retreat, it was not till after they had slain a great number of the bravest of the enemy, and had terminated the rebellion by causing the death of Ethelwald himself. The reign of Edward, as of many of his predecessors and successors, was occupied with subduing the turbulent Danes, who abounded and were constantly reënforced in the provinces of East Anglia and Northumbria. In this task he was assisted by his sister Ethelfleda, who governed Mercia. He protected his territories by fortresses which gradually became centres of trade and population. He gained two signal victories at Tomsford and Maldon, and subjected all the tribes from Northumbria to the channel to his immediate control. He was twice married, and left a numerous family, and 8 of his sons, Athelstan, Edmund, and Edred, successively occupied the throne.

EDWARD II., surnamed the Martyr, king of the Anglo-Saxons, son and successor of Edgar, born in 962, ascended the throne in 975, and was murdered in 978. The intrigues of his stepmother Elfrida raised a faction in favor of her own son Ethelred, who was but 7 years of age. Ecclesiastical parties took opposite sides, the married clergy who had been ejected in the preceding reign regarding Elfrida as their patroness and supporting the pretensions of Ethelred, and the monastic followers of St. Dunstan maintaining the superior claim of Edward. A civil war had already begun, when at a general meeting of the witenagemote Edward was after much

EDWARD (THE CONFESSOR)

opposition formally accepted as king. The strife among the clergy, however, still divided the kingdom, and the party opposed to St. Dunstan plotted the murder of the young monarch. He was stabbed in the back at Corfe castle, the residence of his stepmother, as he was drinking a cup of mead on horseback, and sinking from his seat he was dragged away by the stirrup by his frightened horse.

EDWARD III., surnamed the Confessor, king of the Anglo-Saxons, son of King Ethelred II., successor to Hardicanute, born in Islip, Oxfordshire, in 1004, ascended the throne in 1042, died Jan. 5, 1066. His mother was a Norman princess, Emma, and during the Danish domination which had succeeded the death of Edmund Ironside, he dwelt in exile in Normandy. When the news of the death of Canute in 1085 reached him, he determined to assert his pretensions to the crown, crossed the channel with a fleet of 40 ships, and landed at Southampton. He found himself opposed by his mother, who had become a second time queen of England by marriage with the Danish monarch, and was now regent of the kingdom. Menaced with destruction by a constantly increasing force, he hastily effected his retreat. With his brother Alfred he received a perfidious invitation from King Harold to cross the sea in 1037. Alfred was murdered at Guildford, and Edward, apprised of the fate which was awaiting him, escaped into Flanders. After the accession of his half brother Hardicanute, Edward was received with honor into England, presented with a princely establishment, and was at court when the king suddenly died in 1042. The Danish heir Sweyn was then absent from the kingdom; the rightful heirs of the Saxon line, the sons of Edmund Ironside, were in exile in Hungary; the Anglo-Saxons were determined to throw off the Danish yoke; the Danes were divided and dispirited; Edward was the nearest to the throne of any one present, and after a short period of hesitation and commotion he was recognized as king in a general council at Gillingham. His reign was the period when the mutual aversion of the two fierce Teutonic peoples, whose struggles for dominion had vexed the country during 6 generations, began to subside, when intermarriages

and a blending of language and customs nearly effaced the distinction between the two races, and when the Normans began to exercise a potent influence in the country, both nations of which they were soon to prostrate. The first royal act of Edward was to strip his mother, whose resistance had defeated his first attempt to obtain the throne, of her immense treasures, and to confine her for life in a monastery at Winchester. The government was at this time in the hands of 8 powerful noblemen: Earl Godwin, who ruled all the southern provinces; Earl Leofric, who governed Leicester and the northern counties of Mercia; and Earl Siward, whose sway extended from the Humber to the confines of Scotland. Edward sought the protection of Earl Godwin by marrying his daughter Editha, a lady praised by the chroniclers for her learning, piety, and benevolence; yet the motive which prompted Edward to marry her was merely political, and the alliance proved therefore a source of enmity instead of friendship between the king and his father-in-law. Edward was partial both to Norman manners and people; many foreign churchmen and dignitaries had followed him to England, where they had acquired influence in the government. A popular jealousy was already felt against them, when in 1050 Eustace, count of Boulogne, with his train, visiting England, quarrelled with the burghers of Dover, and in the tumult several persons were slain. The affray was reported to the king at Gloucester, by the discomfited Eustace, and Edward gave orders to Godwin, in whose government Dover lay, to chastise the insolence of the men of that city. The earl refused to obey; a rupture was therefore unavoidable, and 3 armies under the command of Godwin and his 2 sons immediately marched against the king in Gloucestershire. Edward summoned to his aid Leofric and Siward, and was quickly in a condition to intimidate his opponents, when it was agreed to refer the dispute to the decision of the witenagemote. Godwin, however, fled with his wife and sons to Flanders; their estates were then confiscated, Queen Editha was confined in a monastery, and the greatness of this family seemed completely destroyed. Tranquillity was hardly restored when William, duke of Normandy, the future conqueror, reached the coast of England to render assistance to his royal kinsman. He was received in a manner worthy of his great reputation, visited several of the royal villas, and was dismissed with magnificent presents. Godwin, however, having gradually collected a fleet, suddenly appeared in 1052 on the southern coast of England, swept away the ships from the different harbors, entered the Thames, menaced London, and extorted from the king the restoration of himself and his son Harold to their earldoms and the banishment of the foreigners; and the primate and the numerous other Norman functionaries fled for their lives. Godwin did not long survive this triumph, and left his possessions to his son Harold, his equal in ambition and his superior in address.

At this period occurred the events which form the groundwork of Shakespeare's tragedy of "Macbeth." In 1039, Macbeth, a turbulent nobleman, murdered Duncan, king of Scotland, chased Malcolm, his son and heir, into England, and usurped the crown. The exiled prince received from Edward permission to vindicate his rights with an English army, but for 15 years the power of the murderer defeated every attempt. At length in 1054 Malcolm was successfully supported by Macduff, the thane of Fife, and by Siward, earl of Northumberland. The fall of Macbeth cost the death of the son of Siward; the Northumbrian earl died soon after, when Harold obtained that earldom, in opposition to the rights of an infant heir, for his own brother Tosti. Thus the support which Edward gave to Malcolm resulted in adding largely to the power of his own most ambitious and dangerous subject. To oppose Harold's further progress, the king invested Algar, the son of Leofric, with the government of East Anglia, but the intrigues of Algar quickly led to his expulsion from his new possession. He, however, soon returned into Herefordshire with an army of Welsh and Norwegian auxiliaries, was opposed by the inconstant English monarch, but was able to maintain the cause of the king in spite of the king himself, and returning again, forced Harold to a compromise and was reinstated in East Anglia. He was again expelled and again restored, and at his death in 1058 Harold was left without a rival, the most powerful subject in England. Edward the Outlaw, the Saxon heir to the throne, after a life of exile, died within a few days of his arrival in England, and there now stood between Harold and the crown only the young and feeble Edgar. The infirm old king, inveterate in his animosity to the family of Earl Godwin, turned his eyes toward his kinsman across the channel, William of Normandy, as a person whose capacity and power would render him the most formidable rival to Harold. Harold, being thrown in a tempest upon the coast of Normandy, was obliged while thus in the power of William to swear that he renounced all hope of the crown, and to do homage for his lands and honors to William, as the appointed successor of Edward. He returned to England, and, as Hume says, deterred the king from abdicating in favor of William, increased his martial renown by an expedition against the robbers of Wales, which terrified them into submission during the next 4 reigns, extended his sway by marrying the sister of Morcar of Northumberland, and was crowned king on the very day of Edward's death. It was fortunate for the memory of Edward that he occupied the interval between the Danish and the Norman conquests; that his reign was a time of comparative tranquillity under a native prince, between two periods of subjection to conquerors. The laws and customs of "good King Edward" were long remembered with popular affection. He was highly esteemed for his sanctity, was the first English prince that touched for the king's evil, and was canonized

and styled "the Confessor" about a century after his decease. The most commendable feature of his government was his attention to the administration of justice, and to collecting the laws of the realm. His compilation is lost.

EDWARD I. (of the Norman line), king of England, surnamed Long Shanks, from the excessive length of his legs, son of Henry III. and of Eleanor of Provence, born in Westminster, June 16, 1239, crowned Aug. 19, 1274, died July 7, 1307. Being invested with the duchy of Guienne, his right to that province was disputed by Alfonso X., king of Castile, who, however, renounced his claim in consequence of Edward's marrying his sister. In 1254 he received the lordship of Ireland and of the provinces which had been seized in the reign of John Lackland by the king of France. He supported the throne against the revolted barons, and was with his brother Richard I. made prisoner at the battle of Lewes in 1264. He recovered his liberty in 1265, defeated and slew Simon de Montfort, earl of Leicester, at Evesham, and in 1267 conquered the last of the insurgents in the isle of Ely. He now joined the crusaders, and served 2 years in the East. Nearly 2 years after his father's death, he was crowned without opposition at Westminster, and began to signalize his ability both as a warrior and legislator. His arms were first directed against Llewellyn, prince of the Welsh, whom he reduced, but who rebelled again, and was slain in single combat by an English knight immediately after the army of Edward reappeared in that country. It is said that Edward caused the massacre of all the bards of Wales, for fear that their songs should revive the patriotism of their countrymen; but this story may have been invented in view of the strict censorship which he exercised over the national poetry. He established corporate bodies of merchants in the principal towns of Wales, and introduced the jurisprudence of the English courts. In the castle of Caernarvon his queen Eleanor was delivered of her son Edward; the natives claimed the child as their countryman, and he was declared prince of Wales, a title which has since always been borne by the eldest son of the sovereign. In 1289 he resolved upon the subjugation of Scotland, to the crown of which there were at this time 13 claimants. Being invited to the office of arbitrator, he first took possession of many of the Scotch fortresses, and then conferred the crown upon John Baliol, who soon renounced his allegiance. Edward marched again across the Tweed, gained a great victory at Dunbar in 1296, sent Baliol into exile in Normandy, bore away the Scotch sceptre and crown, and left the highest offices of government in the hands of Englishmen, under the earl of Surrey, who received the title of guardian of the kingdom. The Scots rallied in 1297 under the chieftain William Wallace, and drove the English out of their kingdom, totally defeating them in the battle of Stirling, Sept. 11. Edward hastily finished the war which he had in the mean time

undertaken in France, advanced again to the Forth, and defeated the insurgents with the loss of from 20,000 to 40,000 men near the forest of Falkirk, July 22, 1298. Wallace himself escaped. The rebellion again broke out in 1303, and again Edward overran the kingdom, its temporary subjugation being completed by the surrender of the strong castle of Stirling in 1305. Wallace was soon after surprised and captured, and was hanged in Smithfield. In 1306 the war was again kindled by Robert Bruce, who was elected king, and though at first unsuccessful, at length gained a decisive victory over the earl of Pembroke. Edward, now enfeebled by age and disease, marched again to the north with the purpose of rendering Scottish rebellion from that time impossible; but he was surprised by death on the frontier at Burgh-upon-Sands. The most enduring results of the reign of Edward were the reforms which he introduced in the administration of government, of justice, and of the finances, which have gained for him the title of the "English Justinian." He ameliorated the laws, confirmed and finally established the two great charters, gave to the parliament the form which it has since retained, and is said to have first instituted justices of the peace. The Jews, who during the whole period of his reign were objects of the bitterest hatred to the great mass of the people, were cruelly despoiled, and in 1290 ordered under penalty of death to quit England for ever before a certain day.

EDWARD II., king of England, son and successor of the preceding, born in Caernarvon, April 25, 1284, ascended the throne in 1307, murdered Sept. 27, 1327. He was of an irresolute character and dissipated habits. From his childhood he had lived in close intimacy with Piers de Gaveston, the son of a gentleman of Guienne, who had at length been banished from the kingdom as a corrupter of the prince. Edward I. on his deathbed forbade his son under pain of his paternal malediction to allow the vicious favorite to return into England; yet the first act of the new king was the recall of Gaveston, whom he created earl of Cornwall and married to his own niece, and to the scandal of the whole kingdom appointed him regent while he himself went to France to marry the princess Isabella. A formidable league under the earl of Lancaster forced Gaveston into exile; but instead of being disgraced, he was appointed lieutenant of Ireland, and accompanied for some distance on his way by his royal friend. He returned soon after, when an army raised by confederate powerful barons and commanded by the earl of Lancaster pursued him to the north; he was besieged and captured at Scarborough, and, without any pretence of a legal process, was executed. Edward, at first threatening vengeance against all who had taken a part in the death of his favorite, seemed soon to forget his friendship and his hatred, and turned his attention to the revolted Scots. At the head of an immense army he crossed the frontier, but after losing the battle of Bannock-

burn fled from the kingdom with a body of Scottish cavalry at his heels. In 1321 he was again defeated at Blackmoor, and pursued even to the walls of York. The public discontent was increased by the honors bestowed upon Hugh Spenser, a new favorite, and an armed insurrection of the barons under the earls of Lancaster and Hereford caused the Spensers to be banished; but on their return Lancaster was seized and put to death with the same indignities which had formerly by his orders been exercised against Gaveston. Edward, now at peace with his own subjects, hoped to secure his tranquillity by negotiating in 1323 a truce for 18 years with Scotland. Though the triumph of the Spensers was complete, the partiality with which the king regarded his favorites had the effect of alienating not only his subjects but also his queen. Under pretence of arranging some differences between her husband and her brother she went to France, where she found a great number of English fugitives, the friends of Lancaster, the most considerable and potent of whom was the young Roger Mortimer. A domestic rebellion supported by a foreign invasion was projected, and in 1326 the queen with a foreign force of 8,000 men, led by Hugh Mortimer and John of Hainaut, landed on the coast of Suffolk. The most powerful nobles and prelates hastened to meet her, and Edward, having in vain appealed to the citizens for support, was obliged to retreat to the marshes of Wales. The queen pursued him, and he took shipping for Ireland, but, unlucky by sea as well as by land, was driven back by contrary winds, was found concealed in the mountains of Wales, and sent in custody to the castle of Kenilworth. The favorite Spenser was taken at the same time and hanged. The parliament being assembled, by the influence of Isabella and Mortimer, it was resolved that the reign of Edward of Caernarvon had ceased. While imprisoned in Berkeley castle under the charge of ruffians employed by Mortimer, Edward II. was found dead in his bed in the morning after shrieks had been heard from his apartment during the night, and his distorted features betrayed the agony in which he had expired.

EDWARD III., eldest son of Edward II. and Isabella of France, born at Windsor, Nov. 13, 1312, proclaimed king of England, Jan. 25, 1327, died at Shene, now Richmond, June 21, 1377. At the age of 12 years he went with a splendid retinue to France to do homage to Charles IV. for the possession of Guienne and Ponthieu, which had been resigned to him by his father. He remained with his mother at the French court, was contracted in marriage by her to Philippa, daughter of the count of Hainaut, accompanied her and her followers in their invasion of England, and was declared king after the captivity of his father. A council of regency, consisting of 4 bishops and 10 noblemen, most of whom, being of Isabella's party, gave up to her and Mortimer (now created earl of March) the ascendancy in the government,

had but just been appointed, when Robert Bruce, in violation of the truce between Scotland and England, sent an army of 24,000 men under Randolph and Douglas, which ravaged the county of Cumberland. Young Edward marched to the north with over 40,000 men, made a vain pursuit of the Scots, came up with them twice when they were in inaccessible positions, is recorded to have wept when he found himself out-generalled by the skill of an inferior enemy, and concluded an inglorious campaign by a treaty in which the entire independence of Scotland was recognized. The odium of this settlement was thrown upon Isabella and Mortimer, who increased their unpopularity by intrigues against the earl of Kent, whom they caused to be executed for high treason in 1330. At the age of 18, Edward, having determined to assert his own authority against his mother and her favorite, contrived their arrest. Mortimer was executed for high treason at Smithfield, and Isabella was confined for the rest of her life in the manor of Risings. Immediately after assuming the government he renewed his father's and grandfather's project of conquering Scotland, and secretly encouraged the claim of Edward Baliol to the crown of that country, who was willing to hold it as a fief of the English monarch. Baliol won the crown and lost it within 8 months, and the incursions of the Scots gave to Edward the pretext which he desired to renew the war and attempt to restore the refugee. He laid siege to Berwick, and (July 19, 1333) defeated on Halidon hill with great loss the army of the regent Douglas, who had approached for its relief. The town and castle were immediately surrendered, and Baliol being again seated on the throne of Scotland dismembered the kingdom by a large cession of territory to England, a measure which was followed by his flight to England within 4 months. Three times Edward invaded and devastated Scotland in support of Baliol, but had not conquered the independent spirit of the country when he suffered the war to languish, having determined to lay claim to the crown of France against Philip of Valois. The ground of this pretension was, that although females were excluded from the French throne, the male descendants of females were not; and that as the son of Isabella, the daughter of Charles IV., his claim was better than that of Philip, who was descended from a younger brother of Charles IV. To carry his mighty design into execution, he made alliance with several continental princes and rulers, the chief of whom were Louis of Bavaria, emperor of Germany, the dukes of Brabant and Gueldres, and Artevelde of Ghent. Edward formally published his claim in 1337, and in the following year sailed with a numerous fleet to Antwerp, designing to begin the campaign with the siege of Cambrai; but perceiving the difficulty of the enterprise, he advanced into France with about 50,000 men, was almost confronted with an army of nearly double the force under Philip, yet no engagement ensued, and he at

length returned to Brussels and disbanded his army without having derived any advantage from his immense expenditures. He returned to England in 1340, obtained an unprecedented grant from parliament, defeated a French fleet off Sluis which Philip had sent to intercept him, returned to the continent, and at the head of 200,000 men undertook at the same time the sieges of Tournay and St. Omer, both of which were unsuccessful; and he quickly concluded an armistice for 9 months, and soon after another for 3 years and 8 months. Another English campaign in France was begun in 1346 under the earl of Derby, and prosecuted with uninterrupted success. Edward also landed with a numerous force on the coast of Normandy, advanced to Rouen, sent his light troops to insult the faubourgs of Paris, and on Aug. 26 gained over Philip the decisive battle of Crécy. The siege of Calais followed, and while the chivalry of England lay before the walls of that city, the Scots suddenly crossed the frontiers, but were defeated by a miscellaneous and rapidly collected army, led, according to the improbable testimony of Froissart, by Queen Philippa. Calais surrendered after an obstinate defence, and a truce followed which lasted till 1355. Meantime, Edward invaded and widely desolated Scotland, causing a havoc long remembered by the natives. The war was renewed in France under the Black Prince, who gained in 1356 the memorable victory of Poitiers, in which he took King John of France prisoner, who was not ransomed till 1360. In that year the "great peace" was concluded at Bretigni, by which Edward renounced his pretensions to the crown of France and restored his conquests, retaining only the full sovereignty of Poitou, Guienne, and the county of Ponthieu. Though the misfortunes of the latter years of his reign contrasted strongly with the glories of its commencement, and though his victories left few lasting acquisitions, yet they gave to England a lustre and renown which were long her strength and safety. In his reign the elegant arts began to be cultivated, the castle of Windsor was rebuilt, the order of the garter was instituted, and English poetry and prose may be said to have begun.

EDWARD IV., king of England, born in Rouen, April 29, 1441, died April 9, 1483. An old chronicler speaks of "the troublous season of King Henry VI., the prosperous reign of King Edward IV., the pitiful life of King Edward V., and the tragical doings of King Richard III." The lot of the feeble Henry VI. fell most inappropriately in an age of violence, to which he brought only meekness of spirit; and he saw during his reign the splendid achievements of foreign victory exchanged for defeats and ignominy, his title to the throne disputed, and England torn to pieces by civil war. His own insignificance, the dishonor of the English arms, and the passionate tyranny of his indomitable queen, Margaret of Anjou, were the occasion of reviving the long forgotten pretensions

of the house of York. The great Lancastrian chiefs, Cardinal Beaufort and the dukes of Bedford and Gloucester, who ably though discordantly supported the throne during the minority of Henry, were dead, when Richard, duke of York, the father of Edward IV., returned from Ireland, cautiously and gradually advanced his claim to the throne, gained the support of the powerful earls of Warwick and Salisbury, took arms against Somerset, the last great nobleman of the Lancastrian branch, and began by a victory at St. Albans, in 1455, the wars between the red rose of Lancaster and the white rose of York. The claims of both these Plantagenet lines were derived from Edward III. From the first 2 sons of that sovereign no issue survived; the 3 Lancastrian kings who had occupied the throne for more than half a century were descended from the 4th son; the dukes of York were descended from the 5th son, but had also by intermarriage become heirs to the rights of the 3d son. The question of genealogical right, complicated in itself, was rendered more so by the irregular accession of the 1st Lancaster, while Edmund Mortimer, the heir of the 3d son, was alive, and by decrees of parliament. Richard, duke of York, after various successes and reverses in maintaining his claim, was defeated and slain by Queen Margaret, at Wakefield, in 1460; and young Edward, the inheritor of his father's pretensions and ability, immediately put himself at the head of an army of Welsh borderers and mountaineers, and defeated a formidable force under the earls of Pembroke and Ormond, at Mortimer's Cross. He then marched southward, supported by the earl of Warwick, who suffered a defeat at Barnet Heath by which Henry was again restored to his friends. Edward marched directly to London, which he entered without opposition, and where his youth, boldness, and beauty gained him the public favor. He was proclaimed king in 1461, and thus there were two kings and two royal armies in the land. Both parties made the most formidable preparations for battle, and at Towton, near York, 100,000 Englishmen were drawn up, in not very unequal division, in hostile array. Proclamation had been made that no quarter should be given, and the battle was probably the bloodiest in English history. It lasted more than a day, and ended, after the slaughter of more than 30,000 persons, in the total rout of the Lancastrians; and thus the crown was firmly placed on the brow of Edward IV. The cause of the red rose seemed desperate, but it was supported by the courage and energy of Margaret. She sailed to France, seeking the alliance of the French king; and perils by land and by sea, shipwreck, and capture by roving banditti, make up the wild story of her adventures, till in 1464 she appears again in Scotland, at the head of only 500 French troops, with whom, and a band of Scottish borderers, she gave battle to the English general, Lord Montacute, near Hexham. The Lancastrians were again com-

pletely routed; the king and many of the chiefs were captured on the field, or after lurking for a while in concealment; and Margaret again made her escape through Scotland into France, with her son and his famous preceptor, Sir John Fortescue. Edward, acting upon the maxim of Macchiavelli, with characteristic vigor, made a terrible slaughter of his enemies in the first moment of victory, and in his subsequent administration ruled with clemency. After this second retreat of Margaret, he devoted himself for a time to pleasure. He had been hunting in the forest of Grafton, when he met, at her father's house, Elizabeth, widow of Sir John Grey and daughter of Richard Widville, Baron Rivers. The impetuous king, in vain seeking an illicit union, consented to a private marriage with her (April, 1464), and she was within a year publicly acknowledged queen, and her father was made an earl. This union displeased the powerful and haughty earl of Warwick, who had before been authorized to negotiate for the marriage of the king with the princess Bonne of Savoy, and who was moreover indignant at the influence possessed by the new queen, which she employed in the elevation of her own friends. The malcontent earl, allying himself with Edward's brother, the duke of Clarence, broke out into open revolt in 1469. The effect of his combination with the discontented nobility and gentry was quickly seen in seditions fomented in every part of the country. In Yorkshire, Robin of Redesdale, a hero among the troopers of the frontier, took the field with 60,000 men. Edward marched against them, unaware of the danger to which he exposed his capital. Warwick, absent in France, had gained the favor of Louis XI., and had even become reconciled with his old enemy, Margaret. He landed at Dartmouth with a small body of troops, where his popularity swelled his army in a few days to more than 60,000 men. He advanced to the north, and his approach shook the fidelity of the royal troops. Edward fled in 1470 to Holland, and his imprisoned rival was led forth from the tower to hear the streets of London resounding once more with the name of King Henry. A parliament was summoned in the name of the restored king, by which Edward was pronounced a usurper, his adherents were attainted, and all acts passed by his authority repealed. This restoration gave, however, but a brief respite to the Lancastrian family. The fugitive Edward, secretly assisted by the duke of Burgundy, collected a body of Flemings and Dutchmen in a few months, with whom he entered the Humber, and landed at Ravenspur. He advanced into the interior, pretending at first that he came only to recover his patrimony as duke of York, and making his followers cry "Long live King Henry," till he received reinforcements which put him in a condition to face the enemy. The adverse armies met at Barnet, on Easter morning, April 14, 1471, and the Lancastrians were defeated and Warwick himself slain. Edward

now again became master of London, and of the person of Henry, who was remanded to the tower, never again to leave it. Meanwhile, Margaret, with her son, now 18 years of age, landed at Weymouth at the head of a body of French troops on the very day of the battle of Barnet. The first event of which she received tidings was her husband's captivity and the defeat and death of Warwick. Nevertheless, she determined to defend to the utmost her fallen fortunes, and with an army commanded by the duke of Somerset made a stand at Tewkesbury, May 4, 1471. Her army was defeated, her son Prince Edward slain, and she herself taken prisoner and held in captivity 5 years, when she was ransomed by the king of France. Her husband was put to death in the tower, May 21. Edward formed an alliance in 1474 with the duke of Burgundy, by which France was to be divided into two states, one of which, comprehending the northern and eastern provinces, should belong to Burgundy, and the other should be possessed by England. He passed over to Calais with a force of archers and men-at-arms, only, however, to be disappointed by the duke of Burgundy, who sent his apology instead of an army, and to make an advantageous treaty with Louis without a battle. By this treaty pensions of considerable amounts were bestowed by Louis not only upon the English king, but also upon all the considerable persons of the English court. Edward returned to England to become involved in a bitter strife with his brother Clarence. The interference of Edward prevented the marriage of Clarence with the wealthy heiress of Burgundy; soon afterward two of the friends of Clarence were put to death upon a frivolous pretence, joined with an accusation of sorcery; and when he maintained their innocence, he was himself privately put to death, Feb. 1478, upon a charge of treason, for arraigning public justice. During the latter part of his life Edward was sunk in indolence and pleasure. He left 5 daughters, of whom Elizabeth was afterward married to Henry VII.; and 2 sons, the ill-fated princes Edward and Richard.

EDWARD V., king of England, of the York branch of the Plantagenets, son and successor of the preceding, born Nov. 4, 1470, in the sanctuary of Westminster abbey, whither his mother had fled for refuge from the army of the Lancastrian Queen Margaret and of Warwick, died doubtless by murder in the tower of London, where he was imprisoned, in 1483. At the time of his father's death, April 9, 1483, young Edward was residing on the borders of Wales, in the care of the earl Rivers, brother of the queen. In company with Rivers he immediately set out for London, while the duke of Gloucester, the brother of the late king, and now the regent during the minority, started for the south from York, attended by a splendid retinue. The two processions met at Stony Stratford, when Gloucester approached the young prince with the greatest demonstrations of respect but soon after charged

Rivers and the queen's son, Sir Richard Grey, with having aimed to estrange from him the affection of his nephew, arrested and imprisoned them both in the castle of Pomfret, and endeavored unsuccessfully to satisfy Edward with regard to the violence thus exercised upon his kindred. The king was from this time a captive. The queen mother in London, perceiving that nothing less than the ruin of her family was intended, hastily took refuge with her second son, the duke of York, and her 5 daughters, in the sanctuary at Westminster. Gloucester had no sooner arrived in London than he postponed the coronation of the young king, confined him for security in the tower, and was formally invested with the office of protector. His next step was to withdraw the duke of York from his retreat with his mother at Westminster; but he had still to fear opposition on the part of those noblemen, such as Lords Hastings and Stanley, who were friends of the late king, and unswerving in their fidelity to his children. Their destruction or imprisonment without form of trial, or even specification of offence, swiftly followed. The earl Rivers also, and his friends, were put to death without any semblance of judicial forms. The amours of the late king now suggested to Gloucester a means of vilifying the queen dowager and her descendants. He even did not hesitate to malign his own mother, affirming that the resemblance of Edward IV. and of the duke of Clarence to notorious gallants was a sufficient proof of their spurious birth, and that the duke of Gloucester alone, of all his sons, appeared by his features and countenance to be the true offspring of the duke of York. Thus having insulted the memory of his mother and brother, disgraced the queen and her children, and removed their most powerful friends, he openly denied the title of Edward V., who meanwhile, with his brother, languished in prison. The precise time and the details of the death of these princes are among the mysteries of history. A conspiracy had been set on foot for their liberation during the first year of the usurper's reign, when it was announced that they were no longer alive. The account of Sir Thomas More, which was collected from the confession of the murderers in the next reign, is as follows: that Richard had in vain tampered with the governor of the tower, Brackenbury, to put them to death, but found a ready instrument for the execution of his purpose in Tyrrel, his master of horse; that Tyrrel was despatched with a commission to receive the keys of the tower for one night, and that during that night he watched without while one of his grooms, accompanied by a notorious assassin, entered the sleeping room of the princes, stifled them both with feather beds and pillows, and buried their bodies at the foot of the staircase. The testimony of More is almost contemporaneous with the event itself, and is confirmed by the honors which were certainly conferred upon the alleged murderers. In the reign of Charles II., when alterations were made in the tower, there was found at the foot

of an old stairway a heap of decayed bones, which proved to be those of two boys. The indications were deemed sufficient that they belonged to the unfortunate Edward V. and his brother, and they were removed by royal command to Westminster abbey, where an inscription, beginning *Ossa desideratorum diu et multum quasita*, was placed upon the monument. So well concealed a matter as the death of the royal princes leaves room for paradoxes and historic doubts; but it is certain that, though the name of Edward V. stands on the list of English sovereigns, he had hardly the shadow of a reign; that under the dark protectorship of his uncle he went speedily from the palace to the prison, within whose precincts he found secret death and burial.

EDWARD VI., 3d king of England of the Tudor dynasty, born Oct. 12, 1537, ascended the throne in 1547, died July 6, 1553. The son of Henry VIII. and Jane Seymour, he was little cared for by the 3 stepmothers whom he had in quick succession; but at the age of 6 years, being intrusted to the learned masters Anthony Cooke and John Cheke, made progress in philosophy, divinity, Greek, and Latin. Henry VIII. appointed in his will a council of executors to exercise the royal authority during the minority of his son, who, at their first meeting, fearing that the government would lose its dignity for want of some head to represent the royal majesty, bestowed upon Edward Seymour, now created duke of Somerset, or allowed him to assume, the titles of governor of his majesty, lord protector of all his realms, and lieutenant-general of all his armies. The chancellor Wriothesley, who resisted this measure, and who in his zeal exceeded his judicial duties, was compelled to resign his office. Sir Thomas Seymour, the brother of Somerset, was created Baron Seymour of Sudley, and appointed lord high admiral. The government was almost entirely Protestant, and its first object was to complete the religious revolution and establish a church independent of the see of Rome. The statute of the 6 articles was repealed, prisoners under it were released, and exiles recalled. Preaching, which had been rare in Catholic times, was enforced by visitors despatched throughout the kingdom, who with other powers were authorized to require that 4 sermons be preached every year in every church against the papacy. Images, which Luther had tolerated as aids to devotion, and of which Cranmer vindicated a moderate use, became objects of dislike, and were torn down in places where they had been honored by pilgrimages and offerings. The English Bible, with Erasmus's commentary on the gospels, was placed in every church for the use of the people. In the first parliament the statutes of Richard II. and Henry IV. against the Lollards were repealed, together with all the acts in matters of religion passed under Henry VIII., except those directed against the papal supremacy. The uniformity of public worship was established, and all ministers were

enjoined to use only the book of common prayer, prepared by the primate Cranmer and his brethren, which, after various alterations in the reigns of Elizabeth, James I., and Charles II., continues in use in the Anglican church to this day. The English clergy were emancipated from compulsory celibacy, though it was recommended to them "to live separate from the bond of marriage, for their own estimation, and that they might attend solely to the ministration of the gospel." There were as yet no Protestant nonconformists, but all persons were commanded to attend public worship under pain of ecclesiastical censures, of 6 months' imprisonment for the first offence, 12 for the second, and confinement for life for the third. Bonner, bishop of London, Gardiner, bishop of Winchester, and several others, were deprived of their sees because they could not keep pace with the reformatory movement. The first step toward religious liberty was a distinction, recognized practically though not by canon, between what were supposed to be the essential and the unessential parts of Christianity, and only offences against the former were liable to deadly persecution. Thus, no Roman Catholic suffered death for religion in this reign; but Joan Bocher, commonly called Joan of Kent, was burned for an unintelligible heresy, which denied something, though her words vainly struggled to explain what, concerning Christ. Von Parris, a Dutchman, was also burned for denying the divinity of the Saviour. Among civil occurrences in this reign, the first of importance, after the settlement of the government, was the expedition of Somerset into Scotland to compel the marriage of Mary, the young queen of Scots, to Edward, according to a previous treaty. A bloody encounter, begun between the Scottish and English cavalry at Falside, Sept. 9, 1547, was continued the next day between the entire armies at Pinkie, and ended in the victory of the English protector. He was, however, quickly called home by machinations against him, the young queen of Scots was sent to France, and the war was ended without having effected its object. His brother and rival, Lord Seymour, was committed to the tower, Feb. 25, 1549, and a bill attainting him was brought into the house of lords. This bill was, by the influence of Somerset, who was present in the house to encourage it, passed unanimously within 3 days; and Seymour, without having had an opportunity to defend himself or confront his accusers, was beheaded on Tower hill, March 20. During the next summer formidable insurrections broke out in various parts of the kingdom. The depreciation of the currency during the last reign had been followed by an advance in the price of commodities; at the same time the demand for labor had been lessened and its wages reduced. The new owners of abbey lands had enclosed many of the fields which had formerly been allotted for the common use of the poor inhabitants, and their rapacity was compared with the indulgence of the monks, who had often been the most lenient of

landlords. There were armies of insurgents in several counties, but the largest and most violent was in Cornwall, where a tanner named Kett encamped near Norwich at the head of 20,000 men. He repulsed the marquis of Northampton, but was at length defeated and hanged with his principal associates. The protector had incurred odium by what was termed his feeble administration during this rebellion, and also by his lavish expenditures upon his magnificent palace of Somerset house. He had wavered and almost given sanction to the demands of the populace when they were in arms against the royal authority; and had become from a simple knight with a slender fortune the possessor of more than 200 manors and parcels of land in different parts of the kingdom. The discontented lords, directed by Dudley, earl of Warwick, gradually withdrew from court and met in London with bodies of their retainers. The protector, as soon as he received intelligence of their movement, took the king with him to Windsor, and called by proclamation on all faithful subjects to repair to him at Hampton court in arms for the protection of the royal person against a conspiracy. Multitudes of the common people, but scarcely a gentleman, obeyed his summons, and his cause was rendered desperate when the council declared against him. The king was obliged to sanction the vote for his deposition, and he was brought to London and incarcerated in the tower, Oct. 14, 1549. Warwick dissembled for the moment his purpose concerning the prisoner, and was obliged by his position, though a secret Catholic, to favor the cause of the reformation, and, though a rancorous enemy of Somerset, soon to set that nobleman free, and to give his own son in marriage to Somerset's daughter. When, however, Warwick had received the office of lord high admiral, had been raised to the dignity of duke of Northumberland, had become the undisputed chief of the government, and had annihilated the power of Somerset, he was able to proceed further against that duke, who was again committed to the tower in 1551 for treason and for felony, was convicted upon the latter charge, and executed upon Tower hill, Jan. 22, 1552. Warwick next persuaded Edward to make a new settlement excluding his sisters from the succession to the throne, and giving the fatal nomination to Lady Jane Grey, who had been his playmate and companion in studies. Edward sank rapidly after this, and died in the 16th year of his age and the 7th of his reign. His accomplishments were such as to surprise the famous Italian physician Jerome Cardan, who visited him in his last sickness; and for his diary and other compositions he is included by Walpole in his list of royal authors. The literary remains of Edward VI., edited with historical notices and a biographical memoir by John Gough Nichols, were printed in 1859, for the Roxburgh club (2 vols., London).

EDWARD, prince of Wales, surnamed the Black Prince, from the color of his armor, eldest son of Edward III. and Philippa of Hainaut,

born at Woodstock, June 15, 1330, died June 8, 1376. In his 16th year he accompanied his father in his invasion of France, and he held the nominal command of the largest and most actively engaged division of the English forces in the battle of Crécy, the king giving him this opportunity to "win his spurs." Among the slain in the battle was John of Luxemburg, king of Bohemia, and his crest of 3 ostrich feathers, with the motto *Ich dien* (I serve), was adopted by the prince of Wales, and has always been borne by his successors. In 1356 he gained the victory of Poitiers, in which the French King John was taken prisoner. He returned to England in 1357, the king of France on a splendidly caparisoned charger forming the principal ornament of the cavalcade with which he entered London. In 1361 the king of England united all his dominions between the Loire and the Pyrénées into one principality, and bestowed it upon the Black Prince, with the title of prince of Aquitania. There Pedro the Cruel took refuge from Castile, and young Edward undertook to replace him on his throne. He marched through the valley of Roncesvalles and by Pamplona to the frontiers of Castile, met and defeated Henry of Trastamare on the plains between Navarrete and Najera, was disappointed of the reimbursements which had been stipulated, and returned into Guienne with an exhausted treasury and a shattered constitution. To defray the expenses of his court, perhaps the most magnificent in Europe, and to fulfil his contracts with the troops that had followed him to Spain, he was obliged to impose taxes which made him unpopular with his barons. Summoned in 1369 to answer before King Charles of France to the complaints of his vassals, he replied that he would obey, but at the head of 60,000 men. He appeared in the field, but the French generals avoided an engagement and garrisoned their strong places. He laid siege to Limoges, captured it and reduced it to ashes, and massacred the inhabitants. This was the close of his military career, and by the advice of his physicians he returned to England, where he lingered for 6 years. The Black Prince is portrayed by contemporary writers as the mirror of knighthood and the most heroic of princes. He was married to his cousin Joan, countess of Kent, famed for her beauty, by whom he left one son, Richard, who succeeded Edward III. on the throne of England.

EDWARDES, LIEUT. COL. HERBERT BENJAMIN, C. B., an English soldier, born in Frodesley, Shropshire, in Jan. 1820, where his father was rector of the parish. He studied at King's college, London, and having been nominated to a cadetship in the East India company's service, set sail for Calcutta, where he arrived in Jan. 1840, and was immediately attached to the 1st European regiment. In 1845 he was appointed aide-de-camp to the commander-in-chief, Sir Hugh Gough; he was wounded at the battle of Moodkee, Dec. 18; was actively engaged in the victory of Sobraon, Feb. 10, 1846; was

appointed 3d assistant to the commissioners of the Trans-Sutlej territory a few weeks later; and in Jan. 1847, was made first assistant to Sir Henry Lawrence, the resident at Lahore, and was charged with collecting the revenue in the N. W. part of the Punjab. The skill with which he performed this difficult duty, and, without resort to military measures, reduced the lawless tribes of that half subjugated country, at once drew the attention of the Indian authorities toward the young lieutenant; and his conduct in the troubles which followed with the Sikh chieftain Lalla Moolraj soon made his name familiar in every part of England. In April, 1848, Moolraj stirred up a rebellion of the Sikhs, fortified himself at Mooltan, and, aided by the native garrison of a small fort near there, murdered Lieut. Anderson of the Bombay fusileers and Mr. Vans Agnew of the Bengal civil service. At this critical period it was probably the courage and military knowledge of Lieut. Edwardes which saved the British power in the Punjab. Leaving the town of Leia on the Indus, where he had been employed with a small force in collecting the land tax, he summoned Col. Cortlandt, commanding at Dera Ismail Khan, to come to his assistance, called upon the friendly nabob of Bahawalpoor to take the field, and having effected a junction with Cortlandt, May 20, moved down the W. bank of the Indus at the head of 7,000 men. At the same time 10,000 of the enemy who had marched out to oppose his passage were compelled by the demonstrations of the Bahawalpoor troops to retreat toward the Chenaub, whither Edwardes, having crossed the Indus on the 17th with a small body of infantry, hastened to attack them, leaving Cortlandt to follow as soon as boats could be got for the passage of the rest. Meanwhile Moolraj had defeated the nabob of Bahawalpoor, and Edwardes on reaching the scene of action had to withstand the onset of the whole Sikh army, 12,000 strong, including horse and artillery. After a hard-fought battle, memorable for a gallant charge of the mounted British officers upon the Sikh front, the insurgents were routed by the opportune arrival of Col. Cortlandt, and made their way to Mooltan. In the subsequent siege of that city and its assault after the arrival of Gen. Whish from Lahore, the heroic young officer gained new laurels, but lost his right hand by the accidental discharge of a pistol. For his services he received the local rank of major in the Lahore territories, the East India company voted him an annuity of £100, the court of directors caused a gold medal to be struck in his honor, and he was raised by successive promotions to the rank of lieutenant-colonel. At the end of the war he visited England, was married, was created by special statute an extra member of the companions of the order of the bath, Oct. 20, 1849, published his "Year on the Punjab Frontier" (2 vols. 8vo., London, 1851), and in 1851 returned to India, where he was appointed commissioner and superintendent at Peshawar, an office which he still holds. After

the disarming of the troops at this station during the sepoy revolt of 1857-'8, he organized an effective force among the Afghan mountaineers of the frontiers, and was mainly instrumental in preserving the comparative tranquillity of that part of India throughout the rebellion.

EDWARDS, a S. E. co. of Ill., drained to a small extent by the Little Wabash river; area, 200 sq. m.; pop. in 1855, 4,598. Bon Pas creek flows along its E. border, and the Wabash touches it on the S. E. The surface is occupied by forests and fertile undulating prairies. In 1850 the productions were 227,035 bushels of Indian corn, 86,412 of oats, and 1,502 tons of hay. There were 11 churches, and 1,054 pupils attending public schools. The county was named in honor of Ninian Edwards, governor of Illinois territory. Capital, Albion.

EDWARDS, BELA BATES, D.D., an American author, professor in the Andover theological seminary, born in Southampton, Mass., July 4, 1802, died in Georgia, April 20, 1852. He was graduated at Amherst college in 1824, entered the seminary at Andover in 1825, in 1826 was appointed tutor at Amherst, in 1828 was chosen assistant secretary of the American education society, and performed the duties of this office till 1833. His literary and editorial labors were very great and important. From 1828 to 1842 he edited the "American Quarterly Register," which, up to the first date, had borne the name of the "Quarterly Journal of the American Education Society." In 1833 he established the "American Quarterly Observer," which, after 8 volumes, was united with the "Biblical Repository" of Prof. Robinson, which he edited from 1835 to 1838. Of the "Bibliotheca Sacra" he was the editor from 1844 to 1852. In 1837 he was appointed professor of Hebrew in the seminary at Andover; and in 1848 successor to Prof. Stuart in the chair of biblical literature, which office he held till his death. For 23 years he superintended an important part of our periodical literature, and, with the aid of others, produced 81 octavo volumes, monuments of his industry, learning, taste, and talents. He also prepared the "Eclectic Reader," "Biography of Self-taught Men," and the "Missionary Gazetteer." A selection of his sermons, lectures, and addresses, with a memoir by Prof. Park (2 vols. 12mo.), was published in Boston in 1853.

EDWARDS, BRYAN, an English historian, born in Westbury, Wiltshire, May 21, 1743, died July 15, 1800. After acquiring a good English education at Bristol, he emigrated to Jamaica in 1759, where a rich uncle gave him the means of completing his studies, and finally made him his heir. He became a prominent member of the colonial assembly, and published in 1784 a pamphlet against the restrictions laid by government on the trade between the West Indies and the United States. He afterward went to St. Domingo, and collected materials for his "Historical Survey of the French Colony" in that island, which was published in 4to. (London, 1797), and was subsequently incorporated in the author's

best known work, the "History, Civil and Commercial, of the British Colonies in the West Indies" (8 vols. 4to., London, 1793-1801). This work bears a high character, and gives very minute and varied information. It was reprinted in Philadelphia in 4 vols. 8vo. (1805-'6). A 5th edition, with a continuation to 1796, was published in 5 vols. 8vo. (London, 1819). Mr. Edwards returned to England, took up his residence at Polygon, near Southampton, and from 1796 till his death represented the borough of Grampound in parliament.

EDWARDS, GEORGE, "the father of ornithologists," born in Stratford, Essex, Eng., April 8, 1694, died July 28, 1773. He was brought up to trade, but his tastes being developed by the perusal of works on natural history and antiquities, at the close of his apprenticeship he travelled abroad, visiting Holland, Norway, and other parts of Europe, in prosecuting his favorite researches. The fruit of his labors appeared in his "Natural History of uncommon Birds, and of some rare and undescribed Animals" (4 vols. 4to., London, 1743, '47, '50, and '51); to which 8 more volumes were added in 1758, '60, and '64, called "Gleanings of Natural History." This exceedingly valuable work contained numerous plates, with descriptions in French and English of over 600 subjects; in its original form it is very scarce, but several partial editions, abridgments, &c., have been published. Mr. Edwards left a work entitled "Elements of Fossilology," which appeared in 1776.

EDWARDS, JOHN, D.D., a divine of the church of England, born in Hertford, Feb. 26, 1637, died in Cambridge, April 16, 1716. He was graduated at Cambridge in 1661, and soon afterward took charge of Trinity church in Cambridge, thence removed successively to Bury St. Edmund's, to Colchester, and back again to Cambridge. In 1699 he was made doctor of divinity; and from this time he became a voluminous writer, showing himself a subtle and able polemic, and thoroughly versed in ecclesiastical history. He was so decided a Calvinist that he has been called "the Paul, the Augustine, the Bradwardine, and the Calvin of his age;" and such was his abhorrence of Arminianism that he contended, with the old Puritans, that it was closely connected with popery. His published works were very numerous, and they evince extensive learning, deep thought, cogent reasoning, and extraordinary zeal for what are known as the doctrines of grace. The most important of his works are "*Veritas Redux*, or Evangelical Truths Restored;" "Inquiry into four remarkable Texts;" "Discourse concerning the Authority, Style, and Perfection of the Books of the Old and New Testaments;" "Survey of the several Dispensations of Religion;" "Answer to Dr. Whitby's Five Points;" "Animadversions on Dr. Clarke's Scripture Doctrine of the Trinity;" "*Theologia Reformata*: the Body and Substance of the Christian Religion;" several treatises against the Socinians, and a vast number of smaller treatises, pamphlets, &c.

EDWARDS, JONATHAN, an American divine and metaphysician, born at East Windsor, in the colony of Connecticut, Oct. 5, 1703, died at Princeton, N. J., March 22, 1758. He was the first of the sons of Connecticut, the greatest theologian of his century, and the ablest metaphysician of the period between Leibnitz and Kant. Thomas Chalmers of Scotland gave him the palm over Hume, and added: "On the arena of metaphysics Jonathan Edwards stood the highest of all his contemporaries. The American divine affords, perhaps, the most wondrous example in modern times of one who stood gifted both in natural and in spiritual discernment." Sir James Mackintosh says: "This remarkable man, the metaphysician of America, was formed among the Calvinists of New England. His power of subtile argument, perhaps unmatched, certainly unsurpassed among men, was joined with a character which raised his piety to fervor. That most extraordinary man in a metaphysical age or country would certainly have been deemed as much the boast of America as his great countryman, Franklin." Robert Hall's testimony is: "Jonathan Edwards ranks with the brightest luminaries of the Christian church, not excluding any country or any age." Dugald Stewart says: "One metaphysician of America, in logical acuteness and subtilty, does not yield to any disputant bred in the universities of Europe." He was an only son, with 10 sisters, 4 of whom were older than himself. His own father and his mother's father were eminent ministers; he sprung directly from John Warham, the west of England minister who reached America a week or two before Winthrop, settled first in Dorchester, and then with a part of his flock removed to Windsor. The father of young Edwards was distinguished in his day for his knowledge of Hebrew, Greek, and Latin; his mother was a woman of an excellent mind, well cultivated, fond of reading, and of ardent piety. He was trained by his father and his elder sisters for college and to habits of careful study and analysis. The community in which he lived was "remarkably favored by revivals of religion;" and before he was 10 he was much "concerned for his soul's salvation," abounded in religious duties, prayed five times a day in secret, joined with some of his schoolmates to build a booth in a sequestered spot for prayer, and himself had retiring places of his own among the woods. But the boy did not obtain peace of mind; his childhood was troubled "with many exercising thoughts and inward struggles;" and the doctrine of God's sovereignty in choosing whom he would to eternal life and rejecting whom he pleased, used to appear to him like a horrible doctrine. At 10 years old he wrote a paper ridiculing the idea that the soul is material. At 12 he described in a letter to an absent sister "a very remarkable outpouring of the spirit of God" in his native place. "It still continues," he says, "but I have reason to think it is in some measure diminished; yet I hope not much. Three have joined the church

since you last heard; five now stand propounded for admission; and I think above 30 persons come commonly a Mondays to converse with father about the condition of their souls." To the power of analysis, Edwards, like "the great master of those who know," *il maestro di color che sanno*, added the power of observation; and when 12 years old, he sent to a European correspondent of his father an account "of the wondrous way of the working of the spider" in the forest, whose habits he had watched, as it seemingly "tacked its almost imperceptible web to the vault of the heavens," and, swayed by the west wind, moved through the air toward the ocean. With proper opportunities he would like Aristotle have become a great natural philosopher. In Sept. 1716, he entered Yale college. His fellow collegians, only 30 in number, dwelt not together, but scattered in clusters among several villages; Edwards for the most part at Wethersfield. He gained a good name for "his carriage and his learning;" but in his scanty opportunities the range of his learning was very limited. He knew little of classic literature; the best impulse to his mind was given by Locke's "Essay on the Human Understanding," which he read with "a far higher pleasure than the most greedy miser finds, when gathering up handfuls of silver and gold from some newly discovered treasure." But he was quickened, not subdued or mastered, by Locke's system, of which the perusal only roused his own faculties to speculative activity and creative reflection. His nature was inclined to that system which in Europe had found its representatives in Malebranche and Leibnitz; and in some way or other, probably from citations, something of Plato's theory of ideas, and something of the doctrine of Cudworth's "Intellectual System," infused themselves into his youthful reflections. At this early period, when about 15, he, in opposition to Locke, denied the possibility of adding to matter the property of thought; and held that "every thing did exist from all eternity in uncreated idea;" that "spirit or mind is consciousness and what is included in consciousness;" that "truth is the agreement of our ideas with the ideas of God;" that "nothing has a proper being but spirit;" that "matter is merely ideal;" that "the objects of the external senses are but the shadows of being;" that "the universe exists nowhere but in the divine mind." His speculations have sometimes a startling resemblance to those of Spinoza. The latter names thought and extension as the attributes of God, and ascribes being to God alone; Edwards, the collegian, to whom God was Intelligence itself, wrote also that "space is God." In one of his latest works he says of God: "He is all and alone;" "the infinite, universal, all-comprehending entity." In his youth, at 15 or 16, he said: "God and real existence are the same; God is, and there is none else." Spinoza retained till he was past 40 the so-called Arminian theory of the will, and did not adopt that which harmonizes

with Calvinism till he had separated from the school of Descartes. Voltaire in his early manhood taught Madame du Châtelet the Arminian view, though after 40 years of further experience and reflection he asserted the other theory, confessing candidly of himself: "The ignorant philosopher who thus reasons now, has not always been of this way of thinking." But Edwards, while a collegian of 15 or 16, argued out for himself his theory of the will; and his theory of virtue was also fully formed and declared and written down in words. One thing more was wanting to shape his course. He counted himself still among the unregenerate; but after an illness in his last year in college, when not yet 17, how or by what means he could never tell, "his past convictions" were overcome, and he had no more doubts of "God's absolute sovereignty and justice with respect to salvation and damnation." Now he had found the purpose of his life; his speculative opinions and his religious faith were unalterably formed. He had no less than Locke a disposition to show the harmony between reason and religion, the faculties of man and the dogmas of the true faith; but from the first he repelled the materialist philosophy; and while he never came forward as the express combatant of Locke, it became from his early youth the object of his earthly career to combat the results of Locke's philosophy in its application to the sources of knowledge, the science of morals, and theology. From this moment God's absolute sovereignty became to him a delightful conviction; the doctrine exceedingly pleasant and bright. As he read of the King eternal, immortal, and invisible, a new sense of the glory of the Divine Being was diffused through his soul. He longed to be rapt up to him in heaven. He read and meditated on the beauty and excellency of the person of Christ and the loveliness of salvation by his free grace in the soul. In a calm abstraction from the concerns of this world, he yearned to be in the mountains far from mankind, conversing with Christ. His sense of divine things would often of a sudden kindle up "a sweet burning in his heart." He gave an account of his experience to his father, and became a member of the visible church. Now, as he walked in a solitary place in his father's pasture, he saw the glorious majesty and grace of God in conjunction; gentle majesty, majestic meekness; a high and great and holy gentleness. To him "the appearance of every thing was altered; there was, as it were, a calm, sweet cast or appearance of divine glory in almost every thing. God's excellency, his wisdom, his purity and love, seemed to appear in the sun, moon, and stars; in the clouds and blue sky; in the grass, flowers, trees; in the water and in all nature." He often used to sit and gaze at the moon for a long time; and in the day spent much time in viewing the clouds and sky, to behold in them the sweet glory of God; singing forth with a low voice his contemplations of the Creator and Redeemer. He would

watch the thunderstorm, and while thus engaged, or when walking alone in solitary places for converse with God, it always seemed natural for him to chant forth his meditations, or to speak his thoughts in soliloquies with a singing voice. He was satisfied of his good estate, but he longed so vehemently for more holiness, that his soul was breaking for its longing. Prayer was as natural to him as the breath which relieved his inward burnings. With soul-animating and refreshing delight, he saw the divine excellence of the things of God, and tasted their soul-satisfying and life-giving good.—For two years after he took his degree he remained in New Haven as a student for the ministry; and in Aug. 1722, before he was 19 years of age, he was selected to uphold, as a preacher, the cause of Calvinism in a Presbyterian church in the city of New York. Here he remained 8 months, increasing all the time in his sense of divine things. Heaven appeared to him as a world of love; holiness as ravishingly lovely—a divine beauty, of a charming serene nature, bringing purity, brightness, and peace. He would retire into a solitary place on the banks of the Hudson river for contemplation of divine things, hanging a thought on every thorn. Life in the commercial city enlarged his sympathies, and on the arrival of a ship "his soul eagerly caught at any news favorable to the interest and advancement of Christ's kingdom." Here, on Jan. 12, 1723, he made anew a solemn dedication of himself to God. He remained in New York long enough to learn to love the place "where he had none other than sweet and pleasant days;" and when, in April, 1723, he returned home, his parting hour "was most bitter;" his heart seemed to sink within him, and as he sailed away he kept sight of the city as long as he could. At his father's house in East Windsor he continued his severe and unremitting studies, made with the pen in hand. Here, too, he finished a series of 70 resolutions, most of which he wrote in New York. He humbly entreated God by his grace to enable him to keep them all; to act always for the glory of God, for the good of mankind in general; to lose not one moment of time; to live with all his might while he did live; to let the knowledge of the failings of others only promote shame in himself; to solve as far as he could any theorem in divinity he might think of; to trace actions back to their original source; to be firmly faithful to his trust; to live as he would if it were but an hour before he should hear the last trump; to strive every week for a higher and yet higher exercise of grace; "to keep a benign aspect, and to let there be something of benevolence in all his speech." Abounding in spiritual and holy joys, the young "seraphic doctor" of Congregationalism cherished no hope like that of the exercise of holiness and "a burning love to God." It was also a comfort to him to think of that state of fulness of joy where reigns heavenly, calm, and delightful love. "How sweetly," said he, "will mutual lovers

join together to sing the praises of God and the Lamb." He heard of the wondrous virtues of a child of about 14, and noted them down in this wise: "They say there is a young lady in New Haven who is beloved of that Great Being who made and rules the world, and that there are certain seasons in which this Great Being in some way or other comes to her and fills her mind with exceeding sweet delight, and that she hardly cares for any thing, except to meditate on him; that she expects after a while to be received up where he is, to be raised up out of the world and caught up into heaven; being assured that he loves her too well to let her remain at a distance from him always. There she is to dwell with him and to be ravished with his love and delight for ever. Therefore, if you present all the world before her, with the richest of its treasures, she disregards it, and cares not for it, and is unmindful of any path of affliction. She has a singular purity in her affections; is most just and conscientious in all her conduct, and you could not persuade her to do any thing wrong or sinful if you would give her all this world, lest she should offend this Great Being. She is of a wonderful sweetness, calmness, and universal benevolence, especially after this Great God has manifested himself to her mind. She will sometimes go about from place to place, singing sweetly, and seems to be always full of joy and pleasure, and no one knows for what. She loves to be alone, walking in the fields and groves, and seems to have some one invisible always conversing with her." This young lady was Sarah Pierrepont, daughter of a minister, and like Jonathan Edwards having ministers for her ancestors, among them Thomas Hooker, one of the best of men; one who filled his earthly career with great deeds, and left a free and imperishable commonwealth as his monument. In Sept. 1723, having received at New Haven his degree of master of arts, several congregations invited Edwards to be their minister; but he declined every proposal, reserving 2 years more for study. In June, 1724, he entered on the office of tutor in Yale college; and he and his colleagues are remembered as "its pillar-tutors and glory;" all the while practising ascetic abstinence, not of food only, but of sleep, for the sake of closer diligence. In the summer of 1726 he received an urgent invitation to become the pastor of Northampton, as the colleague of his grandfather, Solomon Stoddard; and on Feb. 15, 1727, in the 24th year of his age, he was introduced to his office. Every omen promised usefulness, honor, and happiness. His residence was in the most beautiful town of New England, where no one can live without imbibing love for the place. The inhabitants were all, even those who were mechanics, engaged in agriculture. The rich soil teemed with abundance; the people were none of them wealthy, but all enjoyed plenty, and the community was affluent. The scenery is as cheerful as it is beautiful, propitious to mental serenity, and there was scarcely another village

possessed of so much intellectual culture. It was the shire town of a very large county; the most populous, richest, and happiest town in western Massachusetts. Hardly was the young divine settled with a competent salary, than the thought of Sarah Pierrepont joined itself with his studies and his devotions. "Patience," said he to her in one of his love letters, pleading for an immediate union, "patience is commonly esteemed a virtue, but in this case I think I may almost regard it as a vice." She listened to his urgency, and on July 28, about 5 months after he was settled, the youthful preacher was joined in wedlock at New Haven with the wonderfully endowed bride of his choice. She was pure and kind, and uncommonly beautiful and affectionate, and notable as a housekeeper; he holy, and learned, and eloquent, and undoubtedly the ablest young preacher of his time; she 17, he 23. What was wanting to their happiness? The union continued for more than 30 years; and she bore him 3 sons and 8 daughters. In Feb. 1729, the senior pastor died at the good age of 85, and the young minister of 26 was left with the sole care of the town. Notwithstanding a weakly and infirm constitution, his zeal and industry were equal to every duty. His wife spared no pains to conform to his inclinations, and ministered cheerfully to his comfort, as her greatest glory and best service to God and her generation. She was a good manager; and he carried into the business of life the same thorough exactness which marked his researches. Yet he kept himself as free as possible from worldly cares, giving himself wholly to the work of the ministry; rose early, and employed himself in study all day long. He made no visits unless sent for by the sick or the sorrowing; but encouraged persons under religious impressions to come to consult him on the state of their souls, and they were sure of easy access and tenderness. The little exercise which he took consisted in solitary walking or in rides on horseback among the lonely woods; but his mind was in full action all the time he was abroad, and he would return richly laden with thoughts. His fame spread more and more widely. In July, 1731, he was prevailed upon, notwithstanding "his youth and modesty," to preach the Thursday lecture in Boston; and "divers ministers" found him to be a workman that need not be ashamed before his brethren; printed his sermon; approved his teaching "evangelical principles to the churches notwithstanding all their degeneracies;" and "heartily rejoiced in the special favor of Providence in bestowing such a rich gift on the happy church of Northampton." He gradually obtained universally the character of a good preacher, beyond any one of his times; writing out his thoughts with care, but uttering himself fluently and freely, in words full of ideas, without regard to his notes; above all, adding to his close reasoning and great acquaintance with divinity an inward sense of true experimental religion. His own experience and his rare powers of observation

gave him great insight into the human heart, and he knew what was in man, both in saint and sinner. His voice, though not strong, was clear and distinct; and his manner, though he used little of gesture, discovered his own fervor and effectually moved the hearts of his hearers. He often had sweet complacency in God and in the excellency of Jesus Christ. The holiness of God appeared to him the most lovely of all the divine attributes. God's absolute sovereignty and free grace, and man's absolute dependence on the operations of God's holy spirit, appeared to him more and more as sweet and glorious doctrines. He loved to adore him as a sovereign, and ask sovereign mercy of him; it seemed "that it would spoil heaven to receive it in any other way." Thus he taught his people the doctrines of the gospel, which were to his soul and theirs like green pastures. He himself in his humility was "as a little white flower, which may be seen in the meadows in the spring of the year, low and humble on the ground, opening its bosom to receive the pleasant beams of the sun's glory; rejoicing as it were in a calm rapture; diffusing around a sweet fragranc; standing peacefully and lovingly in the midst of other flowers round about, all in like manner opening their bosoms to drink in the light of the sun." To this New England Christian philosopher the village meeting house was the porch of the Academy, and plain country people the pupils who clung to him for views of spiritual glory. What teacher in his widest fame was greater than he? How poor in the comparison was Leibnitz, speaking to the old dowager electress of Hanover, or to the queen of Prussia, or to Prince Eugene! How did the gospel preacher, who declared divine truth, not indeed to the learned, but to the universal heart, rise in dignity above Massillon, pleasing the licentious court of Louis XV. with his beautiful diction; or even Butler, instructing Queen Caroline to fulfil all her parts and bless all her children! Is it strange that Edwards should have thought often of the millennium, or that it should have come into his mind that that happy period was to take its beginning in New England? Edwards shunned always mere speculative questions; but the Arminian doctrine, which made man's regeneration his own work, was regarded by him as of the most dangerous practical tendency. He held mind to be above matter; "the works of God in the conversion of one soul to be a more glorious work of God than the creation of the whole material universe;" and he saw no end to the immoral consequences of that human pride which would claim this greatest work as its own. "The doctrine of men's being the determining causes of their own virtue teaches them not to do so much as even the proud Pharisee did when he thanked God for making him to differ from other men in virtue." Against this pride he opened a war in 1734, begun by discourses on justification by faith alone. His assiduity and power were followed by a wonderful revival

of religion; his predecessor had had five harvests, but the harvest of this year and the next exceeded every thing that had been known at any time in any part of the country. It was on this occasion that Edwards printed a sermon on "A Divine and Supernatural Light imparted to the Soul by the Spirit of God;" a performance imbued with his views of the source of knowledge as well as of the regenerating influence of the Spirit. He wrote a narrative of these surprising conversions, which was printed in England, and republished in Boston with some doctrinal discourses against the Arminians. In all his reading, the pleasantest thing to him had ever been to read of the advancement of Christ's kingdom, and his mind was entertained with the Scripture prophecies. In 1737, as he rode in the woods on the Connecticut river, and alighted to walk for divine contemplation and prayer, he had an extraordinary view of the glory of the Son of God, and his full, pure, and sweet grace and love, which kept him for an hour in a flood of tears, weeping aloud. On a Saturday night in Jan. 1739, he perceived so clearly how blessed a thing it is to walk in the way of duty, that it caused him to break forth into loud weeping; for he had an affecting sense how meet and suitable it was that God should govern the world and order all things according to his own pleasure, and he rejoiced in it that God reigned and that his will was done. The fruit of this excitement of mind was, two months after, in March, 1739, the beginning of a volume of discourses on universal history, treating the wonderful series of successive acts and events as the record of God's redeeming providence from the beginning—a conception not less sublime and more full of feeling than that of Bossuet in his "Universal History"—but failing in the execution alike from deficiency and from excess, the want of close knowledge of events, and the disposition to construct out of interpretations of prophecies a narrative also of the future, even to that perfect state of things settled for eternity. In this way years rolled over the eloquent messenger of celestial truth, and he was thoroughly happy. His wife also had the deepest religious experience, as though a glow of divine love came down from the heart of Christ in heaven into her heart in a constant stream, like a pencil of sweet light. A very great revival began to extend far and wide through the New England colonies, a subject of interest and instruction to the world, having, as many think, a permanent influence on the character of the people, fitting them for the great events in their history that were soon to come. Tradition still keeps in memory the wonderful effect of Edwards's sermon at Enfield on sinners in the hands of an angry God. He wrote "Thoughts on the Revival of Religion;" and, after long meditation, he, in 1746, gave to the world his "Treatise concerning Religious Affections," a work full of his spirit, permeated by all his cherished doctrines on morals, and marked by keen analysis of states of mind, which showed his self-possession in the

midst of the most exciting scenes. No one has better analyzed and described the affections of the human mind under religious influences; and though his style in this work is neither polished, nor concise, nor correct, his characterizations of counterfeit piety are sometimes worthy of the pen of a La Bruyère or a Rochefoucauld. His house was always the home of hospitality. In 1747 he invited the missionary Brainerd, whose life was wasting away with a hectic fever, to come under his roof; and with the exception of a short visit to Boston to consult physicians, Brainerd remained with him, nursed and cared for and comforted, till his death. Meantime war raged between France and England; Edwards's parishioners took an eminent part in the capture of Louisburg in 1745; and it happened in the next year that the night after a day of fasting and prayer, appointed for the colony, and kept most fervently at Northampton, the terrible French "armada," under the duke d'Anville, was finally dispersed, and utterly confounded; "the nearest parallel," said Edwards in his plea for a visible union of God's people in extraordinary prayer, "the nearest parallel with God's wonderful works of old in Moses's, Joshua's, and Hezekiah's time, of any that have been in these latter ages of the world." This trust in Providence never failed him; but his life was now destined to meet with seemingly one of the saddest of afflictions. The New England of that day appeared to grudge a home to its noblest sons, as though resolved that they should elsewhere find their shelter. One of the two greatest had felt himself, while yet a boy, forced to run away; and the other, the Dante of the New England churches, as Osgood of New York rightly calls him, was destined to be driven into exile. The civil tribunals take cognizance of offences against the law; the ecclesiastical courts of the Catholic church exercised a supervision over the inmost actions of the soul. Among the Puritans that power of the keys was taken from ecclesiastical courts, bishops, and priests, and transferred to the several bodies of covenanted believers. The members of each New England visible church exercised a brotherly superintendence over one another, and dealt with those offences of mind or heart of which the laws of the land took no notice. Edwards discerned levities of manner, consequent as it seemed on reading books which a severe morality could not approve, and he invoked the attention of his church to the subject. The church disapproved of the scandal which would follow an inquiry, and let the matter fall to the ground. Here then it appeared that there was some deeper defect; the church, under the lax discipline of Stoddard, had been filled up with persons who, though outwardly well behaved, were not saints by calling. The Catholic church offered bread to the people, the cup only to the consecrated; the reformation established the equality of all believers, and the Lutherans and the Anglican church offered bread

and wine alike to all. Calvin and the Congregationalists offered both to every one who partook of either, but confined them both to visible believers, the regenerate, the elect; and baptized only the children of communicants. On this latter system were the churches of Massachusetts and Connecticut originally founded; but the Catholic church from the beginning, and the Lutheran and the Anglican for centuries, had baptized all children born within their pale; and the influence of their example, prevailing more and more after time had enfeebled the passion for dissent, made the New England people generally desire to secure the ordinance of baptism for their offspring. Half-way covenants, and an opening of the church doors to the unregenerate, was the consequence. The half-way system was illogical and superficial, and there was nothing half-way about Edwards. According to the Catholic church, the eucharist was changed into the body and blood of Christ himself; the Lutherans held Christ to be present with and under the elements; but Calvinists held Christ to be present only in the soul of the believer, and therefore there was no place at the Lord's table for the unregenerate, for those who could not ascend in spirit into the presence of Christ in heaven. As the seal of a covenant, the sacrament presupposes conversion. Edwards desired to enforce the rule, which in the Northampton church had been evaded, not abrogated; and the pure-minded, sincere, logical, consistent pastor found himself at variance with a church of seemingly visible Christians, who made no profession of that in which real Christianity was admitted to consist. The pastor would have sanctifying grace go before admission to full communion; the brethren were of opinion that the Lord's supper is a converting ordinance. A Congregational minister is only the moderator of his church; Edwards was overborne by the majority. He proposed to deliver a course of lectures on the subject, and they refused him their consent. After years of difference of opinion, the greatest man in the New England churches was, on June 22, 1750, driven away from his congregation, to which he had devoted the 24 best years of his life; and now, as his decline was beginning, with a wife and 10 living children, of whom but one was provided for by marriage, he was left without any visible means of support. He must quit the scenes that he loved; the groves in which he had meditated; the modest mansion where he had studied; the elm trees which his own hands had planted. Throughout the whole controversy, it is hard to say which was most admirable, the single-hearted humility of Edwards, or his martyr-like firmness; and when afterward he gave an account of his ejection, he candidly revised his own conduct, and sought to find cause of blame in himself. When the news reached Scotland, his friends there invited him to come over and establish himself in that country; Samuel Davies of Virginia, the same who uttered the famous prophecy about

Washington, entreated him to remove to Virginia, offering to surrender to him his own parish, and pleading that he and he only had weight enough by his representations in Great Britain to stop the illiberal oppression of Presbyterians by the governors of the Old Dominion. But neither Scotland nor Virginia could offer him a certain provision; and the man whose intellectual endowments were unequalled in the land, had no option but to accept a small offer from the agent of the London society for propagating the gospel to become a missionary to the remnant of Housatonnuck Indians at Stockbridge. The handful of white settlers that had gathered round the tribe also asked him to become their pastor. The trifling income thus obtained was slightly improved by the delicate handiwork of his wife and daughters, which was forwarded to Boston to be sold. It was apparently hard that so wise and great a man should have so limited a sphere of duty; but in truth his sphere was enlarged by his removal, and now embraced the whole English world. A mind like his yearned for intimate intercourse with its kind; at Northampton, Edwards was the centre of a wide circle of influence, visited by many guests, consulted by many churches; at Stockbridge, all his preaching to the Indians was uttered extempore, without notes, aided by an interpreter; and when he was once established in a house of his own, he found himself possessed of more leisure for study than he had ever before enjoyed. The next 6 years of his life were years of uninterrupted study. The narrow apartment that formed his work-room found him early, all the day, and late at his desk; he scarcely shared the meals of his family, except to ask Heaven's blessing on them; and it is the tradition, that while his wife and the children continued at their repast, Edwards would retire to his pursuits, coming out only to return thanks when they had done. The development of the views which had long engaged and swallowed up his mind, formed the chief entertainment and delight of his life. He was happy in these employments. His method of study had ever been by writing; applying himself to improve each important hint, and penning down his best thoughts on innumerable subjects, for his own benefit. But now in his absolute retirement, like a father of the church in the wilderness, his thought was for his fellow men in the world, and his sense of duty cheered him on to undertake for his country and the world a refutation of opinions which, as he believed, were false in themselves, though they were brought forward with an air of triumph as the achievement of superior liberality and discernment. The main point in the discussion between Arminians and Calvinists first engaged him. The topic had been carefully considered by him from the time he was 15 years old, and he had kept minutes of his thoughts during the intervening period; it was therefore with a perfect mastery of the subject that he made it his first object in his seclusion to finish and bring before the

world an "Inquiry into the Freedom of the Will." This, written out in a very short period of time, not exceeding 5 months, was published in 1754. While he was engaged in preparation for this work, Aaron Burr, the president of the college of New Jersey, at Princeton, after a three days' personal acquaintance at Stockbridge, married Edwards's third daughter. Distressed and enfeebled by a half year's illness, his partial recovery only sent him into new fields, and he completed a dissertation on "God's Last End in the Creation of the World," which is a picture of his own character, reasoning, and mind. He also wrote a dissertation on the "Nature of True Virtue," in which he embodied the convictions that he had formed in youth, and had carried with him through life, as the very centre and heart of his religious experience and his philosophical reflections. One essay more belongs to this period, in which he touched none but the highest and most momentous subjects; it is the discourse on "Original Sin." But the more he accomplished the more he longed to accomplish, and he took upon his mind and his heart what he himself saw was to be "a great work:" Christian theology in the form of a history; a revision and completion of the history of redemption which he had written at Northampton; a history to be carried on with regard to all three worlds, heaven, earth, and hell. The plan of other treatises crowded also upon his active mind. These studies were interrupted by the death of his son-in-law, the president of Princeton college, and for his successor the trustees of that institution looked to the wilds on the frontier of Massachusetts. They called Edwards from his task of teaching the Housatonnucks to take charge of the central seminary of the country. After some hesitation he consented to accept the invitation, repaired to Princeton, kindled by his presence and his words the liveliest interest among the students, and on Feb. 16, 1758, was installed as president. The small pox was prevailing in the neighborhood; as an act of precaution he was inoculated, took the disease under a malignant form, and had only to prepare to die. To his wife, who was absent, he sent his kindest love; recalled the uncommon union which had so long subsisted between them, and trusted that as their union had been spiritual in its nature, it would continue for ever. "Trust in God, and ye need not fear," were his last words; and then, 34 days after his installation as president, at the early age of 54, all of him that was mortal calmly and without a struggle fell asleep. He was buried at Princeton with every tribute that reverence for his genius and piety could offer. His wife was not long divided from him; his daughter soon joined her husband, who had preceded them all; so that in a week and a year the 4 graves of Edwards, his wife, his son-in-law, and his daughter, were added to the burial place of Princeton.—In considering the writings of Jonathan Edwards, the first thing to be borne in mind is his childlike,

sincere, unquestioning acceptance of the truth of every word in the Holy Scriptures, of every event recorded there, of every miracle and every prophecy; the actual fall of man, the incarnation, death, resurrection, and ascension of Christ. The next is, the intensity of his attachment to the system of Calvinism as opposed to that of Arminianism; he declares it himself everywhere; if in any thing he departed from its essential principles, it was done without his consciousness, and therefore, according to every rule of interpretation, his words are never to be forced into an antagonism to the reformed confessions of faith. These points being premised, the characteristics of all that Edwards has written are threefold. He looks always to establish the reasonableness of his views. The doctrine of a divine incarnation, for example, approves itself, as he thought, to human reason; and he cites in proof of this the authority of Greeks and Romans, the most philosophical nations of the world. He even refers to the *anima mundi* of Blount and the pantheism of Spinoza. He scoffs at the pretensions of greater liberality put forward by the Arminians, and puts reason and common sense on the side of orthodoxy. In this battle, he was in Europe preceded by Leibnitz, with whose works he was not acquainted, and was followed by Lessing and Kant, who were at all times ready to defend the sternest doctrines of orthodoxy, election, free grace, and eternal punishment, and especially the Trinity. "There is," says he, "no need that the strict philosophic truth should be at all concealed from men, no danger in contemplation and profound discovery in these things. The truth is extremely needful to be known; and the more clearly and perfectly the real fact is known, and the more constantly it is kept in view, the better. The clear and full knowledge of that which is the true system of the universe will greatly establish the doctrines which teach the true Christian scheme of divine administration in the city of God." Least of all would Edwards give up the individual right of free inquiry, for he says: "He who believes principles because our forefathers affirm them, makes idols of them; and it would be no humility, but baseness of spirit, for us to judge ourselves incapable of examining principles which have been handed down to us." In harmony with this principle, and indeed as a necessary consequence of it, his teachings all bear the marks of universality. He knows no scheme of Christianity that is the fruit of time; the Logos took counsel with the Father; the divine administration of which he desired to unfold the character began from eternity and reached forward to eternity. The third great characteristic of his mind is its practical character. His system has in view life and action; he puts aside all merely speculative questions, and while he discusses the greatest topics that can engage the mind of man, he never treats them but because of his overwhelming consciousness of their important bearing on conduct and morals. He never involves himself in sublapsarian or supralapsarian subtleties; he

never proposes as a problem the contradictory question, if willingness to be damned must precede hope of salvation; he moves in the real world among his fellow men, and brings theology down from the dim clouds of speculation to the business and the bosoms of the universal people.—It is one of the strangest misconceptions that has ever been uttered about Edwards, that he drew his philosophy from Locke. In the dismal want of books, the essay of Locke was the work which trained him to philosophical meditation; but his system was at its foundation, as well as in every part of its superstructure, the very opposite of the theory of Locke.—On the subject of the origin of ideas, the views of Edwards accord with those of Leibnitz, which in the present day have been in some measure popularized by Cousin. The doctrine that all truth is derived from sensation and reflection he discards as "a low, miserable notion of spiritual sense." "A clear apprehension of things spiritual" he calls by the name of "light," and attributes it not to "the external senses," not to "the inferior powers," but to "a new principle," "the divine nature in the soul." "It is some excellent communication from the divine beauty and glory." "It is the Spirit of God that gives faith in him," were the words of his sermon at the Boston lecture in 1731; and 3 years later he enforced at large that it is a doctrine of reason, that "a divine supernatural light is immediately imparted to the soul by the Spirit of God." There and elsewhere he teaches that knowledge of spiritual truth cannot be derived from "second causes," from the senses, from flesh and blood; that it is a wisdom not earthly or sensual or natural, but descending from above; that it is "nearly related to a participation of the Deity;" that it is "a kind of emanation of God's beauty;" that "it is the image and participation of God's own knowledge of himself;" that "it is beyond man's power to obtain this knowledge and light by the mere strength of natural reason," and by natural reason he means the understanding as it deals with knowledge acquired through the senses; in a word, that "to see spiritual things depends on the sense of the heart." The term is not well chosen; but by sense of the heart he means what later philosophers mean by intuitive reason; and by "spiritual understanding," that higher faculty which reaches at truth which is not received by the senses, "and could be produced by no exalting, varying, or compounding of that kind of perceptions or sensations which the mind had before." In like manner he finds the idea of causality "implanted by God in the minds of all mankind." And generally, "there is an infinite fountain of light and knowledge, and light shines forth in beams of communicated knowledge." "The Spirit bears witness with our spirits." "There is some new sensation or perception of the mind;" "a new simple idea." As a consequence, the contrast of Edwards with Locke and those who came after him appears

equally in the different manner in which they sought to establish the truth of Christianity. The disciples of Locke's philosophy cling to the historical evidence from miracles as the principal proof of the truth of the Christian religion. Not so Edwards. There have been "lying miracles," and Satan can impress the mind with outward representations; therefore Edwards laid down the principle broadly: "No particular sort of outward representations can be any evidence of a divine power." He scorned to make history the proof of Christianity; for thus men might be "very much of an opinion that it was true," but not have "knowledge" of its truth. "Unless men may come to a reasonable, solid persuasion and conviction of the truth of the gospel, by the internal evidences of it, by a sight of its glory, it is impossible that those who are illiterate and unacquainted with history should have any thorough and effectual conviction of it at all. To have a conviction, clear and evident and assuring, the evidence they can have from history cannot be sufficient, but endless doubts and scruples will remain. If men who have been brought up in heathenism must wait for a clear and certain conviction of the truth of Christianity until they have learning and acquaintance with the histories of politer nations enough to see clearly the force of such kind of arguments, it will make the evidence of the gospel among them immensely cumbersome, and will render the propagation of the gospel among them infinitely difficult. It is unreasonable to suppose that God has provided for his people no more than probable evidences of the truth of the gospel. It is reasonable to suppose that God would give the greatest evidence of those things which are greatest, and the truth of which is of the greatest importance to us. But it is certain that such an assurance is not to be attained, by the greater part of them who live under the gospel, by arguments fetched from ancient traditions, histories, and monuments. There is not the least reason to suppose that one in an hundred of those who have been sincere Christians, and have had a heart to sell all for Christ, have come by their conviction of the truth of the gospel this way. Many of them lived and died in times wherein those arguments for the truth of Christianity from antiquity and history had been but very imperfectly handled. And indeed it is but very lately that these arguments have been set in a clear and convincing light, even by learned men themselves. And since it has been done, there never were fewer thorough believers among those who have been educated in the true religion; infidelity never prevailed so much in any age as in this, wherein these arguments are handled to the greatest advantage. The true martyrs, as the very name of martyrs or witnesses implies, are witnesses who can and do testify that they have seen the truth of the thing they assert, having had the eyes of their minds enlightened to see divinity in the gospel, or to behold that unparalleled, ineffably excel-

lent, and truly divine glory shining in it, which is altogether distinguishing, evidential, and convincing. So that they may truly be said to have seen God in it, and to have seen that it is indeed divine; and so can speak in the style of witnesses. The gospel of the blessed God does not go abroad a begging for its evidence so much as some think; it has its highest and most proper evidence in itself."—The theory of Edwards respecting providence corresponded with that of Leibnitz, and varied from that of the school of Locke, which Leibnitz so pointedly condemned. To Edwards the laws of nature were not established and left to themselves, but were the methods according to which God continued his "immediate influence." "God does by his immediate power uphold every created substance in being." "Their existence in each successive moment is the effect of his immediate agency, will, and power." "His preserving created things in being is equivalent to a continued creation."—To express the intensity of his faith in the absolute sovereignty of God, Edwards never could find words of sufficient force. Not Calvin himself could adopt the doctrine more completely and unreservedly. The presence of moral evil, the depravity of human nature, he considered from two points of view. He raised his mind to the contemplation of God as the Creator, and had then no theory to offer for man's depravity but the divine will. He never presumed to ask Almighty God why it was so. To him it was an ultimate fact, the evident act of infinite power; he never undertook to arraign God at the bar of human reason, and plead before men for a verdict of acquittal for the Almighty. But to those who questioned this absolute sovereignty, and rejected it as a doctrine full of horror, he made a twofold answer, not as finding excuses for the Creator, but subjectively as shutting the mouth of cavillers: first, that man's depravity is an unquestionable fact; that through the medium of his senses and merely animal organization man can attain to no knowledge of God and no spiritual perfection; and those who cannot solve the difficulty must get over it by acknowledging the weakness and scantiness of their understandings. Secondly, Edwards also set forth the unity of the race; its common constitution as branches from one root, forming one complex person, one moral whole: "Adam and his posterity were one;" which is also the view of Augustine and Calvin, the faithful interpreters of Paul of Tarsus. This view also had a most important bearing on the theory of morals.—The momentous question of man's relation to moral evil, and the way of his escape from it, formed one of the chief objects of Edwards's thoughts during his whole life. "Men in a very proper sense may be said to have power to abstain from sin, because it depends on the will;" and if they will not, the defect is in themselves. A man's evil disposition may be as strong and immovable as the bars of a castle. The law of causality extends to every

action. Liberty consists in the power of doing what one wills; and the power of willing belongs to the man or the soul. The cause of an action is complex. The volition follows the greatest seeming good; and what shall seem to a man the greatest good depends on the state of his soul. Liberty is to be sought for, not in the act, but in the man; and if a depraved nature is to abstain from sin, it can only be effected by a change of heart. This theory Edwards asserted by an appeal to the facts of universal experience, and by a most thorough, complete, and unanswerable analysis of the complex cause of action. All the while that he was engaged in this most severe demonstration, the seemingly stern doctrine appeared to him as involving man's dignity and worth, and his abstruse reasoning was answered by a flood of perfect melody in his heart.—From the consideration of the will, the transition is natural to the theory of virtue; and Edwards finds it to consist in love—not in love as resting complacently on its objects, but in love as the ruling motive of the will; love in action, benevolence. A knowledge of divine things comes from the divine in man; as justification comes of faith, so virtue has its perennial spring within the soul. And this love is not for self; the doctrine of Edwards is the intensest protest against the theory of self-love. He raises the soul to the highest point of contemplation, takes it as it were to be present at creation, and bids it love actively all that is, universal being, the all-comprehending entity of God; so that the virtuous man, with holy love sanctifying his will, is sent forth joyously for action, action, and still for action, as God's own soldier and servant. Thus virtue includes right reason, holiest love, and action; a rational motive, warmed by love, and bearing fruits of righteousness. The view is not an eccentric one in Edwards's system; it lies at its heart. It appears in his college manuscripts; it colors a half dozen of the resolutions which he formed at 20; it runs through his treatise on the affections; it reappears in his essay on the end of God in creation. It must be accepted, or Edwards himself cannot be accepted. It enters too deeply into all that he has written to be set aside as no essential part of him, and must be explained and developed in connection with the sum of all his doctrines. The test of a theory is that it embraces and absorbs all that is good and true in other theories on the same subject; the rod of the true prophet swallows up all the rods of his opposers. Does virtue imply the love of God with all the soul? This is exactly the doctrine of Edwards; for God is the Being of beings, "in effect, Being in general." Does it consist in respect for the moral fitness of things? That moral fitness lies impressed on the universe which perfect moral power has created. Does it consist in the avoiding extremes? The universe of being is moderated by the divine law, and is ever giving the lesson of just order and proportion. Does it consist in regard to truth? And where

is truth to be found but in the world that God created, and in the Being of beings himself? Does it rest on sympathy? But nothing so certainly and universally commands sympathy as a spirit that is in harmony with the whole system of God's providence. The love to universal Being includes all being, each in its degree, according to its amount of existence; active love for the good of the world of mankind before the love of country, of country before that of a single city, of a city before a family, of the family before the individual, of the individual only in subordination to the great system of the whole. The theory is directly at war with the system of self-love as the foundation of moral order, or a respect to happiness as the only good; for where self-love is made the root, it grows to be inordinate, and is at war with the being of the whole. But every man, into whatever career of enterprise he goes, may take Edwards along with him in all his course of prosperity, if he will but seek that alone which is in harmony with the greatest good, and keep every passion and inclination subordinate to the divine will. Least of all would Edwards, whose whole theory is one of love, weaken the bonds of family affection; only the love of wife or husband, parent or child, must not be the paramount motive; the wife must cheer her husband to do his duty, even though he is called upon to become a martyr; the father may bless his son, who goes forth to battle for his country's freedom, or as a missionary defies the danger of foreign climes to diffuse the knowledge of pure religion. On Edwards himself the effect of this theory is apparent in a wonderful tenderness toward every thing, a compassion for human frailties, a candor of judgment that mirrored the purity of his soul. Viewed in this light, the doctrine of the oneness of the race, which Edwards asserted with greater clearness and force than the modern school of philosophers who have so much to say of the *solidarité* of humanity, gains new significance, as may be seen, not altogether without excesses, in the writings of his followers.—The ethical theory of Edwards is cosmical; no one was ever more so. His manner of contemplating the universe was also cosmical. It embraced more than the whole course of time, and all as one work; universal history resting on the principle of the redemption of the world, decreed from all eternity; a history of the gradual progress and advancement of the race through the presence of the Divine Word and its ever approaching triumph over all its enemies. Events seem confused like the work of an architect, who employs many hands in many kinds of labor at once; but a knowledge of the design removes all appearance of confusion; and so the design of the Divine Word in redemption gives unity to the history of all the nations of the earth. The development of this idea employed the latest thoughts of Edwards. He left his work unfinished; but the sketch shows how completely he considered universal history as the record of God's providence, and the cen-

turies as a progressive series; tumults and revolutions following one another from age to age, only to bring forth truth and holiness, so "that all things should be shaken until that comes which is true and right, and agreeable to the mind of God, which cannot be shaken," and victory be brought to pass by "a gradual progress," "very swiftly, yet gradually." Every error of opinion and superstition must be abolished. "Well may we admire," says Edwards, "the greatness of this building of God, which he builds up age after age." "All the revolutions in the world are the sum of God's works of providence." "The work of the new creation is more excellent than the old; so it ever is: when one thing is removed by God to make way for another, the new excels the old." "The events of providence seen in this light appear an orderly series of events, wisely directed in excellent harmony and consistence, tending all to one end. The wheels of providence are not turned round by blind chance, but they are full of eyes round about, as Ezekiel represents, and they are guided by the Spirit of God; where the Spirit goes they go; and all God's works of providence through all ages meet in one at last, as so many lines meet in one centre. It is with God's work of providence as it is with his work of creation: it is but one work—one regular scheme. There are many stones, many pieces of timber, but all are so joined and fitly framed together that they make but one building; they have all but one foundation, and are united at last in one top stone. God's providence may not unfitly be compared to a large and long river having innumerable branches, beginning in different regions, and at a great distance one from another, and all conspiring to one common issue."—The sum of the whole is that Edwards makes a turning point in the intellectual, or, as he perhaps would have called it, the spiritual history of New England. Calvin had risen up to battle against mediæval superstitions and mediæval aristocracies; a plebeian, or to use his own word, "*homunculus*," introducing thorough republican reform; for outward penance substituting purity of heart; for hierarchy and laity, the equality of believers. Setting himself up over against the privileged classes, he, with a loftier pride than theirs, revealed the power of a yet higher order of nobility, not of a registered ancestry of 15 generations, but one absolutely spotless in its escutcheon, pre-ordained in the council chamber of eternity. But here in the forests of America there was no danger of exile, imprisonment, and fire; there were no persecutions to defy, no oppressive authority to combat. The time was come when two other of the original component elements of Calvinism should receive their development. The faith condensed in the symbols of Calvinism demanded to be subjected to free inquiry, and, without "dodging, shuffling, hiding, or turning the back," to be shown to be in harmony with reason and common sense. Predestination ceased to be the doctrine that best

nourished the spirit of patriotism and liberty; and in the free, peaceful, and happy homes of the New England yeomanry, it yielded the justly due precedence to that principle of active "love, which is the comprehension of all true virtue." The great representative of this period of transition is Jonathan Edwards. New England and New Jersey, in the age following Edwards, applied more thought to the subject of religious philosophy and systematic theology than the same amount of population in any other part of the world; and his influence is discernible on every leading mind. Bellamy and Hopkins were his pupils; Dwight was his expositor; Smalley, Emmons, and many others were his followers; through Hopkins his influence reached Kirkland, and assisted to mould the character of Channing. Edwards sums up the old theology of New England, and is the fountain head of the new. The toils of a century turned the wilderness, to which men had been driven for liberty to say their prayers, into a garden of plenty, peace, and joyous activity; he that will trace the corresponding transition of Calvinism from a haughty self-assertion of the doctrine of election against the pride of oppression to its adoption of love as the central point of its view of creation and the duty of the created; he that will know the workings of the mind of New England in the middle of the last century, and the throbbings of its heart, must give his days and nights to the study of Jonathan Edwards.—There are several lives of Jonathan Edwards; the most interesting is that by Hopkins, who was his pupil; the fullest is that by Sereno Edwards Dwight. There have been two editions of his works in England, one in 8 vols. 8vo. and one in 2 compact volumes. The American editions are to be preferred. One was published at Worcester, Mass., edited by Samuel Austin, in 1809, in 8 volumes. The New York edition is by Sereno E. Dwight, in 10 vols. 8vo., of which the first contains the life. There is also a later and convenient New York stereotype edition in 4 volumes, of which there have been numerous impressions.

EDWARDS, JONATHAN, D.D., president of Union college, Schenectady, son of the preceding, and like him distinguished as a metaphysician and theologian, born in Northampton, Mass., May 26, 1745, died in Schenectady, N. Y., Aug. 1, 1801. At the age of 6 years he went with the family of his parents to Stockbridge, where there was but one school, and that common to the children of both the Indians and white inhabitants, of the latter of whom there were so few that he was in danger of forgetting the English tongue. He so thoroughly learned the language of the Stockbridge Indians, that, as he tells us, all his thoughts ran in their dialect; and though its pronunciation was extremely difficult, the natives acknowledged that he had acquired it perfectly, which, they said, had never before been done by any Anglo-American. This knowledge of their language he retained through life, and in later years pub-

lished his celebrated treatise on the subject, which led Humboldt to say that if he had not been the greatest theologian, he would have been the greatest philologist of his age. In his 10th year he was sent by his father, with the Rev. Gideon Hawley, among the Six Nations, that he might also learn their language, and become qualified to be a missionary among them. Here he made rapid progress, and became a general favorite; but owing to the disturbances of the French war, he remained but a few months, when he returned to Stockbridge. In 1761 he entered the college at Princeton, N. J., where he was graduated in 1765. After leaving college he studied divinity with Dr. Bellamy, and in 1776 was licensed as a preacher of the gospel. In 1767 he was appointed tutor in the college at Princeton, and soon after accepting this office, which he held 2 years, was chosen to the professorship of languages and logic, which he declined. In 1769 he was ordained as pastor of the church in White Haven, in the town of New Haven, Conn., where he continued till May 19, 1795. Resigning this charge, mainly on account of difference in doctrinal views between himself and some of his people, he was settled in 1796 as pastor of the church in Colebrook, where, in addition to professional duties, his time was devoted to his favorite studies, and to an extensive correspondence which he had long carried on with learned men both in this country and in Europe. In May, 1799, he was elected president of Union college, and entering on the duties of this office, he gave himself with unwearied diligence to the instruction of the students, and to all that might advance the prosperity of the institution, for the 2 remaining years of his life. There were several remarkable coincidences in the lives of Dr. Edwards and his father. They were similar in character and structure of mind. Both were early distinguished for their love of study, and were tutors for equal periods in the colleges where they were respectively educated. Both, after having been settled in the ministry, were dismissed on account of their doctrinal opinions, and were again settled in retired places, where they had leisure to prepare and publish their valuable works. Both were called from these situations to be presidents of colleges, and both died, shortly after their respective inaugurations, one in the 55th and the other in the 57th year of his age, each having preached on the first Sabbath of the year from the text: "This year thou shalt die." Dr. Edwards was a man of great acuteness, strength, and comprehensiveness of intellect, and profoundly skilled in the philosophy of the human mind. His complete works, edited with a memoir of his life by his grandson, the Rev. Tryon Edwards, D.D., were published in 2 vols. at Andover in 1842.—JONATHAN W., a lawyer, the only son of the preceding, born in New Haven, Conn., Jan. 5, 1772, died in Hartford, April 3, 1831. He was graduated at Yale college at the age of 17, and was afterward tutor in the same institution. On taking

his second degree, he delivered an oration, in which he attacked the existing law by which the eldest son received a double portion of the estate of the father, if the latter died intestate. This excited so much attention throughout the state, that at the next meeting of the legislature the obnoxious law was repealed. Having studied law at Litchfield, he settled at Hartford, where he rose rapidly in his profession, and soon became widely known as a profound lawyer and distinguished advocate. Unremitting application to his profession so impaired his health that he early retired from public life.—TRYON, D.D., an American clergyman and author, son of the preceding, great-grandson of the first and grandson of the second President Edwards, born in Hartford, Conn., Aug. 7, 1809. He was graduated at Yale college in 1828, and after studying law in New York, and theology at Princeton, settled in the ministry at Rochester, N. Y., in 1834. He removed his pastoral relations in 1845 to New London, Conn., his present residence. In 1832 a prize tract on Sabbath schools appeared from his pen, and he has from that time contributed constantly and in various forms to the religious press. Among his publications are an address delivered at Williams college in 1841, entitled "Christianity a Philosophy of Principles;" a memoir of the younger President Edwards, published with his complete works (1842); "Self-Cultivation" (1843); and a memoir of Dr. Bellamy, published with his complete works (1850). He has edited, beside the works of the younger President Edwards, a volume entitled "Charity and its Fruits," from the MSS. of the elder President Edwards, and several collections designed especially for domestic culture, as "Select Poetry for Children and Youth" (1851); "Jewels for the Household" (1852); the "World's Laconics" (1852); and "Wonders of the World" (1855). Several of these books have passed through many editions, and have been republished in England. Dr. Edwards has been a frequent contributor to the "Christian Spectator," "New Englander," "Biblical Repertory," "Biblical Repository," and other periodicals of note, and was for many years editor of the "Family Christian Almanac."

EDWARDS, JUSTIN, D.D., an American clergyman, born in Westhampton, Mass., April 25, 1787, died at Virginia Springs, July 23, 1853. He was graduated at Williams college in 1810, settled in the ministry at Andover in 1812, removed thence to the Salem street church, Boston, in 1828, and in 1829 resigned this charge to become secretary of the American temperance society, in the service of which he was engaged for 7 years, presenting its cause with great ability and success, by lectures and addresses, in every part of the land, and preparing the well-known "Temperance Documents." After this, he was for 6 years president of the Andover theological seminary, and then for 7 years engaged in promoting the observance of the Sabbath, writing the "Sabbath Manual" &c. He then spent 4 years in pre-

paring a brief commentary on all the New and part of the Old Testament, for the American tract society, before finishing which he was called from his earthly labors. Dr. Edwards was the author of several valuable tracts on moral and religious subjects, some of which have had a wide circulation. Of his "Temperance Manual," some 200,000, and of the different parts of his "Sabbath Manual," about 1,500,000 copies have been published. A memoir of his life and labors, by the Rev. Dr. Hallock, was published by the American tract society in 1855.

EDWARDS, MILNE. See MILNE-EDWARDS.

EDWARDS, RICHARD, one of the earliest English dramatists, born in Somersetshire in 1523, died in 1566. He was educated at Corpus Christi college, Oxford, where he obtained distinction for scholarship, and became under Elizabeth one of the gentlemen of the queen's chapel, and had charge with others of the theatrical representations before the children there. His "Damon and Pythias" was the first English tragedy on a classical subject, and was acted before the queen at Oxford in 1566. Though he was esteemed among the best writers of interludes and rude comedies of the time, all his other dramas are lost. He wrote several minor poems, one of which, entitled *Amantium Iræ*, has been often reprinted in modern collections.

EDWIN, king of Northumbria, born in 586, ascended the throne in 617, died in 633. He was but 3 years old when at the death of his father the throne was usurped by Edilfrid, and he himself was placed by his friends under the protection of Cadvan of North Wales. The British prince was assailed by the Northumbrian, and the two armies met in the vicinity of Chester. Victory decided for Edilfrid, and a body of monks who had stationed themselves on a neighboring hill to deprecate the success of the invader were put to the sword, and the great monastery of Bangor, containing 2,100 monks, was demolished. Edwin then wandered through the different principalities of the Britons and Saxons, till he found an asylum at the court of Redwald, king of the East Angles. Redwald made war on Edilfrid; the armies met in 617 on the banks of the Idel, in Nottinghamshire; Edilfrid was defeated and slain, and Edwin without further opposition ascended the throne. The martial genius of Edwin raised Northumbria to preëminence among the Anglo-Saxon states. The islands of Anglesea and Man became subject to his authority, all the princes of the Britons paid him tribute, and among the Saxon kings Eadbald of Kent alone retained a nominal independence. So inflexible was his administration of justice, that in his days it was a common saying that a woman or child might openly carry everywhere a purse of gold without danger of robbery. The chief event of his reign was the introduction of Christianity into the kingdom of Northumbria. He married Edilberga, a princess of Kent, daughter of that

Bertha by whose influence the king and people of Kent had been already converted to Christianity. Yet neither the entreaties of the young queen, the arguments of the learned bishop Paulinus, nor the letters and presents of Pope Boniface V., could for a long time turn him from the worship of his fathers. He consulted alternately the priests on either side, revolved in solitude their opposite arguments, assembled the witenagemote for consultation, was strongly influenced by his many successes, which Paulinus ascribed to the favor of Christ, and at last avowed himself a convert, and was followed by his people. Edwin perished in a disastrous battle with the combined armies of Penda, king of Mercia, and Ceadwalla, king of the Britons, who had raised the standard of rebellion, and marched into Yorkshire. Previous to this reign the northern metropolitan of the Anglo-Saxon church had been directed to fix his residence at York, and Paulinus, who held this office, received from the king a house and other possessions in that city.

EDWY, surnamed the Fair, a king of the Anglo-Saxons, son of Edmund I., and successor of Edred, born about 938, ascended the throne in 955, died in 959. He was of a passionate character, and according to the monks, who are the only historians of his reign, of dissolute manners. Having on the day of his coronation retired from the banquet to the apartment of a young princess named Elgiva, he was violently taken back to the table by St. Dunstan. The affront was one not to be forgiven, and Dunstan was banished from the kingdom. Archbishop Odo, however, broke with an armed force into the villa where Elgiva resided, defaced the beauty of that lady with brands, and exiled her to Ireland. She subsequently returned to England, where she suffered hamstringing and died. It is in dispute among historians whether Elgiva, who was within the prohibited degrees of consanguinity, was the wife or mistress of Edwy. The English favored the ecclesiastics rather than the king, and a rebellion broke out under Edgar, a younger brother of Edwy, who was chosen king by the Mercians. Edwy was obliged to flee beyond the Thames, and the civil war was ended in 957 by a general meeting of the thanes, who determined that that river should be a boundary between the dominions of the two brothers. Edwy governed his portion, which consisted of Wessex and Kent, in peace and to the satisfaction of his subjects till his death.

EECKHOUT, or ECKHOUT, GERBRANT VAN DEN, a Dutch painter, born in Amsterdam, Aug. 19, 1621, died there, July 22, 1674. He was one of the pupils of Rembrandt, and in some measure successful in imitating his manner, especially in the early part of his life. He excelled chiefly in painting portraits, and these as well as his historical pictures abound in the best collections of Holland, while several of them are to be found in Germany. His most esteemed work represents Christ among the doctors.

EECLOO, or **Eccloo**, a town of Belgium, in the province of East Flanders, 11 m. from Ghent; pop. in 1856, 8,837. It has an active industry and commerce in woollen fabrics, hats, tobacco, and oil, and is the most important grain market in the province.

EEL, a name applied to several malacopterous fishes of the families *anguillidae*, *congeridae*, and *murænidae*, especially to the typical genera *anguilla* (Cuv.), *conger* (Cuv.), and *muræna* (Thunb.). From their snake-like appearance, and the absence of ventral fins or posterior limbs, they have been called anguiform *apodes*; they all have the body more or less elongated and cylindrical, no ribs in the skeleton, a cæcal stomach, and simple not-jointed fin rays. In the genus *anguilla*, to which the common eel belongs, the scarcely apparent scales are cycloid, narrow, oblong, arranged in groups at right angles to each other, forming a kind of lattice-work under the cuticle; the whole skin is soft and slimy, thickly studded with muciparous glands and ducts; the nostrils are double, each having 2 orifices, the anterior prolonged into a tube, and the posterior opening above the mouth; the teeth are card-like or villiform in both jaws, and a few on the anterior part of the vomer; the gill-opening on each side is very small, and just in front of the pectoral fin, which exists in all the species; the dorsal fin begins at a considerable distance from the head, and behind the pectorals, and forms a continuous fin with the caudal and anal; the lower jaw is longer than the upper. There are about 50 species described. The common eel of the northern and middle states (*A. Bostoniensis*, Lesueur, and *vulgaris*, Mitch.) is greenish or olive-brown above, and yellowish or yellowish white beneath, often with a reddish tinge along the anal fin; in a specimen 2 feet long, measured by Dr. Storer, the short pectorals were about 8 inches from the end of the snout. The eel inhabits both salt and fresh water, from the British provinces to the southern states, wherever it can find its favorite muddy bottoms and extensive flats; it prefers shallows near the shore, where it may be caught in great numbers by hook and line, by bobbing, and by spearing; the places frequented by it are called eel grounds, in which during the winter the fishes bed themselves in the soft mud to the depth of about a foot, and are then speared through holes cut in the ice; the best time for catching them is at night, by torch-light. During their passage up and down rivers they are taken in baskets and pots baited by fish or any decaying matter. The eel is very voracious and quite omnivorous; when in good condition it is a well-flavored fish, though, from its snake-like appearance (and it is only in form that it resembles a snake), most persons are prejudiced against it. The length varies from 6 inches to 2½ feet; in summer it is sometimes seen weighing several pounds. At the mouths of the rivers emptying into Boston harbor eels are caught in nets, 15 or 20 bushels at a time, and are kept

alive until wanted for market in ditches supplied by the tide. In Feb. 1858, at Harwich and the neighboring towns on Cape Cod, the principal part of the male population were engaged in eeling; the fish were obtained by spearing through the ice; in a single bay, and on one day, 200 men speared 100 bushels, or 1,200 dozen; such as were not consumed in the town were sent, packed in ice, to Boston, New York, and other cities, where they were readily sold. The silvery eel (*A. argentea*, Les.) is silvery gray, darker above, and satiny white below; the pectorals are nearer the head than in the common species, of which, however, it is considered by some only a variety; it is taken in pots in October, when it leaves the ponds. A large species, caught in the lakes of western New York, is the beaked eel (*A. rostrata*, Les.); the snout is elongated and pointed; the upper parts are olive-gray, sometimes slaty blue, and the lower parts white; the dorsal and anal fins reddish; length about 2 feet. The common eel of Europe (*A. acutirostris*, Yarrell) has a sharper snout than ours; it is highly esteemed as an article of food, and the London market is supplied principally from Holland, from which the eels are brought alive in vessels carrying each from 15,000 to 20,000 lbs. Eels are much esteemed in other countries, especially, according to Ellis, in Polynesia, where they are often tamed and fed until they attain an enormous size. The attention of fish breeders might be very profitably directed to this family; they are numerous, prolific, hardy, easily preserved in salt, fresh, and brackish water, and will always find a ready sale. Eels are described as making 2 migrations annually, one in autumn to the sea, the other in spring or summer from the sea to the rivers. They are not found in arctic regions, nor in the rivers of the extreme north of Europe; even in temperate regions, at the approach of winter, they bury themselves in the mud, remaining torpid until spring; they remain without food, breathing hardly at all, at a low animal temperature, and almost motionless; yet the irritability of the muscular fibre is very great, as is shown by the restless motions of eels during thunder storms, and by their well-known movements after the skin has been removed. Though not possessing the respiratory pouches of the anabas (see **ANABAS SCANDENS**), the eel is able to survive a long time out of water, simply because the gills remain moist from the small size of the branchial orifices; by this means it traverses considerable distances on land, moving like a snake through the grass; in this way is explained the appearance of eels in fish ponds from which the utmost care has been taken to exclude them, on account of their destruction of the spawn and young of more valuable fishes; they have been often seen performing such overland journeys at night. Eels are found in fresh water which has no communication with the sea; having a capacious air bladder, they are able to ascend rapidly to the surface, and sometimes swim very high in deep

water; though slow of growth, they attain a large size under favorable circumstances, having been caught in England weighing 27 lbs. The town of Ely is said to have been so named from the rents having been formerly paid in eels, the lords of the manor being annually entitled to more than 100,000; Elmore, on the Severn, was so called from the immense number of these fish there taken.—The conger eels differ from the genus *anguilla* in having the dorsal fin begin nearer the head, at or even in front of the pectorals, and in having the upper jaw the longer; the anterior nostrils open by short tubes close to the end of the snout, and the posterior in front of the large eyes; the teeth of the palate and vomer are slender, with chisel-shaped crowns, and closely arranged; the skin is naked and scaleless, and the tail elongated and pointed; in other respects they resemble the common eel. The American conger (*conger occidentalis*, De Kay) is olive-brown above and whitish below; the dorsal and anal fins are transparent with a dark border; the lateral line is distinct, with a series of white dots; it grows to a large size, from 3 to 5 feet in length, and either this or another species is found from the gulf of St. Lawrence southward as far as the coast of New Jersey. The European conger (*C. vulgaris*, Cuv.) is common on the coast of Cornwall, on the eastern rocky shores, and in banks off the coast of France; it is caught on lines, the best bait being the sand lance (*ammodytes*) or the pilchard, and the fishing is performed at night; great numbers are taken, and meet with a ready sale at a low price to the poorer classes, but it is not held in much estimation. Congers are very voracious, and acquire a large size; specimens have been caught weighing 180 lbs., more than 10 feet long, and 18 inches in circumference; they are very strong, bite sharply, and have great tenacity of life. As many as 156 vertebræ have been found in the conger, about 40 more than are found in the eel; they spawn in December and January. Sir John Richardson alludes to 9 species.—The eel of the Mediterranean, so famous in the days of ancient Rome, belongs to the genus *muræna*, characterized by the absence of pectorals, smooth and scaleless skin, small lateral branchial orifice on each side, and the united dorsal and anal fins, low and fleshy, hardly distinguishable beyond the margin of the body; the teeth are arranged in a single row around the edge of the nasal bone, with a few on the longitudinal median line. More than 20 species are described, attaining the size of 4 or 5 feet; one (*M. moringa*, Cuv.) was found by Catesby at the Bahama islands. The classic species of the Mediterranean (*M. Helena*, Linn.), the Roman *muræna*, grows to the length of 4 or 5 feet; the color is a purplish brown, marked with sub-angular yellow markings, and spotted with beautiful shades of yellow, purple, golden yellow, and white; the anterior nostrils open near the end of the snout, the posterior just above the eyes; the cheeks are rather tumid from muscular development.

It has been caught on the English coast, but it abounds in the Mediterranean; great numbers were consumed by the ancient Romans, who kept them in ponds, and even placed them alive on the table in crystal vessels that the guests might admire their beautiful colors before they were cooked. Cæsar is said to have distributed 6,000 of these fishes among his friends on the celebration of one of his triumphs. They are very voracious and fierce, and are said sometimes to have been fed on the flesh of slaves who had offended their Roman masters. They are fished for with strong lines, and their bite is much dreaded by the fishermen; they are very tenacious of life. The flesh is white, delicate, and much esteemed. There are many species, exclusively marine.—The sand eel (*ammodytes Americanus*, De Kay) has an elongated, slightly compressed body, large gill-openings, a dorsal fin extending nearly the whole length of the back, and an anal fin of considerable size, both separated from the caudal; the lower jaw the longest; the color is yellowish or bluish brown above, mixed with silvery and light green; the sides and abdomen are silvery; the length is from 6 to 12 inches. This species is found from the coast of Labrador to that of New York; in the provinces it is largely used as bait for cod; it is very common in Long Island sound from May to November, constituting in its season the principal food of the bluefish and bass; it is also eaten by eels, and other fish; the cephalopod cuttle fish preys upon it extensively; like the tropical flying fish, it is pursued by fishes in the water, and by gulls and terns in the air. The names of sand lance and *ammodytes* are given to it from its habit of darting out of and into the sand, head foremost and instantly, by means of its projecting lower jaw. Its food is principally insects. On the coast of England it is esteemed as food, and is raked out of the sand at low tide in great numbers; it is also caught in seines. Two species are described.—ELECTRICAL EEL (*gymnotus electricus*, Linn.). Though apodal and eel-like in general appearance, this fish differs from the eels in the completeness of the jaws, the presence of ribs, and the jointed fin rays; it has neither ventral nor dorsal fin; the anal reaches to the point of the tail, and like the pectorals is enveloped in a thick skin which conceals the rays; the skin is soft and scaleless; the head is oval and flat, the mouth furnished with broad lips, and opening not quite as far as under the eyes; the anterior nostrils are small tubes in a slight depression on the side of the lips, the posterior are behind and above them; lateral line distinct; about 50 pointed teeth on the upper jaw, and 60 on the lower, a second row of about 6 behind the middle of the upper ones, and 4 small teeth in 2 rows along the symphysis; the vent opens before the branchial orifices, and behind it is a small opening and a slender papilla. The only species known inhabits the rivers of the northern parts of South America; it attains a length of 5 or 6 feet, and is of a brown and yellowish color. The elec-

tric apparatus which has rendered this fish so celebrated occupies the space between the pectorals and the tail, for a large part of the lower bulk of the body; the organs are 4 in number, 2 on each side, the upper and larger organ being separated from the lower by a thin stratum of muscle and membrane, and the organs of one side are distinct from those of the other; the apparatus consists of an assemblage of membranous horizontal plates, nearly parallel and intersected by delicate vertical plates; the cells thus formed are filled with a glutinous matter; the septa, according to Hunter, are about $\frac{1}{30}$ of an inch from each other, and one inch in length contains 240 cells, giving a very great surface to the electric organs. The system is abundantly supplied with nerves from the 200 pairs of ventral spinal nerves, but not from the lateral continuation of the trigeminus and vagus nerves from which the electric system of the torpedo is supplied. The electric eel seems to be a mere appendage to the anterior part of its battery for purposes of moving it about, as all the other organs are confined to a very small space, even the vent opening under the head; and the nerves supplying the electric organs are much larger than those sent to any sensory or motor organs. According to Humboldt, the South American Indians capture these eels by driving horses and mules into the water inhabited by them; the electric powers of the fish being exhausted on the quadrupeds, the former are harpooned and thrown on shore; the horses suffer greatly, many of them being killed by the electric discharges of the fish which glide beneath their bodies. By grasping the head of the eel with one hand and the tail with the other, the most painful and almost insupportable shocks were received, in the experiments of Faraday. This fish is neither voracious nor fierce, but uses its battery to secure its prey, and to defend itself from its numerous enemies. (See ELECTRIC FISHES.)

EELEE, ELE, or ILI, also GOOLDJA, GOULDJA, or GULDSCHA (Chinese, *Hoei-yuan-tching*), a city of S. W. Soongaria, China, and capital of a district of its own name; pop. 75,000. It is a place of banishment for Chinese criminals, but has also considerable trade with the cities of the province of Kansoo, and with other parts of the empire. It is well fortified, surrounded by walls of stone, and contains barracks for the troops, granaries, and government offices. It is situated on the right bank of the river Eelee, a stream over 800 m. long, which rises in the mountains of Thian-shan-nan-loo, and empties into Lake Tengheez or Balkash, near the borders of Siberia.

EELS, EELKEYATS, or ILIYATS, a name applied to the wandering tribes of Persia. They are found in every part of the country, and although many of them have become inhabitants of cities and villages, the majority preserve their ancient customs, living in tents and disclaiming all connection with the old Persian stock. In winter they keep to the plains, but on the approach of summer ascend to the

mountains, where they find abundant pasturage for the flocks and herds which constitute their only wealth. They breed camels, horses, and sheep. The latter furnish them with milk, which is made into liquid butter and sold to the inhabitants of the lower country. They pay tribute to the government, and are obliged to furnish a certain number of soldiers and horsemen for the Persian army. In personal appearance the Eeleeyats are frequently prepossessing. The men are hardy, powerful, and well proportioned, with dark brown skins, aquiline noses, and piercing black eyes. The women when young are often beautiful, having delicate nut-brown complexions, regular features, handsome teeth, and countenances beaming with good humor. But perhaps no women in the world change so completely as they advance in years. With the approach of old age the charms of the Eeleeyat females vanish; their skins parch and wither, and their pleasing expression gives place to one of inconceivable repulsiveness. The Eeleeyats usually dwell in communities of 20 or 80 families. Lady Sheil, in her "Glimpses of Life and Manners in Persia" (London, 1856), remarks that "the tent-dwelling Eel is to be recognized by his bold and manly air and his free and independent look. The stationary Eels are termed either Tats or Takhteh Kapoo; the latter term implies that their doors are made of wood, that is, they live in houses. They are also termed Dehnisheen, which means village dwellers."

EESSAH, SOMAULEE, or SOMAULI, a powerful tribe inhabiting the territory of Adel, on the coast of the sea of Babelmandeb, E. Africa. They are a pastoral people, leading a roving life, and subsisting chiefly on the produce of their flocks and herds. They have no fixed habitations, and wear little other clothing than a leather apron. They carry shields, spears, bows, and poisoned arrows. The Danakils, a neighboring tribe, hold them in great dread, and describe them as a nation of thieves and murderers, but the character given them by European travellers is more favorable.

EFFEN, JUSTUS VAN, a Dutch scholar, born in Utrecht in 1684, died in Bois-le-Duc, Sept. 18, 1785. He was a graduate of the university of Leyden, and for many years was a private teacher, conducting at the same time several literary periodicals. His first publication of this kind was called *Le misanthrope*, written in French and published at the Hague, shortly after the appearance of Addison's "Spectator." This was succeeded by the *Hollandsche Spectator* (1781-'35). He spent some time in England as secretary of the Dutch embassy, and translated "Robinson Crusoe," Swift's "Tale of a Tub," and 146 numbers of the "Guardian," into French. So thoroughly was he master of that tongue, that some of his writings which appeared anonymously were at first attributed to Fontenelle. A collection of his French works appeared at Amsterdam in 1742, in 5 vols. A 2d edition of his *Hollandsche Spectator* was published in the same city in 1756.

EFFENDI (Romaic, *αρετής*, lord), in Turkey, the title given to civil officers, learned men, and all those who fulfil any important function.

EFFERVESCECE, the action which takes place, resembling boiling, when a gas is copiously evolved in the breaking up of one chemical compound and the formation of another, as when the acid and alkaline powders of effervescing draughts are dissolved or mixed, or when an acid is dropped upon carbonate of lime. In both instances carbonic acid gas escapes, as it is said, with effervescence.

EFFERVESCENT POWDERS, preparations of acid and alkaline powders, put up in differently colored papers in order to distinguish them, to be used as a medicine by mixing the contents of two different papers after these have been dissolved, and drinking while the chemical reaction is taking place with effervescence. The common soda and Seidlitz powders form effervescing draughts, the acid in one of the papers combining with the alkali of the carbonate in the other, and expelling the carbonic acid. This gas, continuing to be evolved in the stomach, acts as a refrigerant and diaphoretic, while the alkaline salt is slightly laxative. The drink is especially adapted to febrile complaints from its cooling and refreshing qualities. The common soda powders consist of 25 grains of tartaric acid in one paper, and 30 grains of bicarbonate of soda in the other. An equivalent proportion of bicarbonate of potash is sometimes substituted for the soda. The following are the proportions given in the "American Dispensatory": tartaric acid 1 oz., bicarbonate of soda 1 oz. and 54 grains, or bicarbonate of potassa 1 oz. and 160 grains. The acid and either bicarbonate, being separately reduced to fine powder, are divided each into 16 portions. Citric acid is sometimes employed instead of the tartaric acid, in the proportion of 9 drachms to 11 of the soda salt, or 13 of the potash. Seidlitz powders are a mixture of 2 drachms of Rochelle salts (tartrate of potash and soda) and 2 scruples of bicarbonate of soda in one paper, and 35 grains of tartaric acid in the other. The tartaric acid being in excess renders the medicine more pleasant to take, without interfering with its aperient quality.

EFFIGY, HANGING IN, a mode of execution recognized in the ancient legislation of Franch, in the case of a criminal condemned to death, but who had escaped from custody. In default of the person, a likeness of the convict was conveyed to prison after judgment had been pronounced; whence, at the appointed time, it was taken by the executioner, and conveyed with all the usual solemn and ignominious ceremonies to the public scaffold, and there fastened by the neck to the gallows. Thus, in the reign of Louis the Fat, in the 12th century, Thomas de Marle was hanged in effigy for high treason; and under Louis XIV., in 1662, Alexandre de Noirmoutiers was punished in the same manner for the part which he took in a famous duel. The legislation of the first French republic modified this old custom, suppressing the imitation

of an execution, and reducing the ceremony to merely posting the name of the condemned person, together with the judgment against him, upon a public place. The execution by effigy has existed down to the latest date in many other countries, being exercised both by governments and, without legal sanction, by the people. In England it is a popular method of venting spite against unpopular men. Thus in London it was long a custom to hang Guy Fawkes in effigy annually, and frequently the most prominent men of England incur this penalty for some political or ecclesiastical offence.

EFFINGHAM. I. An E. co. of Ga., bounded W. by the Ogeechee river, and separated from South Carolina on the E. by the Savannah; area, 480 sq. m.; pop. in 1852, 8,671, of whom 1,675 were slaves. It has a generally level surface, with a sandy unproductive soil, but there are extensive pine and cypress woods, and lumber is an important article of export. In 1850 the productions were 87,794 bushels of Indian corn, 37,252 of sweet potatoes, and 257,901 lbs. of rice. There were 21 churches, and 208 pupils attending public schools. The county was named in honor of Lord Effingham, a British officer who resigned his commission rather than take arms against the American colonies. Capital, Springfield. Value of real estate in 1856, \$526,703. II. A central co. of Ill., drained by Little Wabash river, an excellent mill stream; area, about 500 sq. m.; pop. in 1855, 6,226. It has a level surface, occupied by woodlands and fertile prairies in almost equal proportions. Copper, lead, and iron are found here, and the chief agricultural productions are grain and wool. In 1850 the county yielded 227,025 bushels of Indian corn, 5,169 of wheat, 36,028 of oats, 7,105 lbs. of wool, 41,671 of butter, and 341 tons of hay. There were 5 churches, and 526 pupils attending public schools. Capital, Ewington.

EFFLORESCENCE (Lat. *effloresco*, to flower), the crumbling to powder of some saline bodies as they part with the water that enters into their composition. This is observed in sulphate of soda or Glauber's salts, and in the carbonate also, and is the opposite of deliquescence, in which moisture is abstracted by the salt from the air. The term is also applied to the shooting out of minute spicular crystals, called sometimes a saline vegetation, such as those of saltpetre seen upon the walls of cellars.

EFT, a name given to several species of newts, especially to the common smooth newt (*liostrotion punctatus*, Daud.). The generic characters of the tritons, or aquatic salamanders, will be given under **NEWT**, which the eft resembles in the slightly free tongue, double longitudinal series of palatal teeth, and nailless toes, 4 before and 5 behind; the skin, however, is smooth, and the dorsal and caudal crests are continuous; there are 2 patches of glandular pores on the head, and none on the back or sides. The newts belong to the genus *molge* of Merrem, and *triton* of Laurenti. Bell separated

the efts in the genus *liæotriton*. The color in the male is brownish gray above, passing into yellowish beneath, which in the spring becomes bright orange; there are numerous round dark spots of unequal size, and 2 longitudinal streaks on the head; the crest in spring is often tipped with red or violet. The female is light yellowish brown, or buff with brown dots, plainer below. The total length is about $8\frac{1}{2}$ inches, of which the tail is nearly one half. It is very common in the ditches and ponds of Europe, especially where the water is clear; its food consists principally of aquatic insects, larvæ, worms, and mollusks. The reproduction and metamorphosis are almost identical with those of the newts. Though usually spending most of their time in the water, the young in June, and the adults in summer and autumn, become terrestrial; they appear to attain their full size the first year. The experiments of Spallanzani show that the members and the tail may be reproduced several times in succession, with bones, muscles, vessels, and nerves. Like the other amphibia, it is very tenacious of life, and can resist even congelation. Its bite is perfectly harmless. They are eaten by the larger amphibia, by fishes, and by various reptiles, birds, and small carnivora.

ÉGALITÉ, PHILIPPE. See ORLEANS.

EGBERT, king of Wessex, and 1st king of the united Anglo-Saxons, born about 775, ascended the throne of Wessex in 800, died in 836. The defeated rival of King Brihtric, he took refuge first at the court of Offa, the king of Mercia, and afterward in France, where he was received at the court of Charlemagne, in whose armies he served 3 years. Upon the death of Brihtric in 800 he was recalled to his native country, and acknowledged as king by the West Saxon thanes. In 809 he commenced his career of conquest; and, successively subduing the Britons of Cornwall and the Saxons of Mercia, Kent, Essex, and Northumbria, and assuming at its request the protectorship of East Anglia, by 827 he had become the actual sovereign of the whole heptarchy. In 832 the Danes landed upon the isle of Sheppy, and carried off a rich booty. In 833 they disembarked at Charmonth, and defeated Egbert's forces. They landed again in 835 on the coast of Cornwall, where they formed an alliance with the Britons. Egbert encountered their united forces at Hengstone hill, gained a bloody but decisive victory, punished the rebels, and drove the invaders to their ships. This was his last exploit.

EGEDE, HANS, the apostle of Greenland, born in Norway, Jan. 31, 1686, died in Nov. 1758. After having been several years a pastor in the vicinity of Drontheim, he resigned his functions in 1717, intending to embark for Greenland as a missionary. He was unable to obtain a royal audience before the spring of 1719, owing to the wars with Charles XII. of Sweden, which engrossed the public attention. He then received the patronage of Frederic IV. of Denmark, and set sail in May, 1721, with 2 vessels,

his wife, 2 sons, and 46 other persons, and in July following landed upon the coast of Greenland in lat. 64° N. His mildness and zeal gained the affections of the rude natives, and after several years of effort he was able to preach the gospel in their language. Various calamities, among which were the ravages of the small pox, almost annihilated the result of his labors. Yet before his departure he succeeded in laying a foundation for the further propagation of Christianity upon those icy shores, and in establishing the germs of what was to be an important commerce. The Danish government sent out 3 Moravian brethren to aid him, and after a residence of 15 years in Greenland, Egede, seeing the colony flourishing in the hands of the Moravians, asked and obtained permission to leave it. He continued his labors for the evangelization of Greenland, after his return to Denmark, by publishing several works, and by superintending a seminary designed especially for the education of missionaries for that country.—PAUL, son of the preceding, and successor in his apostolical labors, born at Waagen, near Drontheim, in 1708, died June 3, 1789. He was a child when he went with his father to Greenland, and in 1728 returned, bringing to Copenhagen several Esquimaux, with the design of initiating them into European civilization. They all died, however, of the small pox. After pursuing his theological studies in Denmark, he returned to the mission station, and labored there 4 years after the return of his father. He translated the "Imitation of Christ" and portions of the Bible into the language of Greenland, and at his departure left the colony in a highly prosperous condition. He fulfilled various functions in Denmark, was particularly active in expediting the exploring mission of Lövenön to the coasts of Greenland, and at the time of his death occupied a chair of theology.

EGER (Boh. *Cheb*), a frontier city of Bohemia, on a river of the same name, at the foot of the Fichtelgebirge, 92 m. W. from Prague; pop. 10,500. It has cotton and woollen manufactories, and in its vicinity at Franzensbad are chalybeate springs and baths. Its fortifications, formerly strong, were destroyed in 1808. It has a city hall, in which Wallenstein was assassinated, Feb. 25, 1634, and the ruins of a castle in which the friends of Wallenstein were killed. Eger was taken and retaken by both Swedes and imperialists during the 30 years' war. In the Silesian war it was taken by the French under Marshal Saxe in 1742, and again under the marshal de Belleisle in 1745. Prior to 1850 this city was the capital of a district of the same name, whose inhabitants, 80,000 in number, differed in manners, customs, and costume from the neighboring population. Since then, it gives its name to a circle containing 560,000 inhabitants, in which the former district of Eger is comprised.

EGERIA, one of the *Camenæ* or nymphs of Roman mythology, who was believed to have dictated to Numa Pompilius his wise laws, and

to have instructed him respecting the forms of worship which he introduced. It was said that she even became his wife, and that being inconsolable after his death, she was changed into a fountain. She had been worshipped as a rural and prophetic divinity from the earliest periods of Latium, and was invoked as the giver of life by pregnant women. Numa consecrated to her a grove in the environs of Rome, and to strangers visiting that city even now there is pointed out the grotto and fountain of Egeria in the beautiful valley of Caffarella. Upon ancient sculptures this nymph is represented in a costume similar to that of the muses and sibyls, with floating robe, naked feet, dishevelled hair, and in the attitude of writing in a volume which she holds upon her knees.

EGERTON, FRANCIS. See BRIDGEWATER.

EGERTON, THOMAS, baron of Ellesmere and viscount Brackley, lord chancellor of England, born in Doddleston, Cheshire, in 1540, died in London, March 15, 1617. He was educated at Brazenose college, Oxford, and having been called to the bar, by his learning and integrity soon attracted the attention of Queen Elizabeth. He was appointed successively solicitor-general, attorney-general, on which occasion he was knighted, master of the rolls, and in 1596 lord keeper, the queen herself delivering the great seal to him at Greenwich. James I., upon his accession, in recognition of Sir Thomas Egerton's great services, "not only in the administration of justice, but also in council," created him Baron Ellesmere, and appointed him lord high chancellor. He was subsequently elected chancellor of the university of Oxford. In March, 1617, he resigned the great seal, having retained it, as lord keeper and chancellor, for a longer period uninterruptedly than any of his predecessors or successors. Beside his judicial duties, he was frequently employed by Elizabeth and James in the negotiation of treaties, and in other important state affairs. In person, in character, and in the variety and profoundness of his learning, Lord Ellesmere seems to have been equally admirable. His integrity passed into a proverb, and according to Fuller, many persons went to Westminster hall only "to see his venerable gait, and were highly pleased at so acceptable a spectacle."

EGG. Birds and most insects and fishes, and some other animals, are generated from globular-formed bodies called eggs, produced within the mother. These, after being deposited by the parent in favorable situations, and exposed to the proper influences of temperature, &c., undergo a succession of changes, which at last result in a fully developed living creature. (See EMBRYOLOGY.) This, breaking through the outer crust that has confined it, enters upon its new existence. The eggs of the lower orders of animals are collected and held together in great numbers by a viscous membrane, and are called spawn. Those of birds are deposited singly. They consist of a calcareous shell, white or colored, formed almost wholly of carbonate of lime; the other constituents are minute quan-

ties of animal matter, phosphate of lime, carbonate of magnesia, oxide of iron, and sulphur. Lining this hollow shell is a thin and tough membrane, composed principally of albumen. At the larger end of the egg is a space between the outer shell and this membrane, which, very small when the egg is first laid, gradually increases with its age. It is called the *vesicula æris*, and is filled with air, in which the proportion of oxygen is larger than in the atmosphere. This, it is said, is for the respiration of the unhatched chick. Within the membrane is the white of the egg, or the albumen, a viscid liquid, in membranous cells, which encloses the yolk and the real germ of the animal. As this germ left the place of its production in the body of the female, and passed into the egg-discharging canal, the albumen gathered around it in successive layers, a portion in very delicate membranes, called the *chalazæ*, which are attached to the poles of the yolk, and serve to suspend it in such a manner that the smaller and lighter half must always be uppermost. The outer layer of the albumen is less thick and viscid than that next the yolk. Around it the lining membrane and calcareous shell are successively added before the egg is laid. The composition of the albumen is: water, 85 parts; pure albumen, 12; mucus, 2.7; and saline matter, 0.3, including soda with traces of sulphur; or, according to Dr. Thomson, water, 80; albumen, 15.5; mucus, 4.5; ash, 0.475. The yolk, called *vitellus ovi*, is also a glairy fluid, commonly of a yellow color, enclosed in its own membrane, and consists of a great variety of constituents, viz.: water, 41.486; a form of albumen called vitelline, 15.76; margarine and oleine, 21.804; cholesterine, 0.438; oleic and margaric acids, 7.226; phosphoglyceric acid, 1.2; muriate of ammonia, 0.084; chlorides of sodium and potassium and sulphate of potassa, 0.277; phosphates of lime and magnesia, 1.022; animal extracts, 0.4; and 0.553 of coloring matter, traces of iron, lactic acid, &c. Upon one side of the yolk is a round spot, yellowish white, called the *cicatricula*, the germ of the ovum, which by the arrangement of the *chalazæ*, already referred to, is always kept uppermost, and next to the source of heat supplied by the animal in sitting. As this is developed into the foetus, the albumen first furnishes nourishment to it, and when this is consumed more is supplied by the yolk. Eggs of the hen are hatched by being kept at a temperature of 104° for 3 weeks. Their vitality has been retained after they have been exposed to a temperature of 10° F.; and it is a remarkable fact that the freezing point of new-laid eggs is much lower than that of the water and albumen of which they principally consist, and both of which congeal at about the same temperature. Eggs, too, that have been once frozen, or have been long kept, freeze at the point their constituents would seem to require. The specific gravity of new-laid eggs is from 1.08 to 1.09. By keeping they diminish in weight from evaporation of water, and the substitution of air

through the pores of the shell. This diminution has been observed to continue for 2 years; an egg weighing originally $90\frac{7}{8}$ grains being reduced, as remarked by Dr. Thomson, to 363.2 grains. When they have lost so much weight as to float upon water, they are generally unsound. The preventing of this evaporation by covering their surface with a coating of varnish, wax, gum arabic, or lard, checks their putrefaction. It is said that if every new-laid egg was at once rubbed over with sweet butter, it would be a rare thing to see one unsound. The Scotch sometimes drop them in boiling water for 2 minutes, by which the membrane within the shell is partially coagulated and rendered impervious to air. Hens' eggs vary so much in gravity, that it is a wonder they continue to be sold by numbers instead of weight. A dozen of the largest have been found to weigh 24 oz., while the same number of smaller ones of the same stock weighed only $14\frac{1}{2}$ oz. The fair average weight is said to be about $22\frac{1}{2}$ oz. to the dozen. The relative weights of the portions of the egg as given by Dr. Thomson are: shell and membrane, 106.9; albumen, 604.2; yolk, 288.9. About $\frac{1}{4}$ of the entire weight may be regarded as nitrogenous and nutritious matter, a greater proportion than that of meat, which is rated at only from 25 to 28 per cent., while the nutritive portion of the oyster is only about 12 per cent. The white of the egg, from its tendency to coagulate into a hard and indigestible substance, is likely to disagree with the stomach of invalids, when the yolk may prove perfectly harmless. Raw eggs are more wholesome than boiled, or even than those lightly poached, which are very digestible. Eggs become more difficult of digestion by being kept. In medicine the shell is used as an antacid, its animal composition seeming to adapt it better for the stomach than chalk, the mineral form of carbonate of lime. The white is employed for clarifying liquors and sirups, which it accomplishes by entangling the small particles floating in them as it coagulates, and either rising with them to the surface, or sinking to the bottom. An astringent poultice is formed by causing it to coagulate with a piece of alum briskly stirred with it. This, under the name of alum curd, is used as an application to the eye in some forms of ophthalmia. The white is also used as an antidote to corrosive sublimate and salts of copper. The yolk is sometimes given in jaundice, and forms an excellent diet in dyspepsia. It is preferable to the white in making emulsions. The largest sized eggs of which we have any account are some found in 1850 in alluvium in Madagascar. They belong to a bird which it is supposed has recently become extinct, to which M. Saint Hilaire has given the name of *apiornis maximus*. Two of the eggs are preserved in the French academy. One of them measures $18\frac{1}{2}$ inches on its longest diameter, and $8\frac{1}{2}$ inches on the shortest. The thickness of the shell is about $\frac{1}{4}$ of an inch. The capacity of the egg is about $8\frac{1}{2}$ quarts, 6 times that of the ostrich's egg—equal

to 148 hens' eggs, or 50,000 eggs of the humming bird. From some of the bones of the bird which have been preserved, its height is calculated to be about 12 feet.—EGG TRADE. The demand for eggs as an article of diet has given rise to an immense trade in furnishing the supplies required by large cities and thickly populated districts; and by means of railroads and steamboats they can be transported long distances with despatch and safety. From the western states and from the British provinces they are brought in barrels to the seaboard of the United States, those from the provinces being admitted free of duty. In a single day as many as 15,120 have been entered at Boston from Nova Scotia; and in 1852 about 8,000 barrels, containing 84 dozen each, amounting to about 8,000,000 eggs, were shipped from Montreal to the United States; but this amount is probably small compared with the quantities brought from Ohio and the other interior states. In Great Britain the home production is put down at 75,000 tons annually, and the value at \$15,000,000. Beside this, the importations comprised 117,230,600 eggs in 1856, and 126,818,600 in 1857. The imports from France into England amounted in the former year to £244,041; from Belgium, £19,677; from Spain, £11,880; from the channel islands, £1,731; from other parts, £1,143; total, £278,422. Since 1854 the duty on foreign eggs is 8d. per cubic foot of 200 eggs, and only 4d. on those from British possessions. They are packed in crates and boxes, the contents of a single box amounting to 2,500 to 13,000 eggs. The consumption in Paris is also enormous. In 1835 it was estimated by Legrand at 138 per annum for each individual, and in the provinces at double this rate. By the estimate of M. A. Husson in his late work on the *Consommation* of Paris, the number is now about 175 for each person annually, costing about \$1 35, and the whole population thus supplied is rated at 1,000,000. The following table is given of consumption and prices:

Year.	Number.	Av. price per 1,000.
1847.....	120,940,724	57.00 francs
1848.....	106,747,322	48.40 "
1849.....	112,567,782	46.70 "
1850.....	124,597,150	43.98 "
1851.....	129,732,299	42.69 "
1852.....	160,000,000	41.85 "
1853.....	175,000,000

EGG, AUGUSTUS, an English painter, born in London in 1816. He became a contributor to the academy exhibition in 1838, and was elected associate of that institution in 1848. He has produced a great number of pictures illustrative of humorous scenes from Shakespeare, Le Sage, and Walter Scott. In 1857 he was one of the artists connected with the arrangement of the gallery of modern paintings at the Manchester exhibition.

EGG PLANT (*solanum melongena*, Willd.), the popular name of a species of the *solanaceae*, native of N. Africa. The plant grows to the height of about 2 feet, with a prickly stem, and

with large ovate, downy, prickly leaves; flowers of a violet color, of some beauty; fruit, a globose berry, crowding itself out from the downy calyx, which remains until the fruit ripens, and the deep purple color it assumes indicates its perfection. Its size, however, depends considerably upon the richness of the soil and warmth of climate, and in propitious seasons it reaches several pounds' weight. In India and other hot countries it is a favorite article of food, and is much used in the United States. It is generally served up in India with sugar and wine, and is used by the French and Italians in stews and soups. Another smaller species is *S. origerum*, having a white fruit of the size and appearance of a fowl's egg, chiefly cultivated as an ornamental curiosity, and sometimes reared in pots to secure the ripening, as a long season seems requisite at the north. The seeds of the egg plant should be sown on a slight hot-bed in March or early in April, and the plants should be transplanted in the latter part of May, or in June, in rich, warm ground, at the distance of 2½ feet asunder every way. Weeds should be carefully eradicated from among them, the soil frequently loosened with the hoe, and drawn up around the stems. Among the Chinese, *S. Æthiopicum*, having similar fruit, is esteemed for furnishing an ornamental dish on great occasions and on festal days.

EGINHARD, or EINHARD, the secretary, confidential adviser, and biographer of Charlemagne, born in Austrasia (East France), died July 25, 844. He was a pupil of Alcuin, who introduced him at court. He retired, after his royal patron's death, to a country residence near Mühlheim, in the Odenwald, where he devoted himself to literary pursuits. After the death of his wife, who is believed to have been a daughter of Charlemagne, he built a convent at Seligenstadt, in the present grand duchy of Hesse, and entered it as a monk. The sarcophagus in which he and his wife were buried is still shown at the castle of Erbach, and the counts of Erbach claim to be his lineal descendants. The *Vita Caroli Magni*, by Eginhard, is one of the best biographical works of the middle ages. It has been republished by Ideler (Hamburg, 1889), and also in the second volume of Pertz's *Monumenta Germaniæ Historica*. Eginhard's *Annales Regum Francorum*, and a collection of his letters, are likewise of great value to the historian. The popular version of Eginhard's courtship with Charlemagne's daughter has frequently been the subject of poetical and dramatic representation.

EGLANTINE, an old English name for the sweet brier (*rosa rubiginosa*, Linn.), a well-known and delightfully fragrant-leaved rose, growing plentifully in rich pastures and neglected fields. In deep soils and under favorable circumstances it is not uncommon for the old well-established roots to send up vigorous shoots or suckers 8 or 10 feet high, which are covered with harsh, crooked prickles. The flowers,

which are for the most part borne upon the lower branches, are of a beautiful light rosy color, and full of fragrance. The chief perfume of the plant, however, is in the foliage, its leaves being beset with russet-colored glands, which, on being slightly bruised, emit a peculiar scent. The eglantine succeeds well in the garden, if ample room and a deep soil are allowed it, and in such cases it has been known to produce occasionally double flowers. It grows readily from the seeds, and sown in rows the plants have been clipped into shape to form low and ornamental hedge divisions. The species best known in the United States is supposed to be an adventitious one from Europe, and was introduced with a co-species, also fragrant (*R. micrantha*, Smith), having smaller flowers and a different shaped fruit or seed vessel. Both seem to have scarcely extended beyond the seacoast of New England.

EGLINTON AND WINTON, ARCHIBALD WILLIAM MONTGOMERIE, earl of, born in Palermo, Sept. 29, 1812. He is lord lieutenant of Ayrshire, has held on various occasions other local appointments, and was elected in Nov. 1852, lord rector of Glasgow university. From Feb. to Dec. 1852, he was lord lieutenant of Ireland, and to this office he was again appointed, Feb. 25, 1858. He is principally known as a patron of the turf and as an amateur of tournaments. He gave in 1839 a splendid entertainment of the latter kind at Eglinton castle. The duchess of Somerset, then Lady Seymour, was the queen of beauty on that occasion, and Louis Napoleon took a part in the pageant. His first wife died in 1853, and he married, Nov. 3, 1858, Lady Adela Capel, only daughter of the earl of Essex.

EGMONT, LAMORAL, count of, a soldier and statesman of the Netherlands, born in the castle of La Hamaide, in Hainaut, in 1522, executed in Brussels, June 5, 1568. From his mother, the most beautiful Flemish woman of her time, he inherited the dignity of prince of Gavre, but he preferred the more modest title of count of Egmont, which came to him from his father, and which bespoke a lineage as lofty as many sovereigns could boast. Through a line of chivalrous and distinguished ancestors he traced his descent from ancient pagan Frisian kings. By the death of an elder brother he became sole male heir to the titles and estates of a family which was second to none in Flanders in antiquity, wealth, and power. He was in his boyhood a page of the emperor Charles V., and in his 19th year commanded with distinction a troop of light horse in the expedition against Algiers. Returning to his country by way of Corsica, Genoa, and Lorraine, in 1545 he married Sabina of Bavaria, sister of the elector palatine, the emperor and a concourse of the electors and principal nobles of the empire honoring the nuptials by their presence. He was in the following year invested with the order of the golden fleece; in 1553 he attended the emperor during the siege of Metz; in 1554 he was

at the head of the splendid embassy sent to England to solicit for Philip II. of Spain the hand of Mary Tudor; and in 1555 he was a prominent figure in the throng amid which Charles V. transferred to Philip his dominions in the Netherlands. In 1557, when war broke out between Spain and France, he was esteemed one of the 5 principal generals in the Spanish service, and commanded the cavalry in the army which invaded France and invested St. Quentin. The constable Montmorency advanced with a select body of troops to relieve the garrison, but failed to accomplish his purpose. Egmont, at a council of war held in his tent, proposed to cut off the retreat of the French. His eloquence gained the assent of the council to this project, and having detected a feebly guarded defile in the rear of Montmorency, he threw into it a portion of his cavalry before the constable was able to strengthen it; and the main French army on its approach to the post found itself confronted here by Egmont, who assailed it with a brilliant charge at the head of 2,000 horsemen. The French received a total and most disastrous defeat. Of 21,000 troops, all but 6,000 were killed or captured within an hour; more than 80 standards fell into the hands of the victors; and 600 prisoners of noble birth were on the following day presented to Philip in the camp before St. Quentin. Rarely had a Spanish monarch enjoyed so signal a triumph as that which was thus achieved by the promptness and gallantry of Egmont. In the following year the marshal de Thermes, who had taken a distinguished part in the capture of Calais, marched into West Flanders, storming and pillaging Dunkirk and devastating the country as far as Nieuwpoort. Flushed with victory and laden with spoils, his army was already on its homeward march, when Egmont took the field to intercept its retreat. With such forces as he could collect in the neighborhood, amounting to 10,000 foot and 2,000 horse, whose numbers were increased by large volunteer bands of the peasantry, he threw himself into the path of the French army, and arrested its progress near Gravelines. In the hard-fought action which followed, Egmont displayed brilliant valor, and the army of De Thermes was annihilated, and himself taken prisoner. In respect to its results, the battle of Gravelines was one of the most decisive in history, for it compelled the French monarch to consent to a treaty which has been pronounced more ruinous than any other in the annals of France. These two splendid victories gave Egmont great renown and popularity, and largely augmented his hereditary influence in the Netherlands. Rather from a generous sensibility to the wrongs of his countrymen than from any settled principle, he ranked himself among the malcontents against the oppression of Philip, in opposition to which he was from the first closely associated with William of Orange. But his conduct as a statesman was as weak and vacillating as it had been prompt and audacious

in the field; and, swayed by the contrary motives of sympathy with the popular movement, loyalty to the throne, and devotion to the Roman Catholic church, he accomplished by alternate hesitation and rashness only his own ruin. In 1559 Egmont and the prince of Orange were appointed members of the state council of the Netherlands under the regent Margaret of Parma; but being excluded from consultation on the most important affairs of state, they addressed (July 23, 1561) a joint letter of remonstrance to Philip. Egmont united with Orange and Horn (March 11, 1563) in another letter to the king, urgently remonstrating against the extent of the authority of Cardinal Granvelle, a leading member of the council, who was declared to be odious to many of the people. The unpopularity of Granvelle increased daily, and the most reckless and resolute of his opposers was Egmont, who despised him for his low birth, and hated him for his airs of superiority. At a banquet given to a party of Flemish noblemen it was decided to invent for their meeting a livery that should symbolically express a general contempt for the cardinal. Dice was thrown to decide who should devise the theatrical costume; and the prize, which ultimately proved a deadly one, fell to Egmont. His retainers appeared in a few days in the famous fool's cap livery, which immediately became the reigning fashion, and which, together with the numerous pasquinades and pamphlets, drove Granvelle from the Netherlands. Thus far Egmont had acted under the eye and influence of William of Orange. In 1565 he was sent as special envoy to Spain to enlighten the Spanish court concerning the affairs of the Netherlands; but he became the dupe of royal smiles and favors, and returned to his country only to discover that his mission had been fruitless. For a year his course was uncertain and fitful, after which he departed for his government of Flanders, then in rebellion against the royal edicts. Had Egmont now put himself at the head of the reformers, he might undoubtedly have seized the capital, imprisoned the regent, and made himself master of the country; but on the contrary, he exerted himself with all his energy with extreme severity against the insurgents and Protestants. He continued enthusiastic in his loyalty, offering to throw himself into Walcheren against the rebels who had taken refuge there, risking his life at Valenciennes to reconnoitre the works and suggest the best point of assault, and avowing his intention at a meeting with Orange at Willebroek never in any case whatever to take arms against the king. At the arrival of Alva in the Netherlands in 1568 Orange escaped from the country, but Egmont remained to receive and do honor to the monarch who came armed with his death warrant. Alva arrested him by stratagem together with Count Horn at Brussels, and conveyed them under strong military escort to Ghent, where for months they were kept in rigorous confinement. In vain Egmont claimed to be tried by one

the 3 courts whose jurisdiction alone he recognized. As a knight of the golden fleece it was his privilege to be tried by its statutes; as a noble of Brabant he claimed the protection of the *Joyeuse Entrée*; and as a count of the holy Roman empire, he should be tried by his peers, the electors and princes of the realm. He was brought before the tribunal known in history as the "council of blood," was charged with having been a party to the league and conspiracy of the prince of Orange and his associates, and with having committed sundry malpractices to the prejudice of the government and of the Catholic church, and after little more than a mock trial was adjudged guilty of treason and rebellion. His later zeal in the service of the government had not atoned in the minds of Philip and Alva for his earlier acts of opposition. Meantime the prince of Orange had thrown down the gauntlet, as the avowed champion of his country's wrongs, and it was designed to strike terror to the heart of the people by making the execution of Egmont and Horn an impressive and appalling spectacle. On June 5, 1568, 3,000 Spanish troops were drawn up in battle array around the scaffold in the great square of Brussels, and, while all business was suspended and the bells of the churches were tolling, Egmont was beheaded, after having expressed a bitter regret that he had not rather been permitted to die, sword in hand, fighting for his country and king. Even the soldiers shed tears as they beheld the death of the most gallant and famous of their generals; a cry of horror rose from the multitude; and the French ambassador exclaimed that he had seen the head of that man fall before whom France had twice trembled.—Egmont is the subject of one of Goethe's tragedies. The best account of his career and character is given in Motley's history of the "Rise of the Dutch Republic" (New York, 1856). See also Prescott's "History of Philip II."

EGRET, a name given to those species of white herons which have the feathers of the lower part of the back elongated and their webs disunited, reaching beyond or to the tail, at certain seasons of the year; their forms are also more graceful than those of common herons. They belong, however, to the same genus *ardea* (Linn.), of the order *grallæ*. The great American egret (*A. egretta*, Gmel.) is about 37 inches long to end of tail, 49 to end of claws, with an extent of wings of 55 inches; bill $4\frac{1}{2}$ inches, tail $6\frac{1}{2}$, tarsus 6; anterior toes $2\frac{1}{2}$, 4, and $3\frac{1}{2}$ inches, with the claws $\frac{1}{2}$, $\frac{1}{2}$, and $\frac{2}{3}$ of an inch respectively; the hind toe $1\frac{1}{2}$, and its claw $1\frac{1}{2}$ inches long; weight about $2\frac{1}{2}$ lbs.; the female is somewhat smaller. The bill is straight, tapering to an acute tip; the head compressed and oblong; neck long and slender; body compressed; feet, tarsus, and tibia long, the latter bare in its lower half. The space between bill and eye, and around the latter, is bare; the plumage is soft and blended; head not crested, though its feathers are elongated, as are those on the lower neck in front;

from between the shoulders arises a tuft of long, decurved, and delicate disunited feathers, extending about 10 inches beyond the tail; the wings are moderate, and the tail short, of 12 weak feathers; the bill is bright yellow, feet and claws black, and the plumage white, in some parts slightly tinged with yellow. This elegant bird is found breeding from Florida to New York, and along the shores of the gulf of Mexico to Texas, and probably further; it is rarely seen in Massachusetts, and does not appear more than 50 miles inland, unless along the courses of large rivers; it generally breeds in low marshy places, dismal swamps, and the margins of lakes and ponds; the nests are sometimes made on low bushes, and occasionally on sandy islands near the coast, but generally on high trees. The long, silky filaments of the back are hardly to be seen except in the love season, which varies from early spring to midsummer, according to latitude; both sexes possess them, and many are shot during the breeding season to obtain these feathers for ornamental purposes. It feeds by day, on small fishes, crustacea, and reptiles, which it catches in the shallows and marshes; its flight is well sustained, and its gait and movements are graceful. The nest is made of loose sticks, overhanging the water, and is used for years by the same birds, which annually repair it; the eggs, 2 or 3, are $2\frac{1}{2}$ inches long, when freshly laid smooth and pale blue, becoming afterward rough and whitish. The egret is shy and difficult to obtain, except in the breeding season; many of the young are destroyed by crows and turkey buzzards.—The European egret (*A. alba*, Gmel.) is about 3 feet 5 inches long, of a pure white plumage. According to Selby, the bill is black or dark brown, yellow at the base and about the nostrils, and the legs are almost black. It is common in southern Europe, but comparatively rare in the northern and central parts; the white herons of Asia are believed to be of this species. The little European egret (*A. garzetta*, Linn.) is about 22 inches long from bill to end of tail; the plumage is white; from the hind head spring 2 narrow feathers 4 inches long; the plumes of the back are elongated; the bill and tarsi are black; the tarsus is 4 inches long. This species is confined to the eastern hemisphere, being most abundant in southern Europe, Greece, and northern Africa; it occasionally wanders as far as England. The buff-backed egret (*A. Coromanda*, Bodd.) is about 20 inches long, the bill 2 inches and orange yellow; the plumage is white, except the top of the head and front neck, which are buff, becoming browner as the bird grows older; it is very generally distributed over Asia. The reddish egret (*A. rufa*, Bodd.), of which Peale's egret is the young, is about 31 inches long, and 46 in extent of wings; the pale bill has a black tip; the iris is white; the feathers of the head and neck are loose and pendent, of a light reddish brown tinged with lilac, fading into brownish white at the tips; the back and wings grayish blue; long feathers of the back yellowish-tipped;

pale grayish blue below. It seems never to go far from the Florida keys, except westward along the gulf of Mexico; it is a plump and graceful bird, and an easy and high flier; it is shy, rarely associating with other species; it is probably strictly marine. The nests are made by the middle of April; the eggs are 8, of a pale sea-green color, and are excellent food.

EGYPT (Gr. *Aiyvrrros*; Lat. *Ægyptus*; Heb. *Mizraim*; Coptic, *Chami* or *Kemi*), a country in the N. E. of Africa, bounded N. by the Mediterranean, E. by the Red sea and Arabia, S. by Nubia, and W. by the Great Desert. It lies between lat. $31^{\circ} 87'$ and $24^{\circ} 1' N.$, and long. $27^{\circ} 13'$ and $34^{\circ} 12' E.$ Its length from N. to S. in a direct line is about 520 m.; its breadth from E. to W. varies from 300 to 400 m.; area, including the desert regions, about 200,000 sq. m. The river Nile enters Egypt from Nubia at the island of Philæ near Asswan, the ancient Syene, where it descends the famous cataracts, and flows thence unbroken by falls or rapids, and not augmented by any branch, nor even by a rivulet, till it reaches the Mediterranean. From the cataracts the river, whose general breadth is about half a mile, runs for 600 m. through a valley bounded by hills varying in height from 300 to 1,200 feet. The average breadth of the valley is 7 or 8 m., its greatest breadth 11 m. Anciently the whole of this valley was called Upper Egypt, but afterward the term Middle Egypt was applied to the northern part of it. About 100 m. from the sea, the hills disappear, and the river enters an extensive and perfectly level alluvial plain, where, 12 m. N. of Cairo, it separates into two great streams, which continually diverge until they reach the Mediterranean by mouths about 80 m. apart, the eastern at Damietta, and the western at Rosetta. This great plain is Lower Egypt. The triangular space enclosed by the two arms of the river and the sea is called the Delta, from its resemblance in shape to the Greek letter Δ . But the term Delta is also sometimes applied to the whole plain, or to so much of it as consists of fertile land. The area of the Delta and of the valley of the Nile in Egypt is variously estimated at from 11,000 to 17,000 sq. m. This comprises all the cultivable land, the rest of the country consisting of deserts, with the exception of a few oases and of the region called Fayoom, which lies at no great distance W. of the Nile, between lat. 29° and 30° , and has a fertile area of 340 sq. m. The largest of the oases, the one most remote from the Nile, is Siwah, the ancient Ammonium, the site of the temple and oracle of Jupiter Ammon. It lies 10 days' journey W. of Fayoom, and has an area of only 15 or 20 sq. m. The desert between the Nile and the Red sea is intersected by chains of mountains whose highest summits attain an elevation of 6,000 feet.—The most noted lake of Egypt is the Birket-el-Karoun, in the N. W. part of Fayoom; it is 30 m. long and 6 m. broad. The remains of the famous ancient artificial lake Moeris have been recently identified in the E. part of Fayoom. To the north

of the Birket-el-Karoun, at the distance of 50 m., are the natron lakes, from which the water evaporates in the dry season, leaving the ground covered with a crust of natron or carbonate of soda. Along the sea-coast of the Delta there is a series of large lagoons stretching for nearly 200 m., of which the principal are Lake Maryoot, the ancient Mareotis, 40 m. long, Lake Boorlos, 30 m. long, and Lake Menzaleh, 50 m. long, with an average breadth of 15 m. From a very ancient period Egypt has abounded in canals, chiefly constructed to facilitate the distribution of the water of the Nile for purposes of irrigation. The Mahmoudy canal, 50 m. long and 100 feet broad, was made in 1820 to accommodate the commerce between Alexandria and the Nile. In the beginning of 1859 Egypt had about 500 m. of railroad completed. The principal lines are from Alexandria to Cairo, 131 m.; from Cairo to Suez, 91 m.; and from Cairo to Beni-Souef, up the Nile, 76 m. The railroad bridge across the Nile at Kafr-el-Zyat is one of the greatest works of the kind in the world, and is expected to be completed in June, 1860. Another great work commenced several years ago, but not yet finished, is the *barrage* or dam across the Nile at the beginning of the Delta, designed to heighten and regulate the annual inundation. The construction of a canal across the isthmus of Suez to unite the Red sea with the Mediterranean was begun April 25, 1859.—The most striking geological feature of Egypt is the vast bed of alluvium deposited by the Nile, which covers all Lower Egypt to a depth that probably averages 30 or 40 feet. The predominant rocks of the country are limestone, sandstone, and granite. The great pyramids are built of limestone, and stand on a limestone plateau. This rock extends up the valley of the Nile as far as Esne, and from thence to Asswan or Syene sandstone prevails, from the quarries of which most of the temples of Egypt have been built. At Syene, at the southern extremity of the country, granite predominates, and the quarries there have furnished chiefly the materials for the obelisks and colossal statues of Egypt. The soil of Egypt is of unsurpassed fertility, and its richness is annually renewed by the inundation of the Nile, which deposits upon the land a coating of mud which renders needless any other manure. In many parts ploughing is dispensed with, the seed being thrown upon the mud, and sheep, goats, or pigs turned loose in the fields to trample in the grains; though in other parts agriculture is carried on with considerable labor and care, especially where artificial irrigation must be resorted to. The rise of the Nile begins in Egypt in the latter part of June. The inundation reaches its greatest height between Sept. 20 and 30, when it is usually 24 feet above the low water level. It remains at that height about 15 days, and then gradually falls, till it is at the lowest about the middle of May. It rises sometimes 30 feet, when it does great damage to the country. If it fall short of 18

feet, a famine is the consequence. The following plants are sown immediately after the inundation begins to subside, and are harvested 3 or 4 months later: wheat, barley, beans, peas, lentils, vetches, lupins, clover, flax, lettuce, hemp, coriander, poppies, tobacco, watermelons, and cucumbers. The following plants are raised in summer chiefly by artificial irrigation: durra, maize, onions, henna, sugar cane, cotton, coffee, indigo, and madder. Grapes are plentiful, and other fruits abound, of which the most common are dates, figs, pomegranates, apricots, peaches, oranges, lemons, citrons, bananas, mulberries, and olives. There are no forests in Egypt, and few trees of any kind except the palm, of which there are usually groves around the villages. From the absence of forests there are few wild beasts, the principal species being wolf, fox, jackal, hyena, the wild ass, and several kinds of antelope. The chief domestic animals are camels, horses, asses, horned cattle, and sheep. The hippopotamus is no longer found in Egypt, though it is met with in the Nile above the cataracts, and the crocodile has abandoned the lower part of the river, and is becoming rare even in Upper Egypt. Among the birds are 3 species of vultures (one of which is very large, individuals sometimes measuring 15 feet across the wings), eagles, falcons, hawks, buzzards, kites, crows, linnets, larks, sparrows, and the beautiful hoopoe, which is regarded with superstitious reverence. Pigeons and various kinds of poultry are very abundant. The ostrich is found in the deserts. Among the reptiles are the cerastes and naja haje, both deadly poisonous. Fishes abound in the Nile and in the lakes, and furnish a common and favorite article of food. Locusts occasionally invade the country and commit great ravages. The climate of Egypt is singularly dry and equable, and is healthy, though excessively hot in summer, the mercury rising sometimes to 112°. The winter is mild and serene, snow being almost unknown. In Upper Egypt rain is so rare that a slight shower is looked upon as a prodigy. In the Delta a small quantity of rain occasionally falls in winter. The most common diseases are dysentery, liver complaints, and ophthalmia, the latter being often met with. The plague was formerly frequent and virulent, but owing to the sanitary precautions of the government it has not made its appearance since 1843. One of the most disagreeable features of the climate is the khamisin, a hot wind from the desert which prevails for 50 days in the spring, beginning generally about May 2, and has a peculiarly oppressive and unhealthy effect.—Egypt is now divided into 7 provinces, which are subdivided into departments, and these again into lesser districts. Anciently, under its native rulers and their Persian, Greek, and Roman successors, the country was divided into districts called nomes, varying in number at different eras from 36 to 56 or 58. The capital of Egypt is Cairo, and the other principal towns are Alexandria, Rosetta, and Damietta. There

is much uncertainty about the amount of population. A government census in 1847 officially stated the number of inhabitants at 4,542,620. A census taken during the present year (1859) gives a total of 5,125,000. By foreign observers of judgment and accuracy, these censuses are discredited and their results held to be grossly falsified and exaggerated. Sir Gardner Wilkinson computes the population at only 1,800,000. By others it is supposed to be about 2,500,000, of whom 2,000,000 are Mohammedans and call themselves Arabs, though they are probably in great part descended from the ancient Egyptians. They are a fine race, handsome, well made, and courteous in their manners. In northern Egypt they are of a yellowish complexion, growing darker toward the south, until the hue becomes a deep bronze. Mr. Lane, the best authority upon the subject, speaks highly of their mental capacity, and gives them credit for uncommon quickness of apprehension and readiness of wit. They are highly religious, and are generally honest, cheerful, humane, and hospitable. The Arabs of pure blood belonging to Egypt are chiefly Bedouins who dwell in tents in the desert, and number about 250,000. There are 150,000 native Christians termed Copts, who are the recognized descendants of the ancient inhabitants. They are generally employed as clerks and accountants in government and mercantile offices. Beside these there are Turks, the ruling class, of whom there are about 20,000, and Armenians, Greeks, Berbers, Jews, and Franks. Agriculture is the chief pursuit of the people, and furnishes all the staples of export. Wheat, beans, barley, Indian corn, linseed, sesame, cotton, wool, flax, and henna are annually exported to the amount of about \$16,000,000. Wheat is the principal article of export, and about 5,000,000 bushels, or $\frac{3}{4}$ of the entire crop, are sent to Europe annually. Of cotton the average annual export for several years past has been nearly 200,000 bales. The annual amount of imports is about \$14,000,000; the principal articles are timber, copper, coal, woollen, cotton and silk goods, drugs, tinware, paper, oil, jewelry, sugar, glass, tobacco, spices, and coffee. The foreign commerce is chiefly with Great Britain, France, and Austria, and is carried on through the port of Alexandria. An extensive trade by means of caravans is maintained with the interior of Africa. The manufacture of firearms, and of cotton, silk, and woollen goods, is carried on extensively in establishments founded and directed by the government.—Egypt is a dependency of the Turkish empire, and is governed despotically by a pasha of the family of Mehemet Ali, with whom the Turkish sultan made a treaty in 1841, by which it was agreed that the government of the province should be confirmed to him, and in succession to the then living members of his family. A tribute of $\frac{1}{3}$ of the revenue is annually sent to the sultan, to whom also all appointments to posts in the army above the rank of major have to be referred for confirmation.

The number of the army is limited to 18,000 men, though this regulation has not been strictly observed. There are ministers of foreign and internal affairs, of war, navy, finance, and public instruction. The government maintains about 50 schools of various grades, a school of languages, another of medicine, several military schools, and a printing press. There are 4 principal courts of justice, whose seat is at Cairo: that of the chief of police, which summarily decides petty cases; that of the *cadi*, or chief judge; that of the mufti, or chief doctor of the law; and that of the pasha's divan. There is also a *cadi* in each town and village, who dispenses justice, and each province and subdivision of the country has a governor clothed with a certain degree of judicial power. The dominion of the Egyptian pasha has been extended by recent conquests far up the Nile over Nubia, Dongola, Sennaar, Kordofan, and other barbarous regions, to the confines of Abyssinia. —The history of Egypt divides itself into 6 great periods: 1, the Pharaohs, or native kings; 2, the Persians; 3, the Ptolemies; 4, the Romans; 5, the Arabs; 6, the Turks. The main sources of its history under the Pharaohs are the Scriptures, the Greek writers Herodotus, Diodorus, and Eratosthenes, some fragments of the writings of Manetho, an Egyptian priest in the 3d century B. C., and the hieroglyphic inscriptions on the monuments, that is, on the temples, tombs, and other buildings of ancient date. From works written on rolls of papyrus, found in the tombs, information has also been derived by recent Egyptologists. There is still, however, much uncertainty and controversy as to the true interpretation of the hieroglyphics, and scarcely any two authors agree either with regard to names or dates; though the discrepancies in regard to names are immaterial, while those in the chronology are wide and apparently irreconcilable. The chief living authorities upon the interpretation of the hieroglyphics are, in English, Sir Gardner Wilkinson, and in German, Chevalier Bunsen and Dr. Lepsius. From the Scriptures we learn that the Hebrew patriarch Abraham went into Egypt with his family because of a famine that prevailed in Canaan. He found the country ruled by a Pharaoh, the Egyptian term for king. The date of Abraham's visit, according to the chronology of the Hebrew text of the Bible, was 1920 B. C.; according to the Septuagint, 2551; while Bunsen fixes it at 2876. Nearly two centuries later Joseph, a descendant of Abraham, was sold into Egypt as a slave to the captain of the guards of another Pharaoh, whose prime minister or grand vizier the young Hebrew eventually became. Joseph's father, Jacob, and his family, to the number of 70, accompanied, as Bunsen conjectures, by 1,000 or 2,000 dependents, followed their fortunate kinsman into Egypt, where they settled in a district called the land of Goshen. There they remained until their numbers had multiplied into 2 or 3 millions, when under the lead of Moses they revolted and quitted Egypt

to conquer and possess the neighboring land of Canaan. The date of their exodus, according to the commonly received Scripture chronology, was 1491 B. C., after a sojourn in Egypt of 215, or, at most, of 480 years. Bunsen assigns the date to 1320 B. C., and maintains the duration of the sojourn in Egypt to have been 1,484 years. From the exodus, for several centuries, the relations between the Hebrews and the Egyptians appear to have been friendly, until in the 5th year of the reign of Rehoboam, about 980 B. C., Shishak, king of Egypt, conquered and plundered Jerusalem, an event the occurrence of which is attested and confirmed by the monuments. The first of the Greek authorities upon Egypt, Herodotus, visited the country about the middle of the 5th century B. C. His knowledge of its history was derived from conversation with the priests of various cities, with whom he talked by means of interpreters. They told him, he says, that Menes was the first king of Egypt, and was succeeded by 330 monarchs, of whom one, Nitocris, was a queen. None of them were distinguished, and none of them left any monuments worthy of note, except Moeris, the last of the 330, who constructed the artificial lake which bears his name. He was succeeded by Sesostris, who conquered Ethiopia and the greater part of Europe and Asia. His successors were Pheron, Proteus (who was contemporary with the Trojan war), Rhampsinitus, Cheops, Cephren, and Mycerinus. The last 3 kings built the 3 great pyramids. Mycerinus was succeeded by Asychis, and Asychis by Anysis, in whose reign Egypt was conquered by the Ethiopians, who held it for 50 years under King Sabaco. At the expiration of the half century they voluntarily abandoned the country and retired to Ethiopia. The next king of Egypt was Sethos, between whom and the first king Menes, the priests told Herodotus, there had been 341 generations, a period of 11,340 years. Sethos was succeeded by 12 kings, who reigned jointly, and together built the Labyrinth, which Herodotus thought surpassed all the works of the Greeks, and was even more wonderful than the pyramids themselves. After the lapse of some years, Psammetichus, one of the 12 kings, dethroned the others and made himself sole sovereign of Egypt. He was succeeded by Necho, Psammis, and Apries, the last of whom Herodotus calls the most prosperous king that ever ruled over Egypt. But in the 25th year of his reign a rebellion broke out which was headed by Amasis. Apries was defeated and put to death, and Amasis became king. Amasis was succeeded by his son Psammenitus, at the very beginning of whose reign, 525 B. C., Egypt was invaded and conquered by the Persians under Cambyses. Diodorus, the next of our Greek authorities, was in Egypt about 58 B. C. Like Herodotus, he begins the line of Egyptian kings with Menes, who, he says, was succeeded by 52 monarchs, reigning 1,400 years. These were succeeded by Busiris I., and 7 or 8 generations

later by Busiris II., who built Thebes. Later still reigned Osymandyas, and after 8 more generations Uchoreus, who built Memphis, and who after 15 more generations was succeeded by Myris or Mæris. Diodorus also relates the exploits of the great conqueror Sesostria, whom he calls Sesoosis. He computes the whole number of native sovereigns of Egypt at 470 kings and 5 queens, and the duration of the native monarchy at 4,700 years. Eratosthenes, who died about 196 B. C., was a native of Cyrene, and was made librarian of the Alexandrian library by Ptolemy III. He wrote a work on universal chronology, fragments of which have been preserved by Syncellus and others. His computation of Egyptian chronology, so far as it goes, has been adopted by Bunsen. Manetho was high priest of Sebennytus about 280 B. C. He wrote a history of Egypt for the information of the Greeks, of which only some extracts have reached us in the works of later writers, who do not agree in their transcription of the most important part of these remains, which is a list of the dynasties and sovereigns of Egypt from the earliest period to the end of the Persian rule. But notwithstanding the occasional discrepancies produced by careless or fraudulent copyists, these "dynasties" of Manetho are of the highest value to Egyptian history, and their general authenticity has been fully established by comparison with the monuments. They comprise 31 dynasties, which reigned successively in Egypt, numbering upward of 300 kings, the sum of the years of whose reigns from Menes to Nectanebo II., 351 B. C., was 3,555 years. "This succession of time," says Bunsen, "the vastest hitherto established anywhere in the old world, is now also the best authenticated. It is based upon lists of kings and their regnal years; and these lists are corroborated and elucidated by contemporary monuments up to the 4th dynasty, with slight breaks; an authentication which is as unexampled as its extent." The era of Menes, according to Bunsen, was 3643 B. C.; according to Lepsius, 3898. Wilkinson remarks of Menes that the frequent occurrence of a similar name in early history, as Manea, the first king of Lydia, the Phrygian Manis, the Minos of Crete, the Indian Menu, the Thibetian Mani, the Siamese Manu, the German Mannus, and others, may seem to assign him a place among mythical beings, but that the Egyptians themselves believed him to be a real personage, and accepted the recorded events of his reign as undoubted facts. He, however, declines in his latest publication to assign to Menes any date, for the alleged reason that no certain era has been established in early Egyptian chronology. In his previous works he had adopted the date of 2950 B. C. as the most probable. It is a point still in dispute among Egyptologists whether the first 17 dynasties which succeeded Menes were consecutive. It is maintained by those who are disposed to assign to the beginning of Egyptian history the remotest date, that the

dynasties, with inconsiderable exceptions, were consecutive, and that the kings enumerated reigned over the whole of Egypt. By most writers on the subject it is held that many of the dynasties were contemporaneous, and that 2 or more kings reigned at the same time over different parts of Egypt. It is admitted by all that the 18th dynasty and those which succeeded it reigned over the whole of the country. Bunsen divides the dynasties and the history of Egypt under them into 3 great masses: 1, the old empire, from Menes to Amyntimæus, including the first 12 dynasties of Manetho and part of the 13th, and embracing a period of 1,076 years; 2, the middle period, or the period of the shepherd kings, 922 or 929 years; 3, the new empire, from the 18th to the 30th dynasty, about 1,300 years. Lepsius dissents from this arrangement in some respects, and reckons the length of the first period at 1,286 years instead of 1,076. He also maintains that there always were native Egyptian dynasties contemporary with the shepherds, and divides the dynasties merely into the old empire and the new. Wilkinson, however, regards this division into the old and new empires as purely arbitrary and unnecessary. The capitals of the 1st and 2d dynasties seem to have been in Upper Egypt, but the seat of the 3d dynasty was at Memphis in Lower Egypt. The kings of the 4th dynasty, who reigned also at Memphis as early at least as 2450 B. C., were builders of pyramids, which were intended for their tombs. The monuments show that at this period the Egyptians had already made great advances in the arts and habits of civilized life. The masonry of their buildings was equal to that of any other period, ancient or modern, and their sculpture of the human form was better than it was in a later and more conventional age. The art of making glass was known, and the furniture, costumes, implements of trades and agriculture, and the manners and customs of the people, are apparently as indicative of a refined civilization as at any subsequent period. Two brothers of this dynasty, who seem to have reigned together, Suphis or Shufu I. and II., the Cheops of Herodotus, were the builders of the great pyramid, which was their tomb and in which their names have recently been found inscribed. The second pyramid was built by Shafré or Sepses, the Cephren of Herodotus, and the 3d pyramid by Menkaré or Mencheres, whom Herodotus calls Mycirinus. A portion of his coffin, taken from his pyramid by Gen. Vyse a few years ago, is in the British museum. The 6th dynasty, according to some authorities, immediately succeeded the 4th at Memphis, while the 5th at the same time reigned in Upper Egypt. At the end of the 6th dynasty, according to Wilkinson, 2240 B. C., Lower Egypt was conquered by invaders from Asia, who established themselves at Memphis and made the sovereigns of Upper Egypt their tributaries. These invaders were called by the Egyptians shepherds, and their kings, of whom several dynasties reigned at Memphis, are called the

shepherd kings. Nothing whatever is known of their origin, but it has been conjectured that they were a pastoral race, either Arabs, Scythians, or Tartars, who emigrated from their native seats and conquered Egypt, as in later ages the Goths, Huns, Mongols, Magyars, and Turks subdued and occupied remote countries. The date of their inroad into Egypt is placed by Bunsen at about 2567 B. C. Lepsius, on the contrary, computes it to have been more than 500 years later, at about 2000 B. C. The 12th dynasty began about 2000 B. C., according to Wilkinson. Its capital was Thebes, and several of its monarchs, among others 3 of the name of Osirtasen or Sesortasen, were highly distinguished. Osirtasen I. was a conqueror, who seems to have carried his arms southward into Ethiopia, and to have regained nearly the whole of Egypt from the shepherd kings, who, however, still held Memphis, and part of Lower Egypt. He is supposed to have been the original Sesostri, so famous among the Greeks, though in after ages a still greater monarch and conqueror, Rhamses II., became confounded with Osirtasen I., and the achievements of both were attributed to a single Sesostri by the Greek historians and poets. Osirtasen III. also made conquests in Ethiopia, and his memory was so highly respected that divine honors were paid to him long after his death by some of the kings of the 18th dynasty. By some Egyptologists he also is supposed to have been the prototype of Sesostri. Osirtasen I. built the temple of Heliopolis, where to this day stands one of the finest obelisks in Egypt, erected by him and inscribed with his name. He also excavated the principal of the grottos of Beni Hassan, in which the arts, manners, and customs of his age are vividly depicted with a minuteness and variety of detail that have given us a better acquaintance with the domestic life of Egypt 4,000 years ago than we have with the same feature of European existence 3 or 4 centuries since. Under the next dynasty, the 13th, about 1860 B. C., the shepherd kings seem to have recovered their supremacy in Egypt, and to have driven the Theban monarchs to take refuge in Ethiopia. Under several dynasties the conquerors held the country till Amés or Amosis, the first king of the 18th dynasty, who brought aid from Ethiopia, headed a successful revolt of the Egyptians, and drove the shepherds out after a long struggle, which ended with the capitulation of their last stronghold, the frontier city of Avaris, from which they withdrew into Syria. According to Wilkinson, this took place about 1500 B. C., after the shepherds had possessed Egypt 511, or at the most 625 years. According to Bunsen, the shepherds were expelled in 1548 B. C., after having occupied Egypt under 43 kings for 922 or 929 years. He attributes their final expulsion to Tuthmosis III., a grandson of Amosis, though he maintains that Amosis recovered the greater part of Egypt from their grasp and reestablished the throne of the Pharaohs in Memphis. Tuthmosis III. is called Thothmes III. by Wilkinson, who says

that his reign was one of the most distinguished in the history of the Pharaohs. He extended his arms far into Asia, from which he received a large tribute; and the elephants and horses, the rare woods, bitumen, rich gold and silver vases, ebony, ivory, giraffes, apes, gold dust, ingots, and rings, pictured on the monuments of his reign, show not only the value of the tributes, but the distance from which they were brought. "The great additions he made to Karnak and other temples in Thebes," says Wilkinson, "and the remains of monuments bearing his name at Memphis, Heliopolis, Coptos, Ombos, and other cities in different parts of Egypt, show how much was done by Thothmes to beautify them and to commemorate the glories of his reign; and the style as well as the high finish of his sculptures were not much surpassed at any subsequent period. He has left more monuments than any Pharaoh except the second Remeses." Rosellini, the distinguished Italian Egyptologist, remarks that there is hardly an ancient city in Egypt and Nubia, as far as the second cataract beyond Semneh, where remains of the edifices of Thothmes III. are not to be found. Thothmes IV., his grandson, caused the great sphinx at the pyramids to be cut out of the rock. Amunoph or Amenophis III., another king of this 18th dynasty, was known to the Greeks and Romans as Memnon, and his colossal statue at Thebes was the famous vocal statue which was supposed to salute the sunrise with a clear-toned sound. His conquests and his power were very extensive, his empire comprising Ethiopia, a large part of Arabia, Syria, and Mesopotamia, and he is supposed to have introduced innovations or heresies in the national religion of Egypt, and to have prepared the way for the great religious revolution which took place under the "stranger kings," as the Egyptians termed them, by 7 of whom he was followed in immediate succession. Of these monarchs very little is known. They seem to have been usurpers or invaders of foreign race, to have ruled tyrannically, and to have supplanted the national gods of Egypt by the worship of the sun. Their capital was at or near the modern village Tel-el-Amarna in Middle Egypt. Their memory was so detested by the Egyptians that after their expulsion from the throne their monuments and inscriptions were everywhere destroyed or defaced. Their reigns were short, not more than 30 years in all, according to Wilkinson's calculation, and terminating about 1324 B. C. It was in the reign of Pthahmen, one of these kings, that Wilkinson supposes the exodus to have taken place, when the children of Israel went forth out of the land of Egypt under the leadership of Moses and Aaron. Bunsen coincides with this view of the date of the exodus, though he gives the name of the Pharaoh who ruled Egypt at the time as Menephthath. The date he fixes at 1320 B. C. Abraham he supposes to have visited Egypt about 2876 B. C. in the reign of a Pharaoh of the 8th dynasty, and Jacob to have settled in the land of Goshen with his family in the 9th year of Osirtasen I., 2754

B. C. The length of the sojourn of the Israelites in Egypt he thus computes at 1,434 years. The 19th dynasty, which began about 1324 B. C. with Rhamses I., reigned during the most illustrious period of Egyptian history, when the extent and power of the empire were at their highest pitch, and when the most splendid monuments were erected at Thebes, and in fact throughout the country. The great monarchs of this dynasty were Sethos or Sethi I. and Rhamses II., the son and grandson of Rhamses I., the founder of the line. Sethos made extensive conquests in Africa and Asia, and waged successful wars with the Assyrians and Medes. He built many superb edifices at Thebes, among others the great hall of Karnak, on the walls of which his victories are sculptured, and his tomb excels all others in Egypt in the beauty and richness of its sculptures and paintings. According to Bunsen, Sethos, or Sethosis, as he calls him, was the true original of Sesostris, the celebrated hero of Egypt. Rhamses II., his son, reigned 66 years, and, inheriting a mighty empire and a great and veteran army, achieved brilliant victories over the surrounding nations, and erected numerous monuments by the labor of the captives whom he brought home from his campaigns. Wilkinson, on the contrary, though admitting the glory and power of Sethos, considers his son the greater monarch and the true Sesostris. He fixes the beginning of his reign at 1311 B. C., and says that this period may be regarded as the Augustan age of Egypt, in which the arts attained to the highest degree of excellence of which they were then capable. A century later, after several obscure and feeble reigns, Rhamses III. of the 20th dynasty revived the martial renown of his name, and penetrated to remote countries in Asia, to which the arms of Egypt had never before reached. He seems even to have encountered and defeated some Tartar nations. With him, says Wilkinson, closes the glorious era of Egyptian history. Rhamses VIII., however, whose reign began 1171 B. C., maintained the foreign possessions of Egypt, and has left some striking monuments on which his own portrait, conspicuous for the high bridge of his nose, is yet to be seen. The first king of the 22d dynasty was Sheshonk I., 990 B. C. He was the Shishak of the Scriptures (1 Kings, xi. 40), who was contemporary with Solomon; and in the 5th year of Rehoboam, king of Israel, he captured Jerusalem and pillaged the temple. The sculptured record of this campaign is still to be seen on the wall of the great temple of Karnak, with the name of Juda Melchi, or kingdom of Judah, yet legible, together with the portrait of a captive with strongly marked Jewish features. From the time of Sheshonk Egypt declined in power, not improbably because of the rapid growth at this period of the Assyrian empire. At the beginning of the reign of Psammenitus, the last king of the 26th dynasty, 525 B. C., Egypt was conquered by Cambyses, and became a Persian province governed by a satrap. The people frequently revolted

and were as often subdued, but at length, about 411 B. C., they succeeded in driving out the Persians, and with the aid of Greek auxiliaries maintained their independence under a series of native monarchs, the last of whom was Nectanebo II., who was conquered and dethroned by Ochus or Artaxerxes III., in 351 B. C. Egypt continued a Persian province, however, only till 332 B. C., when it was conquered by Alexander the Great.—Of the manners and customs, mode of life, and social condition of the ancient Egyptians, we can form a very satisfactory opinion from the representations on the monuments. It is evident from their testimony that at a very early age the Egyptians were a highly civilized people, wealthy, industrious, with a fully organized society, and great proficiency in arts, manufactures, and agriculture. Of their literature we know little, the few remains that have reached us being too scanty to enable us to judge with confidence of the general character of their intellectual productions. A large number of papyri have been found, containing writings, some of a historical and others of a religious nature, but they have not yet been so perfectly deciphered as to be fully understood. The religious documents all belong to one work, which was called by Champollion the "Funeral Ritual," but which Lepsius terms the "Book of the Dead." This work, which seems to be alike poor in matter and style, consists chiefly of prayers and of instruction about the future life. The historical papyri relate to the exploits of some of the kings, which are told in a bombastic manner. A very curious romance or fairy tale of the age of the 19th dynasty has been discovered and translated into French. Some collections of letters written by scribes, a biographical memoir of a scribe, and a number of miscellaneous fragments have also been found. The progress of the Egyptians in sculpture and painting was hampered by religious restraints which prevented their development beyond a point which was early reached. In architecture, however, they occupy perhaps the most distinguished place among the nations. No people has equalled them in the grandeur, the massiveness, or the durability of their structures. A competent authority, Fergusson, the author of the "Illustrated Handbook of Architecture," says: "Taken altogether, perhaps it may be safely asserted that the Egyptians were the most essentially a building people of all those we are acquainted with, and the most generally successful in all they attempted in this way. The Greeks, it is true, surpassed them in refinement and beauty of detail, and in the class of sculpture with which they ornamented their buildings, and the Gothic architects far excelled them in constructive cleverness; but beside these, no other style can be put in competition with them. At the same time neither Grecian nor Gothic architects understood more perfectly all the gradations of art, and the exact character that should be given to every form and every detail. They understood, also, better

than any other nation, how to use sculpture in combination with architecture, and to make their colossi and avenues of sphinxes group themselves into parts of one great design, and at the same time to use historical paintings, fading by insensible degrees into hieroglyphics on the one hand, and into sculpture on the other, linking the whole together with the highest class of phonetic utterance, and with the most brilliant coloring, thus harmonizing all these arts into one great whole, unsurpassed by any thing the world has seen during the 30 centuries of struggle and aspiration that have elapsed since the brilliant days of the great kingdom of the Pharaohs."—Of the religious system of the Egyptians we possess very scanty information. The people worshipped many gods, and each city or district had its tutelar deity, who in that place was particularly adored, while in the rest of the country he was little regarded. The principal gods were Osiris and Isis, who were worshipped throughout Egypt; Amun, or Ammon, who like Jupiter was held to be the "king of gods," the especial tutelar deity of Thebes; Noum, the god of the cataracts and oases, who in later times under the Romans was called also Ammon, and considered the same as Jupiter; Sálé, his wife, who corresponded to Juno; Phthah, the Memphian deity, who symbolized the creative power; the goddess Neith, worshipped at Sais, who may be compared to Minerva; Kem, who represented universal nature, and particularly the generative principle, and whose chief temples were at Coptos and at Chemmis; the goddess Pasht, whose worship prevailed at Bubastis, and who corresponded to the Artemis or Diana of Greek and Roman mythology; Maut, the maternal principle; Re or Phrah, the sun; Seb, the earth, who was called "father of the gods;" Nepte, the sky, wife of Seb, the "mother of the gods;" Moui, the sunlight; Atmou, the darkness; Thoth, the intellect. Other noted deities were Khons, Anouke, Tafne, Savak, Eileithyia, Mandou, Seth, Nepthys, Horus, and Athor. A great variety of abstract principles and even of animals and vegetables were however worshipped by the multitude, though the doctrine of one God was privately taught by the priests to a select few. To each deity an animal seems to have been held sacred, which was probably regarded as his symbolical representative. Bulls were consecrated to Osiris and cows to Athor; the sacred bull of Memphis, called Apis, being particularly venerated throughout Egypt. A hawk was the symbol of Re, the ibis of Thoth, the crocodile of Savak, and the cat of Phthah. Of the doctrines of the Egyptian religion little is accurately known. The existence of the spirit after death was believed, and a future state of rewards and punishments inculcated, in which the good dwelt with the gods, while the wicked were consigned to fiery torments amid perpetual darkness. It was believed that after the lapse of ages the spirit would return to the body, which was therefore carefully embalmed and preserved in

elaborately constructed tombs.—The government of Egypt was a monarchy, limited by strict laws and by the influence of powerful hereditary privileged classes of priests and soldiers. The priests were the ruling class. They were restricted to a single wife, and if polygamy was permitted to the rest of the people, it must have been very seldom practised. The marriage of brothers and sisters was permitted. The laws were wise and equitable, and appear to have been rigidly enforced. Murder was punished with death, adultery by bastinadoing the man and by cutting off the nose of the woman, forgery by cutting off the culprit's hands. Imprisonment for debt was not permitted, but a man could pledge to his creditors the mummies of his ancestors, and if he failed in his lifetime to redeem them, he was himself deprived of burial. Women were treated with respect, and the laws and customs seem to have been so favorable to them that their condition in Egypt was much higher than in any other nation of antiquity. The military force of Egypt was a species of hereditary militia, which formed one of the leading classes or castes, and in time of peace cultivated the land, of which it held a large portion. The king's guards, some few thousands in number, were the only standing army. The number of soldiers in the military caste is stated by Herodotus at 410,000, which probably included all the men of that class able to bear arms. It is not probable that the whole of them ever were or could be brought into the field at once. Their arms were spears and swords, and they were protected by large shields. They were distinguished for their skill as archers, and also used the sling. They do not seem to have been well supplied with cavalry, though they made much use of war chariots.—The researches of modern investigators have established the fact that the ancient Egyptians were of the Caucasian type of mankind, and not of the negro. Their language bore unmistakable affinities to the Semitic languages of western Asia, such as the Hebrew and the Arabic. Herodotus, it is true, speaks of them as black and woolly haired, but the mummies, of which immense numbers remain, prove that his words are not to be taken literally. The shape of their skulls is Asiatic, not African; and the paintings on the monuments show that they were neither black like the negro nor copper-colored like some of the Ethiopian tribes. The true negroes are distinctly represented on the monuments, and in a style of caricature which the Egyptians would not have applied to themselves. There is, however, reason to believe that the Egyptians had mixed largely with the negroes, and from the positive statements of Greek and Roman eye-witnesses there can be no doubt that they were of very dark complexion. We have no certain knowledge of the amount of population under the Pharaohs. By some of the Greek and Roman writers the number of inhabitants at the most flourishing periods is stated to have been

7,000,000, a prodigious amount for so small a country, the average number to the square mile, exclusive of the desert, being twice as large as in the most densely peopled lands of modern times. Still, so great was the fertility of Egypt that the statement is not improbable. The cultivable land is somewhat greater in extent now than it was in antiquity, owing to the wider spread of the inundation of the Nile; and it is computed that if properly tilled it would yield more than is requisite for the food of 8,000,000 people, though without allowing any considerable surplus for exportation. Under the ancient Pharaohs little or no corn was exported, and the land seems to have been carefully cultivated. Another statement of the Greeks and Romans, that at the height of her prosperity there were in Egypt 20,000 cities, is altogether preposterous. The country contained several large and populous cities, the most considerable of which were Thebes, Latopolis, Apollinopolis, Syene, in Upper Egypt; Memphis, Heracleopolis, Arsinoë, in Middle Egypt; Heliopolis, Bubastis, Leontopolis, Sais, Busiris, Naucratis, Mendes, Tanis, Pelusium, in Lower Egypt. At the lowest computation these great cities can scarcely have contained in the aggregate less than 2,000,000 people, which, deducted from the 7,000,000 of total population, would have left but an average of 250 inhabitants to each of the 20,000 cities.—The conquest of Egypt by Alexander the Great was much facilitated by the hatred of the natives to their Persian masters. They welcomed the Greeks as deliverers, and with reason, for with the rule of Alexander came trade, learning, science, the arts, and just and stable government. He conciliated the priests by sacrificing to the sacred bull Apis, whom the idol-hating Persians had treated with indignity; and in order to restore to the people their ancient laws and usages, he established two judgeships, with jurisdiction over the whole country, and appointed two eminent Egyptians to these offices, directing also all the Greek officers to regard the customs of Egypt in administering the government. But the greatest and most permanent benefit which the Macedonian conqueror bestowed upon Egypt was the foundation of Alexandria, whose capacities to be made a port of the first class and an emporium for the commerce of the eastern Mediterranean he perceived at a glance while passing through the place on his way to visit the oracle of Ammon. The city which he ordered to be built there rose rapidly to importance, and in a few years became one of the great capitals of the world and the chief centre of Greek civilization. Alexander effected not merely a political, but a social and intellectual revolution in Egypt, which for a thousand years after the conquest remained essentially a Greek country—the Greeks being the dominant if not the most numerous race. After the death of Alexander, 323 B. C., and the division of his empire among the Macedonian captains, Egypt became subject to Ptolemy, surnamed Soter, an able and

enlightened ruler, who after a splendid reign of 38 years abdicated in favor of his son Ptolemy Philadelphus, and died two years afterward. The early part of the reign of Ptolemy Philadelphus was disturbed by civil war with his rebellious brothers, two of whom he put to death. The domestic state of Egypt was greatly improved under his administration, and Upper Egypt, which had been in a turbulent condition for half a century, was reduced to order and made safe for merchants and other travellers. The port of Berenice on the Red sea was constructed, and the city of Arsinoë was built where Suez now stands. Ptolemy also built other cities on the Red sea to facilitate the trade with India, which was at that time extensive and profitable. The museum of Alexandria and its famous library, both founded by Ptolemy Soter, were now at the height of their prosperity. Demetrius Phalereus was librarian, Euclid was head of the mathematical school, and the poets Theocritus, Callimachus, and Philætus were reckoned among the ornaments of the court. The Jews at this time were very numerous in Egypt, and with the king's sanction the Septuagint version of the Old Testament was made from the Hebrew into the Greek by 70 or 72 Jewish scholars. The dominions of Ptolemy beside Egypt comprised a considerable part of Ethiopia, together with Palestine, Coele-Syria, Pamphylia, Cilicia, Lycia, Caria, Cyprus, and the Cyclades. His army is said to have numbered 200,000 foot and 20,000 horse, 2,000 chariots, 400 elephants, and a navy of 1,500 ships of war and 1,000 transports. Commerce and the arts, science and literature, directed by Greek genius and Greek energy, were carried to a height of splendor that rivalled the brightest days of the elder Pharaohs. Alexandria, the capital, was a superb city, adorned with magnificent edifices, and preëminent throughout the civilized world as a seat of learning, science, and trade. Ptolemy Philadelphus reigned like his father 38 years, and was succeeded by his son Ptolemy Euergetes, who had a brilliant and prosperous reign of 25 years. He rebuilt many of the great temples of Egypt and founded others, and his court was thronged by artists and authors. Under his profligate and tyrannical son, Ptolemy Philopator, the kingdom began to decline; and in the reign of the next king, Ptolemy Epiphanes, a minor, the king's guardians were forced to invoke the protection of the Romans against the ambitious designs of the sovereigns of Syria and Macedonia, who had formed a combination against Egypt. The result of their interference was that after a century and a half of turbulence and misrule, under 8 sovereigns bearing the name of Ptolemy, the last of whom, Ptolemy XII., reigned jointly with his sister and wife, the famous Cleopatra, Egypt was reduced to the condition of a Roman province by Augustus Cæsar, 80 B. C. It remained subject to the emperors of Rome for more than 3 centuries, with the short and doubtful exception of a period when it may have been held by Zenobia, the queen of Palmyra. It was

looked upon as the most valuable of the provinces of the empire, as the granary of Rome, upon whose harvests the idle and turbulent millions of the imperial metropolis depended for their daily bread. Its history during this long period is a record only of fruitless rebellions and of savage persecutions of the Christians, whose religion was early introduced and made rapid progress. After the transfer of the seat of the empire to Constantinople, A. D. 830, the Christians of Egypt triumphed over the pagans, and for another period of 8 centuries its history presents little but theological contests, which not unfrequently broke out into civil strife. The first of these contests was the Arian controversy—Arius, who was pronounced a heretic by the council of Nice (325), being a presbyter of the church of Alexandria, while Athanasius, his orthodox opponent, was archbishop. By the emperor Constantius II. Athanasius was removed from his see and an Arian appointed in his place, while the orthodox Christians were grievously persecuted. When Julian the Apostate became emperor, the pagan mob of Alexandria rose against the Christians and murdered the Arian archbishop, and Athanasius finally regained the archiepiscopate. After his death the emperor Valens appointed an Arian to succeed him, and the persecutions of the orthodox were renewed. Theodosius I., in 379, issued stringent edicts against paganism, which still held its ground, especially in Alexandria, where it numbered among its adherents most of the learned and scientific classes and the students in the schools of philosophy. In compliance with the orders of the emperor, the pagan temples were broken into by the Christians and the statues of the deities destroyed or overthrown. The great temple of Serapis, which had been for ages the most sacred and celebrated of pagan fanes, was plundered and desecrated, and its library of 700,000 volumes despoiled by the mob. The pagans resented these outrages, and took arms in defence of their religion; but after several battles had been fought in the streets, the Christians were victorious, and the pagan leaders were driven from the city. In the reign of Theodosius II., the celebrated Cyril, archbishop of Alexandria, in 414 raised a persecution of the Jews, who were numerous and wealthy, and himself headed a mob which attacked and plundered the synagogues, and in one day expelled every Jew from the city. The pagans were next assailed, and one of their most popular teachers of philosophy, the beautiful and learned and eloquent Hypatia, daughter of Theon the mathematician, was dragged from her chariot as she passed through the street, carried into a church, and brutally murdered. At a later period, the theological controversies of Egypt culminated in the complete separation of the Coptic or Egyptian church from the orthodox, whose bishops held a council at Chalcedon in 451, and denounced the Egyptian doctrines as heretical. The bitter animosities generated by these contests alienated

the Egyptians from the government at Constantinople, so that they made no opposition when in the reign of Heraclius, in 616, the country was overrun by the forces of the Persian king Chosroes, who held it 10 years, until the outbreak of Mohammedanism so harassed the Persians that Heraclius was enabled to recover the province, only however to lose it for ever a few years later in 640, when it was conquered by the Arabs, led by Amrou the general of the caliph Omar. For more than 2 centuries after the Mohammedan conquest Egypt remained a province of the caliphate, the seat of which was transferred from Medina to Damascus, and from Damascus to Bagdad. In 868 Ahmed the viceroy threw off his allegiance to the caliph and established an independent kingdom, which lasted 87 years, when the caliphs again reduced it to subjection. After a long period of anarchy, Moez, the 4th of the Fatimite caliphs, who reigned in northern Africa, and were rivals of the caliphs of Bagdad, conquered Egypt, in 970, and building the city of Cairo, made it the seat of his government. The Fatimite dynasty ruled Egypt for 2 centuries. The most distinguished of them was Hakem (died 1021), the prophet and Messiah of the Druses, who still look for his return to earth. Adhed, the last of the Fatimites, died in 1171, and was succeeded by his vizier or prime minister, the renowned Saladin, the chivalrous and successful adversary of the crusaders. He took the title of sultan of Egypt, and at his death in 1193 was sovereign of a vast empire which his sons divided among themselves, Egypt falling to the share of Aziz. Successive invasions by the crusaders harassed Egypt for the following century, but they were all repelled by the descendants of Saladin, with signal loss to the Christians. The last and most disastrous of these attacks was made by Louis IX. of France in 1248, who landed with a large army and the flower of the French chivalry at Damietta, but after some successes was defeated and compelled to capitulate with the loss of 30,000 men. A remarkable revolution next took place in Egypt. Saladin and his successors had organized a numerous body of guards, called Mamelukes, composed exclusively of slaves of Turkish origin, brought from the countries around the Caspian sea. They gradually acquired such power and influence that at length they deposed their lawful sovereign and made one of their own number sultan. For 120 years these mercenaries controlled the destinies of Egypt, making and unmaking sultans at their pleasure. At length, at the close of the 14th century, the Circassians, from whom the ranks of the Mamelukes had long been largely recruited, overthrew the power of the Turkish Mamelukes and took the government into their own hands. Another century of anarchy succeeded, and in 1517 Egypt was conquered by the Ottoman sultan Selim I. and reduced to a Turkish province. Some of the Mameluke sultans were men of talent and energy, and under their rule Egypt was at times the centre of an extensive though fluctuating em-

pire. The arts were cultivated with some success, as is shown by the mosques and tombs of these sultans at Cairo, which justly rank among the most magnificent and elegant specimens of Saracenic architecture. Under their sway Cairo became what it has ever since remained, the chief seat of Mohammedan learning and intellectual cultivation. For 2 centuries the Turkish pashas ruled Egypt, which decayed under their rule like all the lands subjected to it. But in the 18th century the Mamelukes, who still constituted the military force of the province, gradually regained their former power to such an extent that in 1768, under the lead of their ablest and most influential chief, Ali Bey, they threw off the Turkish yoke and declared Egypt independent. At the end of 4 years, however, Ali Bey was betrayed and poisoned, and the authority of the sultan was nominally reestablished in 1772. Confusion and civil war between the different factions of the Mamelukes continued to prevail until in 1798 the invasion of Egypt by Napoleon Bonaparte united their chiefs in self-defence. Their famous cavalry made a gallant resistance to the French, but was forced to give way before the science and tactics of Europe. In the battle of the Pyramids the Mameluke army was nearly annihilated. The French conquered the whole of Egypt, and held it till 1801, when they were expelled by a British army under Generals Abercromby and Hutchinson. After the departure of the French civil war broke out afresh between the Turks and the surviving Mamelukes, which resulted, in 1805, in the elevation to the post of pasha of Mehemet Ali, an Albanian adventurer who had become leader of one of the contending factions. His authority, however, was not firmly established until after a long struggle with the Mamelukes, 500 of whom he perfidiously massacred in 1811. The dispirited survivors fled to Nubia, and since the massacre the internal tranquillity of Egypt has not been seriously disturbed. Mehemet Ali introduced great reforms in Egypt, in the system of administration, and in the organization of the army and navy. With the aid of European and American adventurers he armed and disciplined in the European manner a large native force, and created a respectable fleet. Manufactures of arms, cloths, and other important articles were introduced and sedulously fostered; the commerce of Alexandria, which had dwindled almost to nothing, was revived, and the population of the city was increased tenfold during his reign. Egypt, firmly and moderately governed, enjoyed a state of peace and good order to which it had been a stranger for centuries, and attained a commanding position among the surrounding nations. The pasha aimed at complete independence, and so great were his resources that in 1831-'32-'33 he waged a highly successful war with the Turkish sultan, conquered Syria and a great part of Asia Minor, and would have made himself master of Constantinople had not the European powers interfered to arrest the progress of his

army, and avert the overthrow of the Ottoman empire. In 1848 Mehemet Ali, at the age of 80, grew imbecile, and his son Ibrahim was invested with the pashalic. Ibrahim died at the end of 2 months, and was succeeded by his nephew Abbas, an ignorant and profligate fanatic, who was bigotedly opposed to the reforms introduced by his grandfather, and, immersed in sensual gratifications, paid no attention to the duties of his post. Mehemet Ali died, Aug. 3, 1849. Abbas died suddenly, not without suspicion of violence, in July, 1854. He was succeeded by the present ruler, Said Pasha, the 4th son of Mehemet Ali, a man of energy and intelligence, who thus far has governed wisely and humanely, and has carried out the enlightened plans of his father with some modification of certain objectionable features by which they were defaced. Under his auspices Egypt appears to be gradually advancing toward that position among the nations to which she is entitled by her inexhaustible resources and unrivalled geographical position.—For further information on Egypt generally, see CAIRO, COPTS, NILE. The subjects of HIEROGLYPHICS and the PYRAMIDS will be treated under those titles respectively, and articles upon the chief cities and personages of Egyptian history will be found under their proper heads. The discoveries of modern travellers in Egypt will be noticed under the names of the travellers. The following is a list of some of the most important works on Egypt and Egyptian subjects: Bunsen, *Aegyptens Stelle in der Weltgeschichte* (5 vols. 8vo., Hamburg and Gotha, 1845-'57; English translation, by Charles H. Cottrell, 3 vols. 8vo., London, 1848-'58 *et seq.*); Lepsius, *Denkmäler aus Aegypten und Aethiopien* (Leipzig, 1849-'58 *et seq.*), *Briefe aus Aegypten, &c.* (Berlin, 1852; English translation, London, 1855); Brugsch, *Reiseberichte aus Aegypten* (Leipzig, 1855); Uhlemann, *Handbuch der gesamten Aegyptischen Alterthumskunde* (4 vols. 8vo., Leipzig, 1857-'8); Denon, *Voyage dans la basse et la haute Égypte* (2 vols. fol., Paris, 1802), *Description de l'Égypte* (26 vols. 8vo., and 12 vols. fol. of plates, new ed. Paris, 1820-'30); Champollion, *L'Égypte sous les Pharaons* (2 vols. 8vo., Paris, 1814), *Lettres, &c.* (8vo., Paris, 1833), *Monuments de l'Égypte et de la Nubie* (folio, Paris, 1843); Mariette, *Choix de monuments et de dessins découverts ou exécutés pendant le déblaiement du Serapéum de Memphis* (4to., Paris, 1856), *Mémoires, &c.* (1856); Merriman, *L'Égypte contemporaine* (8vo., Paris, 1858); Rosellini, *Monumenti dell'Egitto e della Nubia, &c.* (8vo., folio plates, Pisa, 1840); E. W. Lane, "Manners and Customs of the Modern Egyptians" (2 vols. 8vo., 8d ed. London, 1842); Samuel Sharpe, "History of Egypt from the Earliest Times to the Conquest by the Arabs" (8vo., London, 1846); Sir J. G. Wilkinson, "Manners and Customs of the Ancient Egyptians" (5 vols. 8vo., London, 1847), "Handbook for Travellers in Egypt" (London, 1847), "A Popular Account of the Ancient Egyptians" (2 vols. 12mo., Lon-

don, 1854), Notes and Appendices to Rawlinson's "Herodotus" (London, 1858-'9); John Kenrick, "Ancient Egypt under the Pharaohs" (2 vols., London and New York, 1852). See also the travels of Savary, Sonnini, Belzoni, J. A. St. John, Harriet Martineau, Mrs. Poole, J. L. Stephens, the late Bishop Wainwright, Dr. Robinson, G. W. Curtis, Bayard Taylor, W. C. Prime, &c.

EHNINGER, JOHN WHETTON, an American artist, born in New York, July 22, 1827. He was graduated at Columbia college in 1847, and shortly after went to Europe to pursue his art studies. In 1848-'9 he was a pupil of Couture in Paris, and between 1851 and 1853 he made long visits to Düsseldorf and the chief capitals of the continent. His first oil painting, "Peter Stuyvesant" (1850), the subject of which was taken from "Knickerbocker's History of New York," was engraved by the American art union. Among his best works executed since that time are "Love me, love my Horse," "The Sword," the "Foray," the landscape of which is by Mignot, "Lady Jane Grey," and *Ars Celare Artem*, the latter now owned in Washington. He has also produced some excellent etchings and drawings in outline, pencil, and India ink. Of the former, a series illustrating Hood's "Bridge of Sighs" was published in 1849, and in 1850 another on subjects from Irving's story of "Dolph Heyliger." Of his pencil drawings the composition entitled "Christ healing the Sick," executed in 1857, and now in the possession of the Rev. Dr. Anthon of New York, is among his latest and best works. In 1858, soon after the appearance of Longfellow's "Miles Standish," he prepared a set of 8 illustrations of the poem, which were copied by the photographic process, and obtained a considerable popularity. Mr. Ehninger has of late devoted much time to perfecting a system of photographic etching.

EHRENBERG, CHRISTIAN GOTTFRIED, a German naturalist and microscopist, born at Delitzsch, April 19, 1795. He was educated at Schulpforte, till in 1815 he went to the university of Leipzig, where after a short study of theology he devoted himself to medicine. He continued his studies at Berlin, where he received the degree of M.D. in 1818, publishing on the occasion a dissertation entitled *Sylva Mycologica Berolinenses*, in which he gave an account of 248 species of cryptogamous plants found by him around Berlin, 62 of which had till then been unknown. In 1820 he was enabled to gratify a long cherished wish to travel for the purpose of scientific exploration, being appointed with his friend Hemprich by the Berlin academy of sciences to make a scientific journey in Egypt, whither Gen. Minutoli was then going for antiquarian researches. During 6 years he explored the natural history of Egypt, Nubia, and Arabia, narrowly escaping from fevers which caused the death of his companion, and returned to Berlin in 1826. He was at once appointed extraordinary professor (ordinary in 1839) of medicine in the university of Berlin,

and published a narrative of his travels and observations (Berlin, 1828). The new species which he had discovered were described in a series of *Symbolæ Physicæ Mammalium, Avium, Insectorum, et Animalium Evertibratorum*, published between 1828 and 1834. Other scientific results of his journey were contained in his works on *Die Korallenthier des Rothen Meeres* (Berlin, 1834), and *Die Akalephen des Rothen Meeres, &c.* (Berlin, 1836). In 1829 he accompanied Alexander von Humboldt in his expedition to the Ural mountains, which was prolonged to the Altai; and during this journey he began to apply himself to microscopic investigations, by which he has since made highly important discoveries, and may be said to have created a scientific knowledge of the infusoria. Among the larger works which embody the results of his researches with the microscope are the *Organisation, Systematik, und geographisches Verhältniss der Infusionsthierchen* (Berlin, 1830; additions were made in 1832, '34, and '36), and the more complete *Infusionsthierchen als vollkommene Organismen* (Leipsic, 1838), illustrated with 64 fine copperplates, which, from the elegant style in which it was issued, as well as from its scientific contents, is reckoned among the ornaments of German literature. Prior to Ehrenberg the infusoria were considered as scarcely organized, but he ascertained that they have an internal structure resembling that of the higher animals, and discovered in them muscles, intestines, teeth, different kinds of glands, eyes, and nerves. The astonishing minuteness of his observations appears from his estimate that the size of the smallest colored spots on the body of *monas termo* (the diameter of which is only $\frac{1}{3000}$ of a line) is $\frac{1}{13000}$ of a line. So great are the powers of reproduction in these animalcules, that from one individual (*hydatina senta*) he observed that 1,000,000 were produced in 10 days; on the 11th day, 4,000,000; and on the 12th day, 16,000,000. In pursuing his studies he made, partly by accident, the discovery of fossil infusoria, which form an important element in many of the strata of the earth's surface; and he showed the similarity of their phenomena in 3 different parts of the world in his *Bildung des Europäischen, Libyischen, und Uralischen Kreidefelsens und Kreidemergels aus mikroskopischen Organismen* (Berlin and Leipsic, 1839). That black earth consists of infusoria he had before stated in a special treatise. He made the same discovery in 1841 concerning the peat soil which underlies a large portion of Berlin. In his treatise on *Das Leuchten des Meeres*, which is a model of acute investigation, he attributes the appearance of shining bodies in the sea to the agency of microscopic sea animals. A similar application of his discoveries he made in his *Passat-, Staub-, und Blutregen* (Berlin, 1849), proving the existence and operation of animalcules in the atmosphere. The most important of his other works are the *Verbreitung und Einfluss des mikroskopischen Lebens in Süd- und Nord-Ame-*

rika (Berlin, 1842), the *Mikrogeologie* (Leipsic, 1854, continued in 1856 *et seq.*), and numerous papers in the "Transactions" of the Berlin academy of sciences. Many of the specifications of Ehrenberg have been questioned by other savants, but he has certainly the merit of having first proved the existence of a large class of microscopic plants and animals, and of having opened a new path in which he has now numerous followers.

EHRENBREITSTEIN, a town of Rhenish Prussia, on the right bank of the Rhine, connected by a boat bridge with Coblenz, and called Thal-Ehrenbreitstein, from its situation at the foot of a rocky height which rises 772 feet above the river; pop. about 4,000, including the garrison. On this height stands the celebrated fortress of Ehrenbreitstein, which was probably founded by the Romans under the emperor Julian, was rebuilt in the 12th century by Hermann, archbishop of Treves, and became of great strategical importance during the 30 years' war. The French under Marshal Boufflers, aided by Vauban, in vain besieged it in 1688. They assailed it again at the end of the following century, but gained possession of it (Jan. 29, 1799) only after a siege of 14 months, and after reducing the garrison to starvation. In 1801 they blew up its defences, but the reconstruction of the fortress has been accomplished by Prussia since 1815. The cost of the works on both sides of the Rhine is estimated at more than \$3,500,000. They will lodge 100,000 men, yet a garrison of 5,000 is deemed sufficient to defend them. The magazines are capable of containing provisions for 8,000 men for 10 years. Ehrenbreitstein is defended by about 400 pieces of cannon. The escarped rocks and steep slopes on 3 sides of the fortress seem impregnable. The platform on the top of the rock serves as a parade ground, and covers vast arched cisterns capable of holding a 3 years' supply of water, which is obtained from springs without the walls. The works were executed under the direction of the Prussian general Aster, who died in 1855.

EICHENDORFF, JOSEPH KARL BENEDICT, baron, a German author, born near Ratibor, Upper Silesia, March 10, 1788, died at Neisse, Nov. 26, 1857. He was descended from an ancient Catholic Moravian family, was a representative of the so-called romantic school, wrote many fine poems, translated Don Juan Manuel's *Conde Lucanor* (Berlin, 1840) and Calderon's religious plays (2 vols., Stuttgart, 1846-'55) into German, published in 1851 *Der deutsche Roman des 18. Jahrhunderts in seinem Verhältnisse zum Christenthum*, and in 1856 *Geschichte der poetischen Literatur Deutschlands*. Four editions of his poetry and of his most popular novel (*Aus dem Leben eines Taugenichts*) appeared in Berlin in the same year.

EICHHORN, JOHANN GOTTFRIED, a German oriental scholar and historian, born in Dörenzimmern, in the principality of Hohenlohe-Öhringen, Oct. 16, 1752, died in Göttingen, June

25, 1827. Having studied theology at Göttingen, in 1775 he was elected professor of the oriental languages in the university of Jena, and in 1788 was called to the same office in the university of Göttingen, where he taught with brilliant success till near his death. He first proved the extent of his learning in oriental history and literature by treatises upon the commerce of the East Indies prior to the time of Mohammed, and upon the ancient history of the Arabs. At Göttingen he devoted himself especially to biblical criticism, and published the results of his studies in his *Repertorium für biblische und morgenländische Literatur* (18 vols., Leipsic, 1777-'86), and his *Allgemeine Bibliothek der biblischen Literatur* (10 vols., 1787-1801). He was especially influential in founding the interpretation of the Scriptures on a knowledge of biblical antiquity and of oriental modes of thought by his introductions to the Old and New Testaments, and his works on the Hebrew prophets and on the Apocalypse of St. John, beside many valuable papers in periodical works. Near the close of the last century he conceived the plan of a full history of all the branches of intellectual culture in Europe since the revival of letters. To this end he associated himself with several learned writers, and composed the "History of Literature from its Origin to the most Recent Times" (6 vols., Göttingen, 1805-'12), as an introduction to the whole collection. Among his other writings, interesting both from their erudition and style, are his *Urgeschichte* (1790-'93), in which he critically examined the Mosaic records of the creation and fall, and works on the French revolution (1797), on ancient history (6 vols., 1811-'13), and on the history of the last 3 centuries (3d ed., 1817-'18).

EICHSTÄDT, a Bavarian town in the circle of Middle Franconia, on the river Altmühl, about 56 m. from Munich; pop. 6,800. The principality of Eichstädt, of which it was the capital, was dissolved Feb. 28, 1854. Eichstädt had been a bishopric until 1802, when it became a principality, a great part of which was presented in 1817 to Eugène de Beauharnais, duke of Leuchtenberg. A new bishopric, however, was established in 1821, which is suffragan to the archbishopric of Bamberg.

EIDER, a river of Denmark, rising near Kiel in the duchy of Holstein, and flowing into the North sea not far from the town of Tönningen. Its general course is N., and for a considerable distance it forms the boundary between the duchies of Schleswig and Holstein. Its total length is about 105 m., of which 70 are navigable. With the aid of a canal this river forms a means of communication between the North and Baltic seas.

EIDER DUCK (*somateria mollissima*, Linn.), one of the *fuligulinae* or sea ducks, well known for the remarkable softness of its down and the beauty of its plumage, and common, like other arctic species, to both hemispheres. The bill is elevated at the base, compressed behind the nostrils, divided in front by an acute angle of feath-

ers, flattened at the tip, which is armed with a strong, broad, and hooked nail; the lamellæ are moderate and far apart; the wings are moderate, pointed, the 1st and 2d quills longest; the tail short and wedge-shaped; tarsi more than half as long as the middle toe; the toes long, united by a full web. The head is very large, the neck short, the body bulky and much depressed; the feet are short, and placed far behind. The plumage is short, dense, soft, and blended. The bill is pale grayish yellow, iris brown, feet dingy light green with dusky webs; upper part of head bluish black, with the central part white; occiput, upper part of hind neck, and sides of neck delicate pale green; sides of head, throat, and neck white; lower neck and upper breast cream-colored or buff; rest of lower surface black, as are the tail coverts and middle of the rump; rest of upper parts white, the scapulars tinged with yellow, except the secondaries which are brownish black, and the primaries grayish brown; the length is 25 inches, the extent of wings 42, the tail $4\frac{1}{2}$, bill $2\frac{3}{4}$ inches; the weight is from $4\frac{1}{2}$ to $5\frac{1}{2}$ lbs., greatest in winter. The female differs greatly from the male, having the general plumage brown barred with black, lighter on the head and neck; secondaries and their coverts with white tips; the size is also somewhat smaller; the young in the first winter resemble the female. The eider is rarely seen south of New York; east of Boston it is more and more abundant as the latitude increases. Thousands of pairs breed and pass the summer in Labrador, where they are called sea ducks, a name also given to other species; they there begin to make their nests about the last of May, amid the grass and low bushes, and in sheltered places among the rocks; many nests are found near together, made of sea-weed, moss, and twigs, each containing from 5 to 7 eggs, about 3 inches long, of a pale olive-green color; the eggs are considered great delicacies by the fishermen. When the eggs are laid, the female plucks the down from her breast, and places it under and around them, and when incubation commences the male leaves her to take care of her eggs and herself; when she quits the nest in search of food, she pulls the down over the eggs to keep them warm; when hatched, she leads the young to the water, or carries them thither in her bill, teaches them to dive for food, and protects them from their worst enemies, the black-backed gulls; by the 1st of August old and young are moving southward. In many places the birds are not allowed quietly to hatch their eggs; the nests are robbed by man of both down and eggs, when the female seeks another male, and lays a second time with the usual quantity of down; if again disturbed, she will try a third time, the down being supplied from the breast of the male. The unnecessary destruction of the birds by the egggers of Labrador has nearly destroyed the trade, and driven them further north. The down of a nest, though bulky enough to fill a hat, when cleared of grass and twigs rarely weighs more than an ounce, though

an instance has been related in which the quantity obtained the first time from a single nest is said to have weighed $\frac{1}{2}$ lb.; when properly cleaned, it is worth from 12s. to 14s. per lb. for the English market. So highly is it prized for warmth and lightness, that in Iceland and Norway the districts resorted to by the duck are regarded as valuable property, and are strictly preserved. The Icelanders take pains to make artificial islands by cutting off projecting points from the mainland, such spots being more attractive to the birds from their seclusion than the mainland itself. Eiders fly rapidly, steadily, and generally near the water, rarely more than a mile from the shore; they are very expert divers, descending several fathoms, and remaining long under water; the food consists of crustacea, mollusks, and the roe of fishes; the gizzard is large and muscular; they are rarely seen inland, unless driven in by storms. They are shy, and difficult to kill; the flesh of the young and females is said to be well flavored, but that of the males is tough and fishy, and rarely eaten except by hungry fishermen. The common eider has been reared in captivity, becoming as gentle and tame as the domestic duck, with which it readily associates; from its eminently social disposition, it would doubtless be a valuable acquisition in a domesticated state, for its feathers and down, for its eggs, and even for its flesh.—The king eider (*S. spectabilis*, Linn.) is a handsomer bird than the preceding, and like it is an inhabitant of the higher latitudes of both continents. The bill of the male is yellowish, the upper mandible having at the base a soft, compressed, orange-colored substance, extending upon the forehead; the front is covered with short black feathers; the general shape is like that of the common eider, and the character of the plumage the same. The iris is bright yellow, feet dull orange with the webs dusky; the head is bluish gray, darkest behind; the sides of the head pale bluish green; a black spot below the eye, and 2 lines of the same color on the throat; fore neck cream-colored; the sides and posterior part, with a patch on the wings, and one on each side of the rump, white; lower plumage blackish brown; posterior part of back, scapulars, larger wing coverts, and secondaries brownish black, the latter with a greenish gloss; primaries and tail blackish brown; the size is about that of the other species. The female is quite different, having the head grayish yellow, with small brownish black lines, the scapulars with brownish red margins, the general color of the lower parts pale yellowish brown, and the quills and tail deep grayish brown; the feathers of the lower neck, breast, sides, and lower tail coverts with a centre and margin of brownish black. The king eider is not often seen in the United States, breeding further north than the common eider; its habits resemble those of the latter species; its home is the sea, the land being visited only in the breeding season; its down is valuable; the eggs are about $2\frac{1}{2}$ inches long, of a dull greenish color.

EILDON HILLS, a group of hills in the co. of Roxburgh, Scotland, consisting of 3 conical peaks, the highest of which has an elevation of about 1,350 feet. From their summits a magnificent view of the romantic border scenery of Scotland may be obtained. There is a tradition among the peasants of the neighboring country that these hills were originally one mountain, which was divided into 3 separate summits by a demon under the wizard Michael Scott.

EIMBECK, a town of Hanover, capital of the principality of Grubenhagen, 21 m. N. N. W. from Göttingen, on the Ilme; pop. 6,500. It has manufactories of woollens and linens, and several tanneries and bleacheries. Its importance has declined since its walls were destroyed by the French in 1761, but prior to that it was prominent among the military towns of the empire. It early embraced the reformation. Its beer was so celebrated that it was said that the affairs of Germany were settled by the princes over foaming draughts of it. The church containing the mausoleum of the dukes of Grubenhagen, and the castle of Rothenkirchen in the vicinity, are its finest edifices.

EINSIEDELN, or **ENSIEDLEN**, a village of Switzerland, in the canton of Schwytz, on the Sihl; pop. 6,850. It is situated 9 m. N. N. E. of the town of Schwytz, and about 3,000 feet above the level of the sea. Adjoining the village is a famous Benedictine abbey whence it derives its name. This abbey was originally founded in the 10th century, but has been since several times rebuilt. The present edifice, which dates from 1719, is in the modern Italian style, and contains a museum, a library of 26,000 volumes, and a marble chapel wherein is an image of the Virgin that attracts thither multitudes of devout Roman Catholics from many parts of Europe. The village has more than 70 inns and restaurants for their accommodation. Zwingli was once parish priest of this place.

EISENACH, a principality in the centre of Germany, formerly independent, but since 1741 united to the grand duchy of Saxe-Weimar; area, 465 sq. m.; pop. 80,600. It is bounded N. by Prussian Saxony, E. by Saxe-Gotha and Saxe-Meiningen, S. by Bavaria, and W. by Hesse-Cassel, and contains 7 cities, 8 boroughs, and 180 villages. It is traversed irregularly by mountain ranges covered with forests, and watered by the rivers Werra, Hörsel, Nesse, Ulster, and Felde. Its products are grain, flax, timber, horned cattle, sheep, copper, iron, and alum. There are also quarries of marble, important salt springs, and manufactures especially in the town of Eisenach and the village of Ruhla.—**EISENACH**, the capital of the above principality, is situated on the border of the Thuringian forest, at the confluence of the Hörsel with the Nesse, 712 feet above the sea level, 45 m. W. of Weimar, and is the chief station of the Thuringian-Saxon railway; pop. 9,980. It is enclosed by a wall, has broad streets generally paved with basalt, and several remarkable public buildings, among

which is the castle, formerly the residence of the princes of Eisenach. Its manufactures are chiefly woollen and cotton fabrics, and pipe heads of soap stone. In its environs on a lofty height is the ancient castle of Wartburg, once the residence of the landgraves of Thuringia, celebrated as the place where the Minnesingers contended for the palm of poetry, and as the asylum where Luther composed his translation of the Bible. It was in the streets of Eisenach that Luther, when 17 years of age, and a poor student, sang before the houses of the rich to gain his bread. The conferences of the German Evangelical church have been held in Eisenach since 1852, and the 12th conference of the *Zellverein* was held there in 1856.

EISLEBEN, a town of Prussian Saxony, 27 m. N. W. from Merseburg; pop. 10,800. It is noted as the place where Martin Luther was born and died. The house in which he was born no longer remains, having been burned in 1689, but that in which he died is still preserved, and has recently been converted into a school for poor children. In an upper story of the house several relics of Luther are kept, among which is the album of his friend the painter Cranach, who made the designs for his works. In the church of St. Andrew, the pulpit from which Luther preached but a few days before his death is still preserved. There are copper mines in the vicinity of the town.

EISTEDDFOD, the name of an assembly of the bards and minstrels of Wales, in the town of Caerwys in Flintshire, for the purpose of musical and poetical contests. After long disuse, they are now held at regular intervals.

EJECTMENT (Lat. *ejectio firmæ*; Fr. *éjection de firme*), an action for the recovery of the possession of lands, but now used both in England and the United States for the trial of title. The peculiarity of this action has been referred to in the article **DISSEISIN**. As it retains scarcely any thing of its original form and uses, the history of the action is matter rather of curious learning than of practical importance. Yet it is well worthy of study as perhaps the most remarkable precedent of the adaptation of form to new exigencies to be found in the English law. A lucid exposition of the origin and gradual modification of the action will be found in Blackstone's "Commentaries," vol. iii. pp. 199-205.

EKATERINBURG, **EKATERINBOURG**, or **YEKATERINBOURG**, literally Catharine's castle, the capital of the Russian mining district of the Ural, in the government of Perm, situated about 50 m. from the European frontier, on the Asiatic side of the Ural mountains; lat. 56° 50' 14" N., long. 60° 34' 44" E.; pop. in 1851, 15,528. Ekaterinburg is built on each side of the river Isht. On the S. E. side is an extensive plain, upon which are the government buildings connected with the working of the precious metals and gems, as also a public square or market place. On the opposite side are spacious streets and elegant houses of the merchants and mine proprie-

tors. Some of these are upon the summits of hills, and those upon the north side of the town overlook a beautiful lake, which extends several miles in a westerly direction until hid in the Isetskoi woods. From the lake is a fine view of the towers, spires, and domes of the 8 churches, the monastery and the convent seen above the numerous other public and private buildings; while overtopping and behind all is a rocky mount clothed with dark green foliage, upon the summit of which is the observatory used for magnetic and other scientific observations. The numerous costly edifices are mostly built of brick and covered with cement. Some private houses are described as well built and beautifully decorated, and furnished with much luxury and comfort. The town owes its importance to the numerous rich mines in its vicinity. The mineral productions are gold, copper, iron, platinum, and precious stones. The iron mines near here are of vast extent and importance, and some of their products, in the form of sheet iron, find their way even to the United States. Platinum is found in considerable quantities, and this is the most important region on the globe for the production of this metal. Among the precious stones worked at the great lapidary establishments of Ekaterinburg are noted particularly the jaspers, malachites, topaz, emeralds, beryls, chrysoberyls, aquamarine, tourmalines of different colors, amethysts, &c., some of which are brought great distances from eastern Siberia. The jaspers, malachites, and porphyries also, are made into tables of great magnificence and immense value, some inlaid with stones of different colors in imitation of birds, flowers, and foliage. The jasper vases ornamented with delicate carvings of foliage are described as objects of great beauty, executed with extraordinary skill and taste by workmen whose wages are somewhat less than a dollar per month, with 2 *poods* (72 lbs.) of rye flour. Meat they are supposed never to eat. At the great establishment called the Granilnoi Fabric, which belongs to the Russian government, this work is extensively prosecuted, and the columns, pedestals, tables, vases, and numerous smaller articles, are said to be unrivalled in workmanship, either in ancient or modern times. All the precious stones found in Siberia are the property of the czar, and the most valuable of these are sent to the imperial palace at St. Petersburg. The government also owns different iron works in this region, in which are constructed heavy guns and other munitions of war. The chief of the Ural, or principal officer of the mining direction, appointed by the government, is a general of artillery; and another general of artillery is appointed by the minister of war to reside at Ekaterinburg, with especial charge to inspect and supervise the construction of all the guns made in the mining districts of the Ural. At Ekaterinburg are machine shops of great extent belonging to the government, in which the machinery is made for the mint and other public works, the iron employed being of

the highly prized qualities so well known on this side of the Atlantic, as obtained from the Ural mines and furnaces. Machine works have also been established at Ekaterinburg within a few years past by private individuals; also an extensive manufactory of stearine. (See Atkinson's "Siberia," London, 1858.)

EKATERINOSLAV, IEKATERINOSLAV, or YEKATERINOSLAV, a government of European Russia, between lat. 47° and 49° 20' N., and long. 83° 30' and 39° 40' E., bounded E. by the territory of the Don Cossacks, S. by the sea of Azof and Taurida, W. by the government of Cherson, and N. by those of Pultowa and Kharkov, and comprising also the district of Taganrog and the territory of the Azovian Cossacks, separated from the rest of the government by the country of the Don Cossacks; area, 25,523 sq. m.; pop. in 1851, 902,369. The Dnieper intersects and divides it into 2 unequal portions. The larger of these divisions, situated E. of that river, is mostly an open steppe, destitute of timber, and adapted only to pasturage; but the smaller, or W. section, is fertile and undulating. The climate is mild and healthful. The principal vegetable productions are wheat, barley, oats, hemp, flax, and fruit. The chief wealth of the inhabitants, however, consists of horses, horned cattle, sheep, and swine. The rivers abound in fish. The most valuable minerals are granite, limestone, chalk, and salt. There is little manufacturing industry, but a great many distilleries, where large quantities of brandy are made. The population consists chiefly of Russians and Cossacks, but Servians, Wallachians, Greeks, Tartars, Turks, Persians, and German colonists are also found. The houses of the poorer classes are generally constructed of clay and thatched with rushes. The government is divided into 7 circles.—EKATERINOSLAV, the capital of the government, is on the right bank of the Dnieper; pop. about 13,000. This town was founded in 1784. The streets are broad and regular. The principal edifices are the churches, gymnasium, ecclesiastical seminary, hospitals, law courts, public offices, barracks, and bazaars. There are manufactories of cloth and silk stockings, and a large annual wool fair. It is the seat of an archbishop.

EKRON, the most northern and important of the 5 royal Philistine cities, assigned in the distribution of territory to Judah. The ark was taken to Ekron after its capture by the Philistines. Beelzebub was called the god of Ekron, and was here worshipped, and the prophets made this city the burden of some of their most violent denunciations. It is supposed by Dr. Robinson that the modern Moslem village of Akir, 5 m. S. of Ramleh, occupies the site of the ancient Ekron.

EL, or AL, the Arabic definite article, often making one word with the noun which follows it; thus, *Alkoran*, the Koran. Its other forms are *il*, *ul*, and *ol*. Many words in English and other European languages beginning with *el* or *al* are from the Arabic, as *almanac*, *alcohol*

EL DORADO. Orellana, the lieutenant of Pizarro, being sent on an expedition from the sources of the Amazon to its mouth, pretended to have discovered in the interior of the continent, between this river and the Orinoco, a country surpassing even Peru in the abundance of its precious minerals and metals. To this he gave the name of El Dorado, the golden region, and to its capital the name of Manoa. For a long time afterward this fabulous region grew more and more famous from the exaggerated accounts that were published, and from the explorations that were undertaken in search of it, and it was not until the commencement of the last century that its existence was generally discredited. Even as late as 1780 a large party of Spaniards were lost in one of these expeditions. The word, except as now applied from the love of hyperbole to several villages in the western states, and to a county in California, is only used poetically to express a region overflowing with riches.

EL DORADO, a N. E. co. of California, bounded E. by Utah, and N. by American river, by the S. fork of which, and by Carson's and Walker's rivers, it is also drained; area, 2,050 sq. m.; pop. in 1856 estimated at 55,980. It is crossed by the Sierra Nevada. In 1856 it produced 17,280 bushels of wheat, 27,600 of barley, 26,400 of oats, 300 of potatoes, and 1,628 tons of hay. Not more than 5,000 acres were under cultivation, over $\frac{1}{2}$ of the county consisting of mineral land, which is among the most valuable in the state, and on which, beside gold, are found rich copper ore and excellent marble. In 1856 there were 17 quartz mills in operation, 44 saw mills, 1 grist mill, 10 brick kilns, 8 tanneries, and 6 breweries. Capital, Placerville.

EL PASO, a N. W. co. of Texas, bounded N. by New Mexico, and W. by the Rio Grande; area, 10,300 sq. m.; pop. in 1858, 3,078, all of whom were returned as free whites. The surface is mountainous, and about $\frac{1}{2}$ is covered with timber. The soil of the valleys is rich and suitable for wheat and Indian corn. Coal is found in abundance. Value of real estate in 1857, \$103,140. Formed from Bexar co. in 1850. Capital, El Paso.

EL PASO, or **EL PASO DEL NORTE**, a line of settlements in the N. E. corner of Chihuahua, Mexico, opposite the town of Franklin in Texas. They are situated in a narrow valley extending 9 or 10 m. along the right bank of the Rio Grande, which is here from 300 to 600 feet wide. The soil of the valley is remarkably rich, and suitable for oats, wheat, and maize; the grape also grows here in great perfection. The chief manufactures of the place are a species of weak wine and brandy, called by American traders "Pass wine" and "Pass whiskey." The inhabitants of these settlements are usually of mixed races, few of them being free from a tinge of Indian blood. They are not without wealth, but never use the means at their command to supply themselves with articles of comfort or luxury which in most civilized communities are deem-

ed indispensable. Glazed windows, for example, are unknown; knives and forks are not used; and even the houses of the rich contain neither chairs nor tables. Their dwellings are built of sun-dried bricks, with earthen floors, and are usually but one story high. The parish church, the plaza, and the more pretentious of the private residences, are situated in the northern part of the valley, just below a gorge or pass in the mountains. This portion of the settlement is probably best entitled to be called the town of El Paso. It is about 350 m. S. by W. from Santa Fé, 600 m. in a direct line E. from the Pacific, and 1,800 m. from Washington; lat. $31^{\circ} 42' N.$, long. $106^{\circ} 40' W.$; pop. about 5,000. It is the principal thoroughfare between New Mexico, Chihuahua, and the Mexican states further south, and is an important station on the southern overland route to California. Its name, signifying "the pass," is probably derived from the passage of the Rio Grande through the mountains.

ELAGABALUS, **VARIUS AVITUS BASSILASTA**, a Roman emperor, son of the senator Varius Marcellus and Julia Sœmias, and cousin of Caracalla, born at Emesa, in Syria, about A. D. 205, died in Rome in 222. He has been called the Sardanapalus of Rome. While yet a boy he was made priest of Elagabalus, the Phœnician sun god, in his native city; and the Roman soldiers who used to resort to the magnificent ceremonies of the temple there, beholding the elegant dress and figure of the young pontiff, thought they recognized in him the features of Caracalla. His artful grandmother was willing to advance his fortune at the expense of her daughter's reputation, and spread a report that he was the offspring of an intrigue between her and the murdered emperor. The army, disgusted with the parsimony and rigid discipline of Macrinus, was disposed to admit his pretensions. Elagabalus, as he was called from his sacred profession, took the name of Antoninus, was received with enthusiasm by the troops of Emesa, and declared emperor under the name of Marcus Aurelius Antoninus (218). Macrinus sent detachments of his army from Antioch to crush the rebellion, but the legions murdered their commanders and joined the enemy. At length he himself marched forth to meet the pretender, and his prætorian guards broke the rebel ranks. But Elagabalus, for the only time in his life recklessly heroic, charging at the head of his best troops, renewed the battle with such vigor that Macrinus fled, and the prætorians surrendered. Macrinus was soon after captured and put to death, and the Roman senate recognized the victorious boy as emperor. He began his march from Syria to Italy, spent a winter at Nicomedia, and in the next summer made his entry into the capital in all the state of an oriental monarch. He quickly displayed not less the despotic humor of a passionate old man than the fantastic caprices of a spoiled child. His elevation he thought to be due to the power of the sun, which he worshipped in the form of a black conical

stone, and the senators of Rome were obliged to see their hills covered with altars and their streets filled with processions in honor of the god of Emesa. Mount Palatine became the seat of a magnificent temple, where lascivious dances were performed by Syrian damsels. The Quirinal was occupied by a senate of women, who gravely discussed matters of toilet and ceremonial. In a mystical fancy about the sun and moon, he married the Carthaginian priestess of the moon, which was adored in Africa under the name of Astarte. He abandoned himself to the wildest pleasures, but neither a rapid succession of wives, nor a long train of concubines, nor the art of his cooks, could satisfy his passions, or save him from satiety. Wearied at length with playing the part of a man, he declared publicly that he was a woman, wished to be dressed like the empress, chose a husband, and worked upon lace. His cruelties were as great and as fantastic as his follies. Having at one time invited the patricians of Rome to a dinner, in the midst of the repast he opened the doors and let in upon them several furious tigers and bears. The patience of the populace and soldiers being exhausted by his vices and tyranny, a sedition was about to break out, when Elagabalus was induced to adopt as his colleague his cousin Alexander Severus. Alexander cherished the rigid manners and primitive usages of Rome, and quickly became the favorite of the army. When Elagabalus sought to withdraw from him the power which he had granted, or even to compass his death, the prætorians broke out in mutiny and killed the emperor and his mother, and threw their bodies into the Tiber.

ELAND, a name applied by the colonists of the cape of Good Hope to the impoofo (*boselaphus oreas*, H. Smith), an antelopean ruminant, resembling the bovine group in stature, shape, dewlap, and high shoulders. The general color above is a grayish yellow, with rusty and purplish shades shining through it; the lower parts cream yellow; the forehead with long, stiff, yellowish brown hairs; face brownish red, chin white, eyes chestnut; a slight brownish yellow mane, along the back becoming reddish brown; muzzle black; hoofs brownish black, edged above with brownish red hair; the tail is brownish red, with a tuft of yellowish brown; the mane of the dewlap is yellowish brown, pencilled with brownish red. This is the color of the male, which has a small head, a neck tapering above, but bulky toward the chest; the body is thick and heavy; the limbs elegant and slender; the eyes are full and soft, and the expression of the face is gentle and ovine; the horns slope slightly back from the crown, being very thick at the base, with 2 spiral turns having an obtuse ridge, and the upper $\frac{1}{2}$ straight, tapering to a point; the ears are long, narrow, and pointed, hairy on both sides; the hair is rather thin, except on the neck, mane, dewlap, and tuft of tail. The length from nose to base of tail is about 10 $\frac{1}{2}$ feet, the head being

17 inches; the horns are nearly 3 feet long; the height at the shoulder is 5 $\frac{1}{2}$ feet, and at the crupper 2 inches less; the length of the tail 2 $\frac{1}{2}$ feet, and of the dewlap at its base 20 inches. The female is of a pale sienna yellow, deadened with pale brown above; below dirty white, with a cream-yellow tinge; the figure is more delicate and elegant than that of the male, the limbs are more slender, the mane is shorter, the dewlap narrower, the tail less tufted; and the horns are straight, slender, somewhat spiral at the base, with a rudimentary ridge on the spire. The young are of a tint between reddish orange and yellowish brown. This is probably the largest of the antelopes, equalling the horse in height, and weighing from 7 to 10 cwt. It ranges the borders of the great Kalahari desert in herds varying from 10 to 100; rare at present within the limits of Cape Colony, it was found in abundance in the wooded districts of the interior by R. Gordon Cumming. The flesh is most excellent, and is greatly esteemed. When young and not over-fed the eland is not easily overtaken by the cape horses; but in good pastures it grows so fat that it is easily run down; it is said that when pursued it invariably, if it can do so, runs against the wind, which gives it an advantage in outrunning a horse. The hide is very tough, and much prized for shoes and traces. Like other antelopes, it seems to be independent of water, frequenting the most desert localities far from streams and rivers; except in the breeding season and when pursued, the males generally keep in groups apart from the females. Another species of the genus *boselaphus* is the *B. canna* (H. Smith), called bastard eland by the colonists to distinguish it from the preceding species; it is smaller than the eland, of a dark brownish gray color, with a white space between the fore legs. The name of eland, or elk, is improperly applied to this as well as to several other deer and antelopes, by the Dutch colonists of Africa and the Indian archipelago, and apparently indiscriminately to any hollow-horned ruminant of large size; the animal called eland by recent travellers and hunters in south Africa is in most cases the first described species, and probably sometimes the second, as both are found in the same districts, though the herds do not intermingle. These animals are gentle and readily domesticated; but though strong, the shoulders do not possess that solidity which renders common domesticated cattle so valuable to the agriculturist. The late earl of Derby in 1842 received at his extensive menagerie at Knowsley Hall 2 males and a female eland, the first brought alive to Europe; the female produced several calves, but the whole stock died from improper pasturage except one female born in 1846. In 1851 a fresh supply was received from the cape of Good Hope, which he bequeathed the same year to the zoological society. This herd, 2 males and 3 females, rapidly increased, and several were distributed by sale to different parts of England, whose uncultivated lands re-

resemble the park-like country of the African home of the animal. Lord Hill, of Hawkstone, Shropshire, first attempted their naturalization in his extensive park, and on Jan. 7, 1859, killed the first eland for the table which had been bred in England; the animal, 5 years old, weighed when he fell 1,176 lbs., "huge as a short-horn, but with bone not half the size." Choice parts of the animal were served at the tables of Queen Victoria and the French emperor, and before Prof. Owen and members of the zoological society; it was found to resemble beef, with a venison flavor, with a fineness of fibre and a delicacy of fat placing it high on the list of choice and nutritious articles of food. It seems probable that this animal will be extensively raised in England, and add an important item to the national bill of fare. It is much to be regretted that we have no place in the United States where similar experiments in introducing new animals may be prosecuted on a large scale.

ELASTIC CURVE, the curve assumed by a straight spring of uniform thickness when the ends are brought forcibly together. It embraces a variety of appearances, simple waves, overlapping waves, a figure of eight, retrograde loops or kinks, ordinary loops, and the circle. The fundamental law or equation of the curve is that the curvature of each point is directly proportional to its distance from a certain straight line on which the curvature is zero; so that when the curve crosses this line it reverses the direction of its curvature.

ELASTICITY (Gr. *ελαυνω*, to drive, to draw). When by the application of an external force the particles of a body are disturbed from the state of equilibrium in which they were held, and a change of form is thereby induced in the body, the tendency of the particles to regain their former state and restore the original form is termed elasticity. The force is more nearly perfect according as the time required to regain the primitive form, after the cessation of the disturbing force, approaches that expended in producing the change. The air and gases exhibit the property more perfectly than any other substances; but no bodies are altogether deficient in it. A ball of glass, ivory, steel, or other hard material, let fall upon a smooth hard surface, rebounds from the tendency of the particles to return to the position among themselves from which they have been forced by the blow. If the hard surface be covered with a thin coating of some viscid substance, or of oil, the impression left upon this indicates a flattening of the ball, and this is found to be greater according to the height of the fall. Fluids formerly thought to be incompressible, and consequently inelastic, have been proved by the experiments of Oersted to be compressible in proportion to the force exerted, and when relieved of pressure they returned immediately to their former bulk; hence they may be regarded as fulfilling the requirements of perfect elasticity, though only to a very slight extent. The elasticity of the soft metal lead is shown by the ten-

dency of a long wire made of it, when suspended at one end and twisted, to uncoil itself and return to its former position. A thread of clay, made by forcing the soft substance through a small hole, manifests the same property. In these and many other instances the force exerted by the particles to regain their former position of equilibrium carries them back to this point, and the force not being expended the motion is continued in the same direction till the resistance becomes too great, and thus the particles are drawn alternately in one and the other direction with constantly diminishing force, producing a series of vibrations; thus musical sounds are produced, the pitch depending upon the greater or less rapidity of the vibrations. By the application of too great force, or by too great strain, the particles of a solid body may be displaced and find their equilibrium in a new arrangement. This may occur with a visible separation of the particles, as in a breaking apart of the body; or it may be made apparent by the manifest indisposition of the body to change from its new state. A wire or metallic bar thus bent beyond its limit of elasticity is said to have "taken a set." The amount of elasticity in bodies, or the force they will resist without permanent alteration of structure, may be expressed by the number of pounds weight to the square inch they will bear without being crushed, or, as proposed by Dr. Thomas Young, "by the weight of a certain column of the same substance, which may be denominated the *modulus* of its elasticity, and of which the weight is such that any addition to it would increase it in the same proportion as the weight added would shorten by its pressure a portion of the substance of equal diameter. . . . The height of the modulus is the same for the same substance, whatever its breadth and thickness may be; for atmospheric air it is about 5 miles, and for steel nearly 1,500." This modulus or coefficient of elasticity has been determined by experiment for a considerable number of substances. It is an important element in the physical properties of bodies, and must be duly considered in investigating the strength of materials, the sciences of hydrodynamics, pneumatics, &c.

ELATERIUM (Gr. *ελαυνω*, to drive), a drastic purgative medicine, prepared from the juice of the *momordica elaterium*, or the wild or squinting cucumber. Hippocrates applied the name generally to any active purge. It is uncertain whether the name was given to the plant from the curious property belonging to the fruit of separating when ripe from the vine and discharging its juice and seeds through an opening at the base, where it was attached to the foot stalk, or from the action of the medicine prepared from it upon the bowels. This medicine is a very light, pulverulent, and pale yellowish green sediment deposited from the juice. The quantity is very small, only 6 grains being obtained by Clutterbuck from 40 cucumbers. A dose of $\frac{1}{4}$ of a grain of the genuine article,

however, purges violently; larger quantities excite nausea and vomiting. In dropsy it is highly recommended from its tendency to produce copious liquid discharges. The plant is largely cultivated in the south of Europe and in some parts of England. The stem has been seen 4 inches wide, with a thickness of only half an inch. When the fruit separates from the stem, the juice is said to be thrown sometimes a distance of 20 yards. One incurs some risk of injury to the eyes in walking among the vines at the season of maturity of the fruit. The juice thus naturally expelled is inferior in quality to that afterward expressed from the fruit. From a bushel weighing about 40 lbs., and worth from 7s. to 10s. sterling, about half an ounce of the medicine is obtained; but if the expression is carried too far, the product is of inferior quality.—See article by Mr. Jacob Bell in "Pharmaceutical Journal and Transactions," Oct. 1850.

ELATH (in Josephus *Ailana*, in Roman geography *Elane*, now *Ailah*), a seaport of Idumea, of great celebrity, lying on the shore of the eastern or Elanitic gulf of the Red sea, now called the gulf of Akabah. It was a part of David's conquest from the Edomites; was a place of great importance in Solomon's time, as the port in which he built and fitted out his ships for importing gold from Ophir; was captured by the revolted Edomites in the reign of Joram, after having been in the possession of the Israelites 150 years; was retaken by Uzziah, who fortified it anew, peopled it with his own subjects, and restored the trade to Ophir; was afterward taken by Resin, king of Damascus, who in his turn was deprived of it by Tiglath-Pileser, king of Assyria, from whose time it was never recovered by the Jews. Elath adjoined Ezion-Geber; and Akabah now occupies the site of one or both of these ancient towns.

ELBA, the *Ilva* of the Romans and the *Æthalia* of the Greeks, an island in the Mediterranean, belonging to Tuscany, from the coast of which it is separated by the strait of Piombino; length about 18 m., and greatest breadth 12 m.; area, about 97 sq. m.; pop. in 1858, 22,026. Its outline is irregular, the mountains which traverse the island rising in some parts to a height of above 8,000 feet, and being indented by deep gulfs and inlets, so that its breadth in some places does not exceed 3 m. The soil is fertile, but only a small portion of it is under tillage. The valleys abound with fruit trees, but they are not well cultivated, and the fruits are of inferior quality, excepting oranges. Among the annual products of the island and its waters are about 1,700,000 gallons of red and white wine, 4,000,000 lbs. of marine salt, 5,000 to 6,000 tons of tunnies, sardines, anchovies, and other fish, and 18,000 tons of minerals, chiefly iron, for which the island has always been celebrated. The iron is found in a mountain near Rio, on the E. coast, about 2 m. in circumference, 500 feet high, and yielding from 50 to 75 per cent. pure metal. About 800 persons

are employed in the mines. The quarries of granite in the S. W. part of the island appear also to have been extensively worked by the Romans. The commercial relations of the island are almost confined to Leghorn and Marseilles. The imports consist chiefly of grain, cattle, cheese, and manufactured articles, and the exports of the above named and a few other articles. Ancient ruins are still visible in various parts of the island. During the middle ages it was ruled by various Italian princes and chiefs. In 1548 Charles V. ceded the territory of Porto Ferrajo to Tuscany. Afterward the island was successively governed by Spain, Naples, and the lords of Piombino. From July, 1796, to April, 1797, it was in the possession of the British. It was then ceded to France, and united with the new kingdom of Etruria. The treaty of Paris in 1814 erected Elba into a sovereignty for Napoleon I., who resided there from May 4, 1814, to Feb. 26, 1815, when he embarked from the island with about 1,000 men for France, landing at Cannes, and marching triumphantly to Paris. During his brief sovereignty Napoleon introduced many improvements, and caused a good road to be built uniting Porto Carrajo with Porto Longone, a small fortress and harbor on the E. coast. In 1815 Elba reverted to the grand duke of Tuscany, and its affairs are now administered by a civil and military governor (in 1859 Col. Edoardo Facdonelle), who resides in Porto Ferrajo.

ELBE (anc. *Albis*), a large and commercially important river of Germany, rising in the Riesengebirge of Bohemia, near the frontier of Prussian Silesia, and passing into the North sea between Holstein and Hanover, through Austria, Saxony, Prussia, Anhalt-Dessau, Hanover, Mecklenburg, and Hamburg. It is about 650 m. long; is known at its source as the Labe; originates in a number of springs on the western slope of the Schnee-Koppe (snow summit), one of the peaks of the Riesengebirge; runs mainly in a N. W. course; is navigable from its confluence with the Moldau, and has but a very slight inclination, its bed, 40 m. from its sources, being but 658 feet above the sea. Its chief affluents are: on the right, the Iser, Black Elster, Havel, and Spree; on the left, the Moldau, Eger, Mulde, Saale, Ohre, Jetze, Ilmenau, and Oste. Josephstadt, Königgrätz, Leitmeritz, in Bohemia; Pirna, Dresden, Meissen, in Saxony; Torgau, Wittenberg, Magdeburg, in Prussia; Lauenburg, Hamburg, and Altona, are the chief places situated upon its banks. Its channel, between Hamburg and the sea, will admit of the passage of vessels drawing 14 feet water, at all times, but is much encumbered with sand bars and shoals. By means of its own waters and those of the numerous canals branching from it, the Elbe places all N. W. and central Germany in connection with the seaboard. Wood, stones, fruits, and earthenware are the chief articles of export, which are exchanged for corn, salt, and colonial produce. Its navigation was in former times much com-

plicated by the regulations of the states through which it runs. Since 1821 these have been simplified, and the entire river is now open to vessels of all the adjacent countries. Austria relinquished the Bohemian Elbe dues in 1852. In 1855 Hanover abolished the Elbe dues levied at Stade for all ships and goods entering Harburg seaward, and various conferences have since been held for the purpose of bringing about a total abolition of the dues. The Hanoverian chamber in 1858 voted a grant of money for the improvement of the navigation. There are steamboats on the Elbe between Magdeburg and Hamburg, and between Dresden and the source of the river in Bohemia.

ELBERFELD, an important manufacturing town of Rhenish Prussia, adjoining Barmen, 15 m. E. from Düsseldorf, and connected by railway with that and most other Prussian towns; pop. in 1855, 41,080. The river Wupper, which flows through the town, presents advantages for bleaching. Linen bleacheries were in operation here as early as the 16th century. Manufactories of linen, woollen, cotton, silks, lace, ribbons, &c., were gradually established, and have since the 18th century attained to a high degree of perfection. The dyeing of Turkey red, which was first attempted in 1780, is another prominent pursuit at Elberfeld. Large quantities of yarn are annually sent here from Great Britain and other countries to be dyed. The annual value of the goods manufactured in Elberfeld exceeds \$11,000,000. The Rhenish East India company and a company for working mines in Mexico had their seat here for a number of years. Elberfeld is rich in charitable and educational institutions, among which are a gymnasium, an industrial school, and a school in which the higher branches of weaving are taught.

ELBERT, a N. E. co. of Ga., separated from S. Carolina by Savannah river, bounded S. and W. by Broad river, and drained by several small creeks; area, 514 sq. m.; pop. in 1852, 13,158, of whom 6,446 were slaves. The surface is hilly, and the soil, particularly near the rivers, is fertile. The productions in 1850 were 614,066 bushels of Indian corn, 65,183 of oats, 64,777 of sweet potatoes, and 8,565 bales of cotton. There were a number of mills and factories, 20 churches, and 1,202 pupils attending public schools. Near the Savannah river are several remarkable artificial mounds, one of which is 40 or 50 feet high and has a large cedar growing on its summit. The county was named in honor of Samuel Elbert, formerly governor of the state. Value of real estate in 1856, \$1,506,244. Capital, Elberton.

ELBERT, SAMUEL, an American officer of the revolution, born in South Carolina in 1743, died in Savannah, Ga., Nov. 2, 1788. He was engaged in commercial pursuits in Savannah, where he became a member of the general committee of safety, and in Feb. 1776, received a commission as lieutenant-colonel from the assembly of Georgia. He was promoted to the rank of colonel in the same year; led an un-

successful expedition against the British in East Florida in the summer and autumn of 1777; was actively engaged near Savannah, and captured Oglethorpe's fort at Frederica, in 1778; and distinguished himself during Campbell's attack upon Savannah in Dec. 1778. He commanded a brigade at the battle of Brier Creek, where he was taken prisoner, March 3, 1779; and after being exchanged he went to the north, joined the forces under Washington, and took part in the battle of Yorktown. At the close of the war he received the commission of major-general, and in 1785 he was elected governor of Georgia.

ELBEUF, or ELBŒUF, a French town, in the department of Seine-Inférieure, on the left bank of the Seine, 4 m. distant from the Tourville station of the Paris and Rouen railway; distance from Paris 78 m., and from Rouen 18 m.; pop. about 19,000, exclusive of about 12,000 workmen from adjoining villages employed in the factories. Almost from the foundation of the town in the 9th century the inhabitants displayed great skill and industry in the manufacture first of tapestry and afterward of woollen cloth. Colbert's enactments in 1667 promoted the prosperity of the town, which was interrupted, however, by the revocation of the edict of Nantes, when many of the manufacturers emigrated and settled in Leyden, Norwich, and Leicester. The industry of the place did not fully recover from this shock and from the competition of Belgium until 1815. The annual products, which then amounted only to about 25,000 pieces (of 60 yards each), comprised in 1858 about 70,000 pieces. There are 200 factories, mostly worked by steam power, 25 dyeing establishments, and 10 depots of wool, of which about 6,000,000 lbs. are annually required. The annual aggregate value of the total production is estimated at \$10,000,000. The description of goods produced includes double-twilled and water-proof cloths, zephyrs, fancy cloths, billiard table cloth, and flannel. Nearly 40 establishments received medals at the Paris industrial exhibition of 1855. There are 2 annual fairs, deriving importance from the sale of cloth, the extensive trade in wool, and also in cattle, chinaware, and hosiery. Elbeuf contains 2 Gothic churches, courts of law, and various schools and charitable institutions.

ELBING, a seaport town of eastern Prussia, on a river of the same name, and on the Berlin and Königsberg railway, 84 m. E. S. E. from Dantzig; pop. 24,000. It is composed of the old and new towns and several suburbs, is surrounded by ruinous walls and ramparts, and contains 8 Protestant churches, 1 Catholic and 1 Mennonite church, and 1 synagogue. Among its public buildings the most remarkable is the church of Notre Dame, a structure of the 14th century. A college founded here in 1536 has a library of 18,000 volumes; and among its benevolent establishments are several endowed by Mr. Richard Cowle, a wealthy Englishman, who took up his residence in Elbing in 1810 and

died in Dantzic in 1821. Elbing has manufactories of sugar, potash, tobacco, soap, chicory, vitriol, leather, and woollen fabrics. Its maritime trade is very active, its exports being its own manufactures, and its imports grain and wine. This place owes its origin to commercial establishments founded by colonists from Bremen and Lübeck in the 13th century, under the protection of a fortress constructed by knights of the Teutonic order. It was early admitted into the Hanseatic league, placed itself under the protection of Poland about the middle of the 15th century, and in 1772 was annexed to the Prussian dominions.

ELCESAITES, a sect of Asiatic Gnostics, founded in the reign of Trajan, a branch of the Jewish Essenes, kindred to and finally confounded with the Ebionites. A Jew by the name of Elxai or Elcesai is supposed to have been their founder. Their most distinctive tenet was that man is but a mass of matter in which the divine power is concealed. They were tenacious of their oaths, favored early marriages, and rejected the Pentateuch and the epistles of Paul.

ELCHE (anc. *Ilici*), a town of Spain, province of Valencia, 13 m. S. W. from Alicante, 8 m. W. from the Mediterranean; pop. 22,800. It is girdled on every side by forests of palm trees, and has been named the city of palms. The chief industry of the place is employed in the culture and exportation of dates, which are inferior to those of Barbary.

ELCHINGEN, a Benedictine abbey of mediæval celebrity, founded in 1128 upon a steep mountain in Bavaria, 7 m. from Ulm. Amid the massive buildings which composed this abbey, the church, which was destroyed by lightning in 1773, was especially distinguished. In its place another has been constructed in an even more ancient style of architecture. The abbey of Elchingen gives its name to 2 villages situated 8 m. apart upon opposite sides of the mountain. The battle of Elchingen, Oct. 14, 1805, was one of the most brilliant episodes in the Austerlitz campaign of Napoleon, and gained for Marshal Ney the title of duke of Elchingen.

ELDER (*sambucus Canadensis*, Linn.), a showy shrub, well known from its numerous flat cymes of white flowers appearing in June, to be succeeded by heavy black-purple, crimson-juiced berries in August, and overtopping the wild reeds and bushes on the borders of fields. On account of its long and spreading roots it is sometimes troublesome to the farmer. A wholesome sudorific decoction is prepared from its flowers, which are carefully gathered and dried for the purpose; the fruit is much esteemed by some in the manufacture of a sort of wine, while the pith of the stem furnishes excellent pith balls for electrical experiments. There is another species (*S. pubens*, Michaux), which has a scarlet fruit, fully ripe at the time the former is in blossom. The flowers of this are handsome, of a greenish or purplish white, borne in thyrses-like spikes. The plant is well worthy of cultivation where it is not found growing wild.

ELDER, an overseer, ruler, or leader. The reverence paid to the aged in early times was doubtless the origin of this title, it being used as a name of office both among Jews and Christians. Macknight thinks it was applied in the apostolic age to all, whether old or young, who exercised any sacred office in the Christian church. Elders or seniors, in the ancient Jewish polity, were persons noted for their age, experience, and wisdom; of this sort were the 70 whom Moses associated with himself in the government of Israel, and such also were those who afterward held the first rank in the synagogue as presidents. Elders, in church history, were originally those who held the first place in the assemblies of the primitive Christians. The word *presbyter* is sometimes used in the New Testament in this signification, and as interchangeable with *ἐπισκοπος*; and hence the first meetings of Christian ministers were called *presbyteria*, or assemblies of elders. Elder and elders, with the Baptists, are terms used to designate ministers of the gospel generally. With the Presbyterians they are the officers who, in conjunction with the ministers and deacons, compose the church sessions, representing the church itself, conducting its discipline, and aiding in the promotion of the interests of religion. They are chosen from among the people, usually for life; are generally set apart to their office with some public ceremony; and their number is different in different churches.—It has long been a matter of dispute whether there are any such officers as lay elders mentioned in Scripture. On the one side, it is said that these officers are nowhere mentioned as being alone or single, but always as being many in every congregation; that they are mentioned separately from the brethren; and that their office is described as being distinct from that of preaching, he that ruleth being expressly distinguished from him that exhorteth or teacheth. On the other side, it is contended that the distinction alluded to does not refer to different orders of officers, but only to the degree of diligence, faithfulness, and laboriousness with which they discharge their duties and fulfil their ministerial work; and that the emphasis in such passages as 1 Timothy, v. 17, is to be laid on the word "labor," not on the word "especially," as though the latter were intended to distinguish between two different classes of elders, one superior, in some respects, to the other.

ELDON, JOHN SCOTT, earl of, lord chancellor of England, born in Newcastle-upon-Tyne, June 4, 1751, died in London, Jan. 18, 1838. His father was a man of respectable fortune, engaged in the coal trade. John was taught in the grammar school of his native town, by the Rev. Hugh Moises, and in May, 1766, instead of being apprenticed to the coal business, as his father had designed him to be, he was sent to his brother William, afterward Lord Stowell, who was then a tutor at Oxford. He was entered a commoner of University college, was chosen to a fellowship in July, 1767, took his bachelor's

degree in Feb. 1770, gained the chancellor's prize of £20 for an English prose essay in 1771, intending all the while to take orders, but this plan was changed in 1772 by his running away with Miss Elizabeth Surtees, the daughter of a Newcastle banker. He was married at Blackshiels, in Scotland, Nov. 19. The bride's family for a while refused to see her; but about the beginning of the next year the sum of £2,000 was settled upon each of the young couple by their respective parents, and the newly married pair went up to Oxford, where John was to study for the law. He was admitted of the Middle Temple in 1773, intending, however, to enter the church if a college living should fall vacant during the year of grace for which he was allowed to retain his fellowship after marriage. The anniversary of his marriage destroyed his last hope of ecclesiastical preferment, and he thenceforth bent his whole mind to the profession which circumstances seemed to have forced upon him. In 1774-'5 he was a tutor in University college, where, however, he probably did no more than superintend the law studies of some of the members, and at the same time he obtained the appointment of vice-principal of New Inn hall and vice law professor, his duties being to read the lectures written by his superior, Sir Robert Chambers. Beside the faithful study of Coke upon Littleton, he read and remembered all the reports, rising at 4 in the morning and reading until late at night. In 1775 he removed to London, where an eminent conveyancer, Mr. Duane, took him into his office without the customary fee; and in Feb. 1776, he was called to the bar. In after life he loved to speak of the difficulties of his early career; but in truth, after a shorter period of inaction than falls to the lot of most young lawyers, he seems to have risen steadily, and his fortune was made by his famous argument in the case of *Ackroyd vs. Smithson*, which Lord Thurlow decided in his favor on appeal in March, 1780. In the following year he still further advanced his prospects by his display of ability in the Clitheroe election case, which he undertook in the absence of other counsel, at a few hours' notice. A plan which he had entertained of settling in Newcastle was now abandoned. In June, 1783, on the formation of the coalition ministry of Fox and Lord North, he was one of several junior counsel who were called within the bar, and a few days after he was made a bencher of his inn of court. The influence of Lord Thurlow procured him a seat in the house of commons as representative of Lord Weymouth's borough of Weobly, and on Dec. 20, 1783, he delivered his maiden speech in opposition to Mr. Fox's East India bill, but with little success. Scott, in fact, was no orator, and though he afterward spoke with effect, especially on legal questions, and proved a powerful member of the tory party, he never acquired the fame of a good debater. On the accession of Mr. Pitt, in March, 1784, he came into parliament again as a member for Weobly, but in the following year he supported Mr. Fox in

the famous Westminster scrutiny case, and laid down the principle which has since passed into law, "that the election must be finally closed before the return of the writ, and that the writ must be returned on or before the day specified in it." His first official appointment was to the chancellorship of the county palatine and bishopric of Durham, in 1787; and in June, 1788, he was made solicitor-general, and received the honor of knighthood. Scarcely had he entered upon his new office, however, when the great political crisis arising out of the king's insanity threatened to turn him and his party adrift. Mr. Pitt proposed to confer limited powers as regent upon the prince of Wales by act of parliament, and this measure the solicitor warmly upheld, advocating the use of the great seal in the king's name, and broaching a doctrine which virtually placed supreme power in the hands of the person who held the seal for the time being. The bill was stopped in its passage by the king's recovery, but the line of action then laid down dictated the course of the ministry at a later period. In 1793 Sir John was made attorney-general, and as such conducted the famous state trials of 1794, in which he was opposed to Erskine. Scott failed to obtain a conviction, notwithstanding a speech of 9 hours' duration, and was, moreover, exposed to considerable bodily danger from the excited populace. In July, 1799, on the death of Sir James Eyre, he obtained the post of chief justice of the common pleas, and with it the rank of Baron Eldon of Eldon, his title being taken from an estate which he had purchased in the county of Durham. Shortly after the formation of Mr. Addington's ministry, in 1801, he became lord chancellor, receiving his appointment, it is said, directly from the king, who was pleased to intrust the great seal to one whose anti-Catholic zeal accorded so well with the royal sentiments. He contributed to the overthrow of Mr. Addington and the formation of Pitt's second administration, in which he retained his office, but he resigned it when the whigs came into power under Mr. Fox and Lord Grenville, in Feb. 1806. He was an active member of the opposition, and with the purpose of breaking down the whig cabinet by enlisting sympathy for the princess of Wales, he is supposed to have produced, in conjunction with Mr. Perceval, the famous "Book," whose origin was so long a mystery; but its publication was stopped when the tories came into power by the cry of "danger to the church," and on April 1, 1807, Lord Eldon took his seat again upon the woolsack. He was now at the height of favor and influence; his intimate relations with the king, no less than his official position, gave him a share in the administration such as no chancellor had enjoyed for many years; and though the assertion of Lord Brougham that he did three fourths of the governing of the country for a whole generation may be exaggerated, it is certain that at times when the king was notoriously incompetent he put the great seal to uses from which his more timid associates drew back, and in parliament the

severest strictures were passed upon his conduct. When the recovery of the king became no longer probable, Lord Eldon began to cultivate the favor of the regent, suddenly took side against the princess Caroline, and bought up as many as possible of the few copies of the "Book" which had got into circulation. In the ministerial intrigues following the assassination of Mr. Perceval he was the secret adviser of the prince, and the real author of Lord Liverpool's administration, which lasted with slight changes until the death of that minister in 1827, a period of 15 years. Lord Eldon's devotion to his "dear young master" was not without reward. On the death of George III. he was confirmed in his office, and by his subsequent part in the matter of the proposed divorce he earned the dignity of Viscount Encombe and earl of Eldon, which George IV. conferred upon him, July 7, 1821. But with the introduction of more liberal views than had hitherto ruled the nation, Lord Eldon's influence began to wane. Though still honored, he was less and less consulted. The ideas which he had brought with him from the previous generation, his uncompromising hostility to reform in law or parliament, his firm stand against Catholic emancipation, his coercion of the press, were no longer the principles of the government; and when Mr. Canning became minister, in 1827, he resigned the great seal, and was succeeded by Lord Lyndhurst. He never again took office, though he showed on several occasions a readiness to do so; and in 1835 he withdrew entirely from public life, taking with him a large fortune, the legitimate fruit of his position. As a lawyer, Lord Eldon ranks among the greatest who have ever adorned the bench or bar of England. Without a mind of the highest order, and little versed in the civil or in foreign codes, he was unsurpassed in knowledge of English law and in subtlety and acuteness of intellect; but his habitual hesitation in deciding, beside proving ruinous to suitors, encumbered the court of chancery with a vast arrear of causes which was often the subject of parliamentary animadversion. Hence, according to Mr. H. Twiss, his biographer, it was in the common law courts, where he was forced to decide without delay, rather than in the courts of equity, that he gained his greatest reputation. His opinions, from the study bestowed upon them, are of the first value, but they are often expressed in confused and obscure language. As a politician, he was distinguished by adroitness, tact, and a boldness strangely in contrast with his hesitation on the bench; but he was not a great statesman, and knew little of foreign politics. He had a horror of innovation, looked upon the reform bill of 1831 with mingled fright and amazement, and, with a morbid fondness for political prosecutions, boasted that he had caused more actions for libel in 2 years than had taken place in 20 years before. His demeanor on the bench was courteous and affable. His domestic life was eminently happy and virtuous; his good humor seldom forsook

him, and he had the reputation of being one of the most entertaining story tellers of his day. In his "Anecdote Book," a sort of autobiography compiled in his old age, he does little, however, to sustain his character as a humorist, and shows a lack of literary culture not surprising in one who from the age of 22 read nothing but law books and the newspapers.

ELEANOR OF AQUITAINE, queen of France and afterward of England, born in 1122, died March 31, 1204. She was the eldest daughter and heiress of William IX., duke of Guienne or Aquitaine, and was married, Aug. 2, 1137, to Prince Louis, who in the same year succeeded to the throne of France as Louis VII. She was gay, frivolous, a lover of poetry and art, and could not sympathize with the ascetic spirit of her husband. She accompanied him on the second crusade to the Holy Land in 1147. At that time he complained of her preference for other men, and on their return from Asia they were divorced, March 18, 1152. A short time afterward she bestowed her hand upon Henry Plantagenet, the future Henry II. of England. This alliance, which made Henry master of Eleanor's vast possessions in France, produced pernicious and protracted wars between France and England. She bore him many children, but his infidelities and neglect changed her love into hatred. She incited her sons Geoffrey and Richard to rebel against their father, was arrested in 1174, and remained in confinement until after Henry's death in 1189, when she was released by his successor, Richard I., Cœur de Lion, who placed her at the head of the government on his departure for the Holy Land. She negotiated his marriage with the daughter of the king of Navarre, and went to Germany with his ransom from captivity. She afterward retired to the abbey of Fontevrault, and surviving Richard, lived to see him succeeded by one of her other sons, John Lackland, the signer of Magna Charta. She was a favorite personage with the troubadour poets of the day, and appears in a very different light in their works from that in which she is represented by the French and Norman chroniclers.

ELEATIC SCHOOL, a group of Greek philosophers, beginning with Xenophanes of Colophon, who settled in Elea or Velia, a Greek colony of southern Italy, in the 6th century B. C., and whose principal disciples were Parmenides and Zeno, both of Elea, and Melissus of Samos. Some of the ancients also ranked Leucippus and Empedocles among them, which has led several historians of philosophy to distinguish two Eleatic schools, one of metaphysics and the other of physics. But apart from the radical difference which separates the doctrines of Empedocles and Leucippus from the system of Xenophanes and Parmenides, there is no evidence that the latter philosophers were at all associated with the former. It can only be affirmed that they were all contemporary, and that the writings of Parmenides probably contributed to the modification of Ionian ideas

wrought by Leucippus, and to the changes in the system of Pythagoras made by Empedocles. The general spirit of the school may be defined as an attempt, perhaps the first ever made, to refer all science to the absolute and pure ideas of the reason. There are, according to the Eleatics, two kinds of knowledge, that which comes to us through the senses, and that which we owe to the reason alone. The science which is composed of the former is only an illusion, for it contains nothing true, fixed, and durable. The only certain science is that which owes nothing to the senses, and all to the reason. Children and the untaught may believe in the reality of sensible appearances, but the philosopher who seeks the foundation of things should appeal only to the reason. There are two principles in nature, on the one side fire or light, and on the other night or thick and heavy matter. These principles are distinct but not separate; they act in concert, playing together a perpetual and universal part in the world. The world is bounded by a circle of light as by a girdle, and is divided into 8 parts, in the central one of which necessity reigns sovereign. The stars are but condensed fire, and the earth is the darkest and heaviest of all bodies. It is round, and placed by its own weight in the centre of the world. Men are born of the earth, warmed by the solar rays, and thought is a product of organization. From this commingling of fire and earth have begun all the things which our senses show us, and which will some time perish. But in all these physical phenomena there is no true science. Reason is the exclusive source of certainty, and reason conceives and recognizes as true nothing but absolute being, being in itself considered, that is, as disengaged from every particular, fleeting, and perishable circumstance, modification, or accident. Thus every thing which has ever begun to be, every thing which is susceptible of change or modification, of birth or destruction, has no veritable existence; it is not being, but only appearance. Beside being, in this sense of the word, there is, according to the Eleatics, only nothingness, and as this is but the negation of all things, one can neither affirm it nor deny it. Being is eternal, unchangeable, self-existent; it has neither past nor future, neither parts nor limits, neither division nor succession; it is then an absolute unity, and every thing else is but an illusion. Thus, the Eleatic system denies the data furnished by the senses, denies the generalizations and abstractions which the reason founds upon such data, and affirms only those necessary ideas which reason owes solely to itself, and which it employs in its operations. The result is a pantheism, in Xenophanes resembling the blended material and spiritual pantheism of Spinoza, and in Parmenides approaching the spiritual idealistic pantheism of Fichte.

ELEAZAR (Heb., God is help), the name of several ancient Hebrews. The most noted of them was the 3d son of Aaron, who held in his father's lifetime the oversight of the Levitical

order, and on Aaron's death was raised to the dignity of high priest. His pontificate was contemporary with the military government of Joshua, and the book of Joshua closes with an account of his death and burial.—**ELEAZAR**, son of Dodo, was one of David's 3 mighty men, who smote the Philistines till his hand was weary, and who with 2 others broke through the Philistine host to bring to David a draught of water from his native Bethlehem.

ELECAMPANE, the root of the plant *inula helenium*, a handsome shrub, which, introduced into America from Europe, is now common in our gardens, and grows wild in meadows and by the roadsides in the northern states. The root should be dug in autumn and of the second year's growth. It has an agreeable aromatic odor when dried, somewhat like that of camphor, and its taste when chewed is warm and bitter; water and alcohol extract its peculiar properties, the latter most readily. Its extracts afford the vegetable principles alantine or inuline, resembling starch, and helenine, which forms long white crystals. The powdered root or the decoction in water is used in medicine as a tonic and stimulant. It is prescribed in chronic diseases of the lungs.

ELECTOR, or **PRINCE ELECTOR** (*Kurfürst*), in the old German empire, the title of those princes who enjoyed the privilege of electing (*küren*) the emperor, or rather the king, for the rulers of the German empire were originally as such only kings. Under the Carolingians the government was hereditary. After their extinction the most powerful princes, such as the dukes of the Bavarians, Saxons, Swabians, Franconians, and Lotharingians, were accustomed to come to an understanding as to the one to be selected from among their number to rule over all the German tribes. This was done without any specific law, the electors being simply powerful enough to contest any election made against their will. But in the course of time the electoral privilege became a right inherent in certain territorial possessions, viz.: the archbishoprics of Mentz, Treves, and Cologne, and the principalities of the Palatinate, Saxony, Brandenburg, and Bohemia. The incumbents of these principalities acted as electors for the first time in 1256, when they chose Richard of Cornwall. A century later their exclusive privilege was guaranteed to them by the "Golden Bull." In 1648 an 8th electorate was established for the Palatinate, whose rights had been transferred to Bavaria during the 30 years' war; it became extinct in 1777. In 1692 the duchy of Brunswick-Lüneburg was raised to the rank of an electorate. When the German empire was tottering to its ruin in consequence of the wars with revolutionary France, the electoral college was entirely remodelled. The ecclesiastical electors having lost their possessions on the left bank of the Rhine, 3 secular princes were raised to the rank of electors, viz.: the margrave of Baden, the duke of Würtemberg, and the landgrave of Hesse-Cassel; beside these, the grand duke of

Tuscany, having been made archbishop of Salzburg and afterward of Würzburg, was recognized as an elector. But when, in 1806, the emperor Francis abdicated the German crown, the electoral system came to an end. Bavaria, Saxony, and Würtemberg became kingdoms (the electors of Brandenburg had been kings of Prussia since 1700); Baden was a grand duchy; and the elector of Hesse-Cassel was deprived of his dominions, which were afterward incorporated in the new kingdom of Westphalia. Thus, for 6 years, the title of elector had no legal existence, until it was revived after the downfall of the king of Westphalia by the elector of Hesse-Cassel, now the only prince bearing that title. The prince electors enjoyed not only the privilege of choosing the German kings, but also that of subjecting them to certain stipulations and conditions, which, in many cases, were so exacting as to leave the monarch scarcely a shadow of power. By the "Golden Bull" the electors are called "the seven columns and pillars of light of the holy empire," also "the members of the imperial body." It was one of their privileges to offer their advice to the emperor whether he asked for it or not. They were also entitled to all royal honors, except the title of majesty. The electors had each a special function in the administration of the empire or the imperial household. Thus, the elector of Mentz was arch-chancellor of the empire, chairman of the electoral college and of the diet; the elector of Treves was lieutenant arch-chancellor for Germany; that of Cologne the same for Italy; the elector of Bohemia arch-cupbearer; the elector of the Palatinate arch-dapifer and lieutenant of the emperor in the Rhenish provinces; the elector of Brandenburg arch-chamberlain; the elector of Saxony arch-marshal and vice-president of the diet; that of Brunswick-Lüneburg arch-treasurer. The electorates created shortly before the dissolution of the empire had not yet been endowed with special functions.—In the political system of the United States, electors are chosen by the people of each state to elect the president and vice-president. Each state chooses as many electors as it has members in the two houses of congress; and these electors meet at the capitals of their respective states, on the 1st day of January next after the election, and cast their votes for president and vice-president. These votes are then sealed up and carried by special messengers to Washington, where they are opened and counted in the presence of both houses of congress, and the result proclaimed by the president of the senate.

ELECTRA (in Gr., the bright or brilliant one), daughter of Agamemnon and Clytemnestra, sister of Orestes, Iphigenia, and Chrysothemis, was, when her father departed to the Trojan war, confided with her mother and brother to the care of Ægisthus. Clytemnestra yielded to the addresses of her guardian, and when after 10 years her husband returned to Greece he was murdered in his own house.

The vengeance of the guilty mother and her accomplice threatened death also to Orestes, but Electra discovered his danger, and sent him away to King Strophius of Phocis, who had him educated with his own son Pylades. Orestes had hardly attained the strength of manhood when Electra sent secret messengers to him urging him to undertake the duty of vengeance. With his friend Pylades he came in disguise to Argos, made himself known to his sister, and slew both Ægisthus and Clytemnestra in the palace. The guilt of matricide awoke the Furies against him, who stung him to madness, and pursued him over the earth. On the shore of the Tauric Chersonesus he was about to be sacrificed by the priestess of Diana, his own sister Iphigenia, who was ignorant of the relationship. According to some, the report even reached Greece that he had perished. Electra in despair rushed to the oracle of Delphi to learn the particulars. At the same time Orestes, Pylades, and Iphigenia arrived there. A casual word having at the last moment revealed Orestes to his sister, Electra was about to hurl a firebrand into the face of Iphigenia, when her arm was stayed by Orestes. Electra became the wife of Pylades, and the mother of Medon and Strophius. Her story has been treated from various points of view by almost all the great tragedians, by Æschylus, Sophocles, and Euripides among the ancients, and by Racine, Alfieri, and Goethe among the moderns.

ELECTRIC FISHES. The extraordinary modification of the peripheral extremities of nerves by which electricity is generated and discharged, is found in 4 genera of fishes, and in no other class of the vertebrata. The best known of these fishes will be described under TORPEDO; a second, the *gymnotus* or electrical eel, has been already mentioned under EEL; the other two will be briefly alluded to here, as there is no common name under which they would properly come. The 3d electrical fish belongs to the family of *siluridæ*, and the genus *malapterurus* (Lacép.). The *M. electricus* (Lacép.) differs from the common siluroids in having no anterior dorsal fin nor pectoral spine; the skin is naked and scaleless; there is an adipose dorsal fin near the caudal; the ventrals are just behind the middle, and the anal occupies about half the distance between them and the rounded caudal; the body is stout, the tail thick, and the head short and conical; the lips are fleshy, with 6 barbels; 5 villiform teeth in each jaw, none on the vomer. The fish attains a length of 18 or 20 inches, and is found in the Nile, Senegal, and other rivers of northern and central Africa; the color is cinereous or olive above, spotted and irregularly marked with black, whitish below; anterior nostrils tubular. The existence of a fish with benumbing powers in the Nile has been known for more than 300 years, but Geoffroy and Rudolphi were the first to give detailed descriptions of the electric organs. Valenciennes describes these as forming on each side of the body, between the skin and the muscles, 2 thin

layers of spongy cellular tissue uniting together small lozenge-shaped cells filled with gelatinous fluid, and 6 or more fine longitudinal membranes; combining the structure of these organs in the torpedo and gymnotus, and receiving the nervous influence both from the lateral branch of the vagus and from the ventral branches of the spinal nerves. The shock given by this fish is comparatively feeble, the discharge taking place when the head is touched; no shock is felt when the tail is grasped, as the electric organs do not extend to this part; in giving a shock the tail is moved, as if the muscles were active. This fish is much esteemed as food. The Arabs call it *raash* (thunder).—The 4th electrical fish belongs to the order *plecognathi*, family *diodontidæ*, and genus *tetraodon* (Cuv.). The upper and under jaws are divided by a median suture, so that they seem to have 2 teeth above and 2 below, incorporated with the jaws; in most of the species of the genus, the body, except the head and tail, is rendered rough by spines made erectile by the inflation of the skin, or naturally erect; but in the electric species (*T. electricus*, Paterson) the skin is destitute of spines, in conformity with the ascertained law that no electric fishes have either scales or spines; the body is brown above, yellow on the sides, sea-green below, and varied with red, green, and white spots. It attains a length of 7 or 8 inches, and is found in the lagoons of the Pacific. Its electric powers are comparatively feeble.—The most characteristic feature of all these batteries is their enormous supply of nervous matter; the electric organs generate the electricity, which is rendered active by nervous influence. In the torpedo the shock is best received when one hand is placed on the back and the other on the abdomen of the fish; in the gymnotus the intensity of the shock is in proportion to the length of the fish included between the hands; actual contact with the torpedo is not essential, as it is well known by the Neapolitan fishermen that the shock is felt when water is dashed upon it, the electric current passing up along the stream, the circuit being completed through the earth to the ventral surface of the fish; the dorsal surface is always positive, and the ventral negative. That this is the same as common electricity has been shown by Matteucci and Faraday; it renders the needle magnetic, and decomposes chemical compounds; by it heat is evolved, and the electric spark is obtained. The exciting nerves terminate in loops, as in the muscular tissue, and they arise like motor nerves from the anterior tract of the cord; the reception and conveyance of impressions, and the voluntary act which results in the shock, are of the same nature and follow the same course as in muscular contractions; a division of the electric nerves at their origin arrests all voluntary shocks, but an irritation of the ends of the nerves in connection with the organ is followed by an involuntary electric discharge, just as an irritation of the end of a divided motor nerve

in connection with muscle is followed by its contraction. The electric like the muscular power is exhausted by exercise, and recovered by rest; both are increased by energetic respiration and circulation, and both are exalted by the action of strychnine, which produces tetanic contraction of the muscles, and a rapid succession of involuntary electric discharges. The phenomena displayed by these fishes afford no ground for the opinion that nervous influence is identical with electricity; the former is no more identical with the latter than it is with muscular contractility; the contractility of the muscle resides in its fibre, and the electricity is generated in the battery of the fish; both are brought into play through nervous influence, but neither resides in or is a property of the nerves. The phenomena of heat, electricity, and phosphorescence within the animal body depend on chemical actions, which take place in the system just as they would in the chemist's laboratory, modified always by the mysterious vital principle. To show the energy of the electricity thus generated, it may be stated that, according to Faraday, the shock of the electric eel is equal to that of 15 Leyden jars of 8,500 square inches of surface; it is not surprising that a succession of these should prostrate a horse.

ELECTRIC LIGHT. This luminous appearance has been proved by Sir David Brewster to be of the same nature with all other light as regards the properties of polarization and single and double refraction, and he considers that the spark is a flame, consisting, like all other flames, of incandescent molecules in a state of minute subdivision, yet being producible in a vacuum it would seem not to be the effect of combustion. A most intense and steady electric light is evolved between two points of coke, forming the poles of a battery, and brought into close proximity. From its great brilliancy and cheapness this light would seem to be well adapted for illumination, especially for lighthouses, and if introduced into mines it would certainly prove the most powerful illuminating agent, without tending, like other lights, to contaminate the purity of the air. The difficulties which interfere with this application of the electric light are wholly of a mechanical nature, and though many expedients have been devised to remove them, the apparatus is still too cumbersome and costly for ordinary use. One of the principal obstacles to be overcome is the continual separation of the charcoal or coke points, as these are slowly consumed. A practical application was made in the year 1858 of the electric light, by Dr. Watson of the "Electric Power Light and Color Company," to facilitate the operations connected with the erection of the new bridge at Westminster. To give light to the workmen employed during low tide at night, he made use of an apparatus computed to have the illuminating power of 72 Argand burners, or of nearly 1,000 wax candles, placing it on the bank of the river about 200 feet distant from the working stage. Upon this 45 men were en-

gaged in pile driving. The battery, placed 2,000 feet off, was fitted with 72 cells. The reflector used was that known as Chappuis's. The light diffused over the stage was more brilliant than that of the brightest moonlight. It was fully as manageable as that of gas, and is said to be furnished at the lowest cost of gas (which in London is very low), a considerable profit being realized from the application of the residuary products of the battery to the manufacture of colors.—According to the recent experiments of M. Edmond Becquerel, made under favorable circumstances with a battery of zinc and platinum, the least cost of the electric light, compared with that of some other means of illumination, may be thus stated. Using as a standard the light of 350 sperm candles of best quality,

The cost of coal gas at \$1 60 per 1,000 cubic feet was...	\$0 85
“ oil (rape seed) at 17 cts. per lb. was.....	0 65
“ stearine candles at 82 cts. per lb. “	2 52
“ wax candles at 58 cts. per lb. “	3 12
“ electric light “	0 58

At the usual prices of gas in the United States, the electric light under present expenses of the battery is a more costly method of illumination, but may still be much cheaper than candles. (See ELECTRO-DYNAMICS.)

ELECTRIC TELEGRAPH. See TELEGRAPH.

ELECTRICITY. In the article AMBER, it has been already remarked that electrical phenomena were first noticed in this substance by the ancients, at least as far back as Thales of Miletus, who lived in the 7th and 6th centuries before the Christian era. From the Greek word for amber, *ηλεκτρον*, the name electricity was applied to the obscure force which produced these effects. As the substance gave its name to the phenomena, so the most obvious of these, the property of amber when rubbed of attracting light bodies, gave the name with the Arabs of *karabé*, or “catch-chaff,” to the fossil gum; and it is by no means certain, as suggested by Sir David Brewster, that the Greek name itself may not come from *ελκω*, to attract, and *θρίξ*, a hair or filament, or *θριον*, a leaf. This singular property of amber was regarded merely as a curious isolated fact; nor were the phenomenon of crackling sparks emitted in removing the clothing from the body, and the exhibition of animal electricity observed in the torpedo, considered as matters that could prove of any considerable interest or importance to mankind. Not until the investigations of Dr. Gilbert, of Colchester, England, made about the year 1600, had any progress been made toward elucidating or classifying these phenomena, or adding to their number. He found that a large number of substances were excited like amber by friction and attracted light bodies, that their capacity of doing this was greater in cool dry weather than when the air was warm and moist, and that many other substances were apparently deficient in this property. The publication of his experiments directed the attention of other philosophers to the subject, and this soon became one of the most interesting and popular fields of scientific research. New discoveries were

rapidly made, and with every new step gained the subject assumed a greater importance, extending in unexpected directions, so as to embrace phenomena of the highest interest to man, and linking itself with departments of physics with which it was before supposed to have no relation. Thus these investigations have continued for more than 200 years to attract the profound attention of the ablest philosophers; and at this day no subject is more worthy of their study, or opens a more promising field for original research, than the boundless range of electricity in its many departments. As developed in animal bodies, it has already been treated in this work in the article ANIMAL ELECTRICITY. (See also EEL (ELECTRIC), ELECTRIC FISHES, and TORPEDO.) In the present and succeeding articles it will be treated: 1st, in its ordinary exhibitions as produced by friction, heat, &c.; 2d, under ELECTRO-DYNAMICS, in the form commonly recognized by the name galvanic electricity; 3d, as connected with magnetism in the form called ELECTRO-MAGNETISM; 4th, in the application of this branch of the subject to the useful arts in ELECTRO-METALLURGY. Atmospheric electricity, with particular reference to the experiments of Franklin, will be more fully noticed under LIGHTNING. Electricity as developed by magnetism will be treated under MAGNETO-ELECTRICITY.—The prominent electrical phenomena are exhibited by very simple experiments. A glass tube, dry and clear, when rubbed with a warm silk handkerchief, attracts light objects, as slips of paper, gold leaf, a feather, or a pith ball suspended by a silken thread. The property thus developed is called electricity, and the body in which it is generated is called the electric. The light body attracted, after remaining in contact with the glass for a few seconds, and being then shaken off, is no longer attracted, but on the contrary is repelled. But if the light body be touched with the finger, it is then placed in a condition to be immediately attracted again by the glass. A stick of resin or sealing wax rubbed with dry flannel will be found to produce the same result as the glass tube; but if the two electrics be applied one on each side of the suspended pith ball or feather, and at a short distance from it, the light body is observed to be attracted toward one, and when repelled to be instantly attracted by the other; and thus it will continue to fly backward and forward between the two, until the excited condition of both bodies disappears. The electricity excited by glass is thus found to be of a different quality from that excited by resin. M. Du Fay, who made this discovery in 1733, distinguished these by the names of vitreous and resinous electricity, which names still continue in use. Dr. Franklin gave the name of positive electricity to that called vitreous, and negative to the resinous. These are now sometimes represented by the symbols +, plus, and —, minus. (The theories of Du Fay and Dr. Franklin are more fully discussed in the article ELECTRO-MAGNETISM.) If the silk used to rub the glass be pre-

sented to the pith ball, it will be found to act like the resin; and the flannel used to rub this will be found in the same way to possess the same kind of electricity as the glass. Hence, in the development of electricity by friction, one kind is found to be produced in the electric, and the other in the material used as a rubber, and the same quantity of electricity in each. In the multitude of bodies which may become electrically excited by being rubbed together, it is not always obvious which will possess the vitreous and which the resinous electricity. The numerous experiments that have been tried, however, seem to have developed some laws which determine this result. Of two bodies thus excited, that which radiates heat most readily assumes the positive electricity, and the other the negative. Silver rubbed upon lead is positively electrified, but if upon iron, which radiates heat better than silver, it takes negative electricity, and iron the positive. But this may be reversed in bodies of nearly the same radiating power, in case the one radiating best is heated, and its surface is quite rough. Surfaces which are uneven, so that the particles are considerably disturbed in the rubbing, incline to take the negative electricity; thus, when a rough and a smooth ribbon are rubbed across each other, the former is negatively and the latter positively electrified. A black ribbon rubbed upon a white one becomes negative, the surface probably being more rough.—In the experiment of touching the pith ball with the finger, its electrical property is found to be instantly removed, so that it becomes indifferent in its attraction either to the glass or the resin; touched with a metallic rod held in the hand, the same effect is produced. But the glass or resinous rods do not thus strip it of its electricity. A difference in bodies is thus noticed as to their property of conducting electricity, and a distinction is established between those which are good and those which are bad conductors. It is this facility of rapidly conducting away electricity that prevents many solid bodies from being regarded as electrics, though all of them may be made to develop electricity by friction. A metallic rod or tube provided with a handle of glass or resin may be made like the glass tube to develop electricity, its escape being checked by the non-conducting glass, which is said to insulate the metal. Bodies which thus act as poor conductors are called insulators, but the distinction between them is only in degree. Shellac, amber, resin, glass, brimstone, &c., may be called either good insulators or poor conductors. The same bodies also differ in their conducting property by slight changes in their composition, and by change in their structure, such as is caused by change of temperature; thus glass is made a conductor by being heated to redness, and vegetable bodies are changed to non-conductors by being deprived of their moisture. The metals are the most perfect conductors, and then follow charcoal, graphite, saline and animal fluids, ores, water, snow, animal bodies, &c. The worst conductor, which con-

sequently heads the list of electrics or insulators, is shellac, or perhaps gutta percha, after which follow amber, the resins, sulphur, wax, jet, glass, mica, gems and various minerals, silk, wool, hair, feathers, paper, baked wood, &c. But a coating of moisture upon these renders them conductors, as a coating of wax or resinous varnish upon the surface of the bodies classed as conductors deprives them of their characteristic property. An example of the immense differences which are found in the capacity of the various conductors to convey electricity is represented in the comparison of iron wire with water, the resistance to be overcome in passing through an inch of the fluid being found equal to that experienced in traversing 400,000,000 times the distance of the wire. The velocity of electricity along good conductors has been variously estimated by different experimenters, some making it to exceed that of light in its passage through the atmosphere. The principle of the movement is as obscure in the one case as in the other, as is our knowledge of the nature of the forces themselves. In a row of pith balls suspended near each other the excess of electricity contained in one is transmitted to the next by perceptible movement of the particles. As the distance which separates the particles is diminished, the capacity of rapidly conveying electricity is increased; but when the particles are brought into contact, no movement of this kind is apparent to the senses. So it is perhaps that the mind fails to conceive the mode by which the particles of air transmit the shock between the electric cloud and the earth, or those of a metallic wire through a long line of it, at the rate, it may be, of more than 100,000 miles in a second of time.—Various machines are in use for generating and collecting electricity by friction. A common form of these is a hollow cylinder of glass made to revolve upon a horizontal axis against a cushion or rubber stuffed with hair or wool and covered with soft leather. A flap of oiled silk, attached by one edge to the rubber, passes from this over the upper surface of the cylinder, upon which it rests, the object of which is to prevent the dissipation of the vitreous electricity as this is carried over from the rubber by the revolution of the cylinder. The supply is furnished by means of a chain attached to the rubber and leading to the floor or to the table. The rubber is thus not insulated, and the resinous electricity excited in it is not ordinarily collected for experiments, as is the vitreous. This is effected by means of a smooth metallic cylinder placed upon a solid glass leg, and extending parallel with the glass cylinder and about 2 inches from it on the side opposite to the rubber. Its ends are hemispherical, that no electricity may be lost by escaping from sharp edges. It is hollow, as weight and solidity are of no service, electricity at rest occupying only the surfaces of bodies. This portion of the apparatus is called the prime conductor. The electricity discharged from beneath the oiled silk is received upon metallic points, a row of which

project like the teeth of a rake from the side of the conductor, and point toward the glass cylinder an inch or thereabout below the silk flap. The development of electricity is greatly increased by the application of an amalgam paste to the surface of the rubber, and also, as Dr. Faraday recommends, by impregnating with it the silk flap. It is made of 1 part of tin and 2 of mercury, mixed with tallow or lard to form a soft paste. A better preparation is to melt 2 oz. of zinc and 1 of tin in a crucible, and then pour in 6 oz. of mercury. It is to be well shaken in a box until cold, ground to powder in a mortar, and then mixed with lard. The paste should be thinly spread and occasionally renewed. The glass cylinder and all the apparatus must be kept clean and free from dust, and its efficiency will be increased by some method of keeping it warm and dry, as by making the pedestals which support the rubber and prime conductor hollow and open at the bottom, the stand being made double so as to admit a small alcohol lamp under each pillar. By such a contrivance the machine may be made to operate satisfactorily in a state of the atmosphere which under ordinary circumstances is unfavorable for the exhibition of electrical phenomena. As the electricity is excited by turning the cylinder, its presence is immediately indicated in the prime conductor by the divergence of a pair of pith balls suspended by a conducting thread, as one of linen, from a curved wire fastened to the top of this conductor. Excited by the same kind of electricity, they repel each other. By presenting the knuckle to a brass ball, which is commonly attached by a stem to the conductor, a spark is drawn from it which is both seen and felt. When highly charged, a succession of sparks may be taken off with great rapidity to any either neutral or negatively excited body brought near to the knob; or if there be points or sharp edges upon the conductor, the electricity will be seen escaping into the air in brushes of faint light. The electric spark is accompanied by a sort of explosive sound, with a display of considerable force, sufficient when produced in water contained in a strong glass tube to burst this with violence. In this and its zigzag dartings it exhibits its resemblance to lightning, which is in fact the same phenomenon upon a large scale. It is accompanied with heat, and appears sometimes in one or another of various shades of violet, blue, green, red, and yellow, and is sometimes a bright white. From the discoveries of Dr. Fosinieri of the transmission of infinitely small metallic particles, when a spark is produced between 2 metallic bodies, and of a concave indentation made in each of them, he concludes that the heat and light of the spark proceed from the ignition and combustion of the particles of ponderable matter, and that these are projected in opposite directions. For the glass cylinder a circular disk of plate glass, $\frac{1}{4}$ or $\frac{3}{4}$ of an inch thick and 2 to 3 feet or more in diameter, is often substituted, and the most efficient ma-

chines are now generally constructed in this manner. The disk is set upon a revolving axis in a frame, the cross piece of wood over the upper edge of the disk supporting a double rubber, between the two parts of which the edge of the disk revolves, and another pair of similar rubbers are secured upon the base or platform, and by a screw are made to press between them the lower edge of the disk. A flap of silk passes from each rubber in the direction of the revolution of the disk, covering each side of it, and extending nearly one quarter of its circumference, where it meets the collecting points of the prime conductor. This is secured to a strong glass support, which projects horizontally from the frame on the side opposite the winch or handle, and then bends around like two elbows so as to present an extremity to the surface of the disk on two opposite edges. The arrangement is variously modified in different machines. An enormous machine, with a plate 11 feet in diameter, was in the Panopticon in Leicester square, London. The quantity of electricity developed increasing with the size of the plate, the power of this machine is probably greater than that of any other ever constructed. Dr. Hare of Philadelphia contrived a very neat form in which the disk was made to revolve horizontally. Other substances have been used instead of glass for the disks, as pasteboard soaked in copal or amber varnish, and coated with the same; wood has also been made into disks, and gum lac has been applied in the same way. A machine of great power was made in Brussels of a web of varnished silk, 25 feet long and 5 feet wide, revolving upon two wooden cylinders covered with woollen serge. As the cylinders were made to revolve by the exertions of 4 men, the silk passed between 2 cushions, each 7 feet long and 2 inches in diameter. These were covered with the skins of cats or hares, and could be made to press more or less upon the silk. The sparks produced by this machine were 15 inches long, and no one was inclined to receive one of them except upon the shoulder or elbow.—Phenomena have been frequently witnessed within the past few years in New York and other places in the northern portion of the United States, a notice of some of which by Prof. Loomis may be found in the "American Journal of Science" (vol. xxvi., July, 1858). Persons, especially children, wearing dry slippers with thin soles, and a silk or woollen dress, in a warm room heated to at least 70°, and covered with a thick velvet carpet, often become so electrically excited by skipping a few times across the room with a shuffling motion, and rubbing the shoe upon the carpet, that sparks are produced on their coming in contact with other bodies; and on their presenting a finger to a gas burner yet warm, the gas may be ignited. Sulphuric ether has been thus inflamed, and in dry cold weather sparks half an inch in length have been given forth by young ladies who had been dancing, and pulverized resin has been thus inflamed. Electricity is

also generated by the steam escaping from boilers impinging upon hard substances, as in passing through bent iron tubes, which terminate in jets or small orifices of box wood. These receive one kind of electricity (most commonly the negative), and the boiler, if insulated, is found to be charged with the other. This effect, according to the investigations of Dr. Faraday, is induced by the friction of the particles of water in the steam upon the discharging tubes. A machine was constructed for the polytechnic institution in London, with a boiler $6\frac{1}{2}$ feet long and $3\frac{1}{2}$ feet diameter, of the Cornish form, with the fire chamber in the boiler, from which sparks are obtained 22 inches long, and so large and rapid in their succession as to appear like a continuous flame. One of these so-called hydro-electric machines has been constructed at the faculty of science in Paris. It is provided with 80 jets for the escape of the steam. The sparks form brilliant jets of fire by their rapid succession. Each spark is about a foot in length, and several inches in breadth. Electricity is moreover developed during the changes which bodies undergo in mechanical structure, and in others produced by chemical action; as, for example, when sulphur, wax, and other bodies, after being melted, return to a solid state on cooling, when gases are disengaged, and vapors are evolved; from the leaves of living plants as they disengage oxygen and carbonic acid; and also from decomposing vegetable matters. As rapid motion and friction develop it, the falling of rain and hail and the blowing of the wind may produce it in the enormous quantities in which it is generated in the atmosphere, and by evaporation still more may be developed by these atmospheric influences. As an example of the amount sometimes produced in the atmosphere, it is stated in Livingstone's "Travels in South Africa" (p. 137) that the hot wind which blows during the dry seasons over the desert from north to south "is in such an electric state that a bunch of ostrich feathers, held a few seconds against it, becomes as strongly charged as if attached to a powerful electrical machine, and clasps the advancing hand with a sharp crackling sound." By a little friction the fur of the mantles worn by the natives gives out a luminous appearance. It is produced even by the motion communicated in riding; and a rubbing with the hand causes sparks and distinct crepitations to be emitted. Dr. Hooker observed similar phenomena during a snow storm on Ben Nevis in 1825, the electricity causing a hissing sound in the air, and affecting the hair of the members of his party. De Saussure and others witnessed the same effects on Mount Breven in 1767.—What was supposed to be a peculiar quality of electricity was first observed by Dr. Seebeck of Berlin, and named by Prof. Oersted the thermo-electrical current. It is produced when two pieces of metal joined together at both ends are heated or cooled at one of their junctions. The current manifests its presence by causing the magnetic needle to deviate from its position. The direction of the current

is found to be different, according as the action is that of cooling or of heating. The effect is supposed to be owing to the molecular change which the metal experiences by change of temperature. Other electrical phenomena have subsequently been exhibited by this method of excitation, and the production of sparks visible in the daylight, the decomposition of water, &c., cause this form of electricity to be now regarded as not differing from that generated by more familiar methods. The electric spark was obtained by Prof. Henry and Prof. Wheatstone in 1837 with a small cylindrical bundle of 33 elements of bismuth and antimony, $\frac{1}{4}$ of an inch in diameter, and $\frac{1}{2}$ of an inch long.—Electricity is thus obtained by various methods, and insulated bodies may be charged with it by being brought in contact with the conductor, either directly or through a chain, wire, or other conducting body. Indeed its influence is felt upon bodies around that are not in contact with the electrified conductor, as is shown by bringing near to this an insulated metallic body, as a cylinder, upon which several pairs of pith balls are suspended by linen threads. An electrical excitement is seen by the divergence of these balls to be immediately induced; and it will be found that those suspended across the end nearest the prime conductor are affected with the opposite electricity from that of the conductor, and those at the remote end by the same electricity. The electricity that was quiescent in the body thus appears to have been disturbed by its proximity to another highly charged, and that portion which was of an opposite nature to the disturbing agent is drawn toward it, while that of the same nature is repelled. Between the two extremities is a point where no electrical excitement is displayed. This phenomenon is called electrical induction. It is upon this principle that the apparatus for collecting and retaining large quantities of electricity is based. The most simple form of it is a pane of glass coated on both sides with tin foil, with the exception of a margin of an inch in width all around. One side of this being placed upon some conducting body communicating with the floor, and the other side being connected with the charged conductor, the latter side is itself charged with the electricity of the conductor, while the metallic coating on the other side becomes at the same time charged with the opposite electricity. By this method charges of electricity may be accumulated proportional to the amount of metallic surfaces. The panes may be multiplied in number, and made to act as one by connecting all the insulated or upper coatings by a good conductor with that communicating with the prime conductor, and all the other surfaces by another good conductor with that communicating with the ground. The tendency of the two electricities thus accumulated is to rush together, and this they do instantaneously when a conducting medium is presented to each. The common method of restoring their equilibrium is by means of a stout wire or rod, with a metallic knob at each end, the wire bent or

turned by a hinge to the proper curvature, and passing through a glass handle, by which it is held. This is called a discharging rod. A chain will effect the same purpose, or the discharge may be taken through the body by presenting one hand to each surface of the glass; and if any number of persons join hands, and the two at the extremities present a hand one to the upper and the other to the lower surface of the glass, the shock will instantly pass through them all. Instead of panes of glass, it is found more convenient to use wide-mouthed glass bottles or jars, which are coated inside and out nearly to the top with tin foil. These are called Leyden jars, from having been first used by Musschenbroek and others at Leyden in 1745. A cover of baked wood is fitted upon each one, and through the centre of this a brass rod passes nearly to the bottom, with which it connects by a short chain; its upper end terminates in a brass knob 2 or 3 inches above the cover. A number of these arranged together, the brass knobs at the top being connected by wires or a chain, and the outer coatings being also brought into communication with each other by good conductors, constitute an electrical battery, and this is charged from the prime conductor by connecting one of the knobs with it. With a battery of this kind, the metallic coatings of which amounted to 225 square feet, and charged by a powerful electrical machine constructed by Van Marum at Haarlem, Holland, shocks of such power were obtained that a piece of boxwood 4 inches long and 4 in diameter was rent apart, and the report produced was so loud as to stun the ear, while the flash dazzled the eye with its brilliancy. The heat generated was so intense that a small iron wire about $\frac{1}{16}$ of an inch thick and 25 feet long was fused into red-hot globules, which scattered in every direction. A piece of tin wire $\frac{1}{8}$ of an inch thick and 8 inches long disappeared in blue smoke, globules of melted tin at the same time falling upon a piece of paper and repeatedly rebounding. Magnetism was also developed by the shock, so that polarity was given to steel bars of 9 inches in length, nearly $\frac{1}{4}$ an inch wide, and $\frac{1}{8}$ of an inch thick. The machine which produced these effects was constructed of two disks of glass, 5 feet 5 inches in diameter, set upon the same axis, and provided with 8 rubbers, each of which was about 15 inches long and 2 inches wide. Bodies 40 feet distant were sensibly affected by the electricity excited by this machine, and pointed wires 28 feet distant directed toward the conductor were tipped with a star of light; and when a metallic ball communicating with the ground was presented to it, a brilliant jet of light 2 feet or more in length darted forth with a zigzag motion, throwing luminous brushes of light into the air.—It is interesting to observe the close relation between the pane of glass partially covered with metallic coatings and the arrangement of the natural bodies—the perfectly conducting atmosphere, corresponding to the glass, overlaid with the stratum of clouds of vapor and touching by

its under surface the solid earth. Whenever either the stratum of clouds above or the earth below becomes charged with one kind of electricity, the opposite kind is induced in the other, and the same tendency is manifested of these two electricities to rush together and neutralize each other, as is observed in the electrified coatings upon the glass; and if with our imperfect apparatus, covering a few square feet of surface, we can produce effects so startling, we may the better appreciate the terrific power gathered upon surfaces adapted for accumulating electricity, extending over areas of many square miles, and charged by the action of the most powerful agents in nature. A particular quality of this natural electricity, common to it and the machine electricity generated by friction, is its intensity, or its property of violent action. In this it differs from the electricity generated by the galvanic battery, which is distinguished for the mildness of its character, while the quantity is remarkably large. The natural electricity obtained by friction has been compared to the heat developed in a bar of red-hot iron, while that produced by chemical action is more analogous to a larger quantity of caloric diffused through a vast body of water. The common electricity also, after being accumulated, has the property of remaining for a considerable time in an excited condition, and for this reason has been called statical or reposing electricity, in contradistinction to that generated by the battery, which exists only while it is evolved, and for this reason is termed current electricity. In most of the instances in which electricity is applied to useful purposes the violent shock is not what is required, but the feeble and continuous action of the galvanic current. It is consequently in the description of this form of electricity that the practical uses of this agent will be treated. One use of the machine, however, may be noticed in this place. When a shock is passed through strips of gold leaf placed between slips of window glass, the gold is melted and driven into the pores of the glass. On this principle metallic colors are impressed in ornamental figures upon silk or paper. The design is first cut out as in stencil plates on a piece of thick drawing paper, and this being laid between a piece of gold leaf and the object to be impressed, and the whole placed under a weight and the shock passed through the gold leaf, portions of this are projected through the lines of the design, and fixed upon the ground intended to receive them. By the shock various chemical compounds may be decomposed and gaseous mixtures separated, and their elements made to assume new combinations; but these phenomena are better exhibited by the battery, and will therefore be described in another article.—Statical electricity is developed in some cases by other agencies as well as by friction, as by pressure and heat. The mineral Iceland spar is especially remarkable for the electrical excitement occasioned in it when a rhomb held in one hand by its two

opposite edges is touched upon two of its parallel faces by the fingers of the other hand. Being then held near the small needle of the electroscope (an instrument to be hereafter noticed), the mineral is shown to be excited by vitreous electricity. A number of other crystals, as fluor spar, topaz, mica, aragonite, &c., all of which are capable of being cleaved into laminæ, manifest the same property. The electricity thus developed has been found to continue, as noticed by Haüy, for 11 days without dispersion. When two substances are pressed together, the electricity is developed only on their separation, and in one it is vitreous and in the other resinous. Electricity obtained by heat is exhibited also by a variety of minerals, and especially by the crystal of tourmaline. Whenever its temperature changes, electricity is excited in it, in one end of the positive and in the other of the negative kind. If the change of temperature is rapidly produced, the electricity is sufficiently intense to attract light bodies to the surface of the crystal. When the crystal is allowed to cool after being heated, the electricity developed at each extremity is the opposite of that manifested during the heating.—In conducting experiments in electricity, a variety of instruments have been introduced in connection with the machine, some of which, as electrometer, electrophorus, electroscope, &c., may properly be noticed in their alphabetical place in this work, though for their full description the reader must look to some of the many able special treatises upon this subject, among which that by Sir David Brewster holds an important rank, and has furnished most of the materials for the many compilations. The *Traité de l'électricité théorique et appliquée* (Paris, 1854-'58) of M. A. De la Rive presents the science most completely in its latest developments, and in its several departments. An English translation of it, by O. V. Walker, F. R. S., entitled "A Treatise on Electricity in Theory and Practice," has been published (3 vols. 8vo., London, 1853-'58). See also Faraday's "Experimental Researches on Electricity" (3 vols. 8vo., London, 1844-'55).

ELECTRO-DYNAMICS (Gr. *ηλεκτρον*, amber, and *δυναμις*, power). The kind of electricity developed by friction may be kept quiescent, as accumulated in the Leyden jar, and at any time be made to manifest instantly its intensity of action, as when a fulminating powder is exploded. But, as developed by chemical action, electricity in the form of a constant current manifests other properties; and its effects are exhibited only during the flow of this current, disappearing instantly on its cessation, as the light of the sun is lost when its rays are intercepted. Electro-dynamics is the name applied to this branch of the science, in contradistinction to electrostatics, the term used to designate the other. The distinction is not, however, a satisfactory one; and when the nature of this subtle agent is more perfectly comprehended, it will no doubt give place to a more exact exposition. But at

present the former is the comprehensive term which includes whatever belongs to the electrical current generated by the voltaic pile or battery, the thermo-electric circle or the electromagnet. Under the heads **THERMO-ELECTRICITY**, **ELECTRO-MAGNETISM**, and **MAGNETO-ELECTRICITY**, the last two will be respectively treated.—The discovery of this form of electricity has been referred to in the article **ANIMAL ELECTRICITY**. It is manifested in the chemical action of substances upon each other; not often exhibited, it is true, unless sought for, but still manifested, even when it is so feeble that the electrical excitement produced is its only indication; witness the slight shock to the animal tissue, causing sudden contraction, when 2 different metals placed one below and the other above the tongue, or against the inner surface of the lip, are brought in contact at their edges. The saliva in this case acts chemically upon each metal, producing in the one most affected resinous or negative electricity, and in the other vitreous.* The former is analogous to the rubber in the electrical machine, and is called the generating plate; the other, answering to the prime conductor, is called the conducting plate. The greatest effect is produced when (both being good conductors) the one is rapidly acted upon by the fluid which wets them, and the other is of a nature to be less affected. Two such plates are called a galvanic pair; the term element is applied sometimes to the pair, or more generally to one of the plates. They are commonly one of zinc and one of copper, silver, or platinum, and they are immersed in water mixed with sulphuric acid. They are allowed to touch each other only above the surface of the fluid, or instead of directly touching, a wire of any length may proceed from each as a conducting medium, through which the electrical current is transmitted, and its effects are developed with the same energy at their extremities, or the poles of the pairs when brought into contact, as if the upper edges of the 2 plates were themselves brought together. By the contact being effected an extraordinary capacity is produced in the solution of acting upon the zinc plate, while the other appears to be proportionally protected. The water is decomposed, its oxygen unites with the zinc, the resulting oxide of which is dissolved by the sulphuric acid as a sulphate, and the hydrogen appears in minute bubbles on the surface of the other plate. These bubbles continually increase in size and escape to the surface. The electricity is supposed to be generated at the zinc plate or that most acted on by the acid, and to pass through the fluid from this to the copper or metal less affected by the acid, and thence through whatever conductor is interposed between the upper portion of this and that of the zinc plate. The zinc plate, supposed

* A curious instance of this phenomenon is presented by placing a leech upon a silver dollar, and this upon a sheet of moistened zinc. The animal on attempting to crawl off evidently receives a startling shock on touching the zinc, which induces him to draw suddenly back, and thus he is kept a prisoner upon the silver.

to be the source of the electricity, is called positive, and the copper plate, which receives the current, negative. Some suppose two currents are excited, which pass in opposite directions, and others believe that the excitement is not of the nature of a current at all. If the circuit is complete, no evidence of this action is apparent except the rapid oxidation and disappearance of the zinc, and the production of the hydrogen; but if this be interrupted by the smallest break or by the interposition of a very fine wire, the passing of the current is manifested, not, as with the machine electricity, by the quality of tension which enables it to leap across the non-conducting air, with an explosive spark, or to pierce an interposed card or other poor conductor, but intense heat is developed at the points where the current is partially obstructed. If, however, the number of pairs be greatly multiplied, the electricity then approaches the character of that generated by the friction machines. When a fine wire of a poor conducting metal is used to form a part of the circuit, this is immediately oxidized and disappears in vapor. If the break is closed by bringing the terminating points in contact, brilliant sparks are produced; and if points of coke or dense charcoal, such as that made from boxwood, are used for the poles or electrodes of the circuit, a continuous light of intense brilliancy is emitted, even if the poles terminate in a vacuum, and to some extent also if under water, thus evidencing that it is not the effect of combustion. In the passage of the current through most compound fluids in which the plates are immersed, the fluid is decomposed, one of its elements, as the hydrogen, appearing at the negative, and the other, as the oxygen, at the positive side; and the same decomposition is effected if, instead of immersing the plates in the compound fluid, the conducting wires anywhere on the circuit are each made to terminate in it, but not in contact with each other. In this case, however, it is the wire attached to the copper which is acted upon; and that attached to the zinc (now the negative pole because it receives the current), which gives off the hydrogen. This is the arrangement used for effecting decomposition, and the interposed vessel in which the compound is placed is called the decomposition cell. It is in reference to the phenomena which take place in this, that bodies are distinguished as either electro-negative or electro-positive; or, according to the nomenclature of Prof. Faraday, as anions or cations. The former in the decomposition tend to the anode or positive pole of the battery, that proceeding from the copper plate, and the latter to the cathode or negative pole of the battery. (See CATHODE.) Hydrogen, the alkalies, and the metals, appearing at the negative pole of the battery, are cations; oxygen, chlorine, iodine, fluorine, and the acids generally, tend to the other pole, and are called anions. But this classification of bodies must not be confounded with their division into positive and negative with reference to their action when applied in the battery to excite the electric current. Zinc

in this arrangement has been called the electro-positive metal, and copper the electro-negative, terms which have merely a relative signification; for if potassium were substituted for the copper, or platinum for the zinc, the electrical properties of the metals would be found reversed. The following table presents the metals named in the order in which they stand to each other when used for electric plates, with the acid mixtures usually employed, as water with sulphuric or hydrochloric acid. The most positive is the first named, the most negative the last. Each one is positive to those which succeed, and negative to those which precede it. Those furthest separated would consequently produce the highest electric excitement:

1. Potassium.	6. Lead.	10. Silver.
2. Zinc.	7. Copper.	11. Antimony.
3. Cadmium.	8. Bismuth.	12. Gold.
4. Tin.	9. Nickel.	13. Platinum.
5. Iron.		

This arrangement, however, is not constant with all fluids, nor always with the same fluid at different degrees of concentration, or at different temperatures. A number of pairs being arranged in succession, and the zinc plate of one being connected by a good conductor to the copper of the next, and so on, the whole may be made to act as one pair with increased effect. Enlarging the size of the plates also increases the power. Volta's arrangement was a pile of disks of copper and zinc, one of the latter being placed at the bottom, upon it a cloth moistened with some acid liquor, separating it from the copper above, on which rested another zinc disk, then the wet cloth, copper, zinc, and so on, the uppermost disk being one of copper. Two wires, one from each extremity of the series, meeting together, complete the circuit, and electrical action is excited throughout the whole series. On the supposition of there being two currents, the electricity developed by the chemical action of the acid upon the lowest zinc plate renders this positively excited, and the proximate copper negatively so. This, in actual contact with another zinc plate, tends to impart to it directly its own kind of electricity, but this zinc disk also, being itself positively excited, transmits the negative electricity to the next copper with an additional charge of its own creating; and thus the negative current goes on accumulating toward the uppermost copper disk, while the positive electricity accumulates in the same manner in the other direction at the lowest zinc. The conducting wires, like those of the electrical machine, by coming in contact restore the disturbed equilibrium, one electricity neutralizing the other. This original arrangement is called the voltaic pile. It was modified, however, by Volta himself, by the substitution of a liquid for the moistened cloth; and the plates being immersed in this on the same principle of their arrangement in the pile, the apparatus is called the voltaic or galvanic battery, the latter name having reference to Galvani, who discovered this kind of electricity, though he knew nothing of this mode of developing it.—It has been al-

ready stated that by increasing the number or size of the plates the electrical effects are augmented. It is not a matter of indifference, however, which of these modes is adopted. It is found that increasing the area of a single pair of plates adds to the capacity of generating heat even in a greater ratio than the increase in the surface of the plates, and at the same time magneto-electricity is more thoroughly developed; but the intensity of the electrical force is not sensibly affected, nor its power of producing chemical changes in bodies introduced into the circuit, which is a property belonging to that condition expressed by the term intensity, and not to the other, dependent, it is supposed, on quantity. But if the size of each pair of plates continue the same, and their number be increased, the electricity developed is more of the nature of that generated by the electrical machine, which is distinguished by its character of intensity, as is manifested in its power of giving shocks, and of passing to some extent through imperfect conductors. It is this form of battery which is employed to effect chemical decompositions. That used by Sir Humphry Davy in the experiments which resulted in his discoveries of the metallic bases of the alkalis and earths, consisted of 2,000 pairs of plates, with areas exposed to the action of the acids amounting to 128,000 square inches. Various modes are adopted for arranging these plates, but the principle is the same in all. The copper and zinc plates of each pair are to be brought in contact directly or through the medium of a slip of metal, while the communication between the zinc and copper of adjoining pairs is through the acid liquor in which they are immersed. The arrangement may consist, as in the trough battery, of a number of cells formed by partitions, which neither the acid nor the electric current can traverse, a copper plate being opposed to a zinc plate in each cell, and the communication being from the zinc to the copper through the fluid. The copper is connected by a slip of metal passing over the partition with a zinc plate in the next cell, opposed to which is another copper plate, and so on. The last copper communicates with the first zinc by a wire outside of the whole, thus completing the circuit. Or, instead of a trough divided into cells, a number of glass tumblers may be arranged in succession, each holding a zinc and a copper plate, which are connected by strips of metal with their opposite plates in adjoining tumblers. This was the arrangement adopted by Volta. In Cruikshank's form of the battery, the zinc and copper plates are applied one upon the other and soldered together, and thus inserted as partitions in the trough, the zinc plates all facing one way and the copper the other. The cells thus made being then partially filled with dilute acid, the arrangement is seen to be the same as that of the voltaic pile. Batteries constructed with a few plates of great size develop a vast amount of electricity, but in a current of feeble intensity. Their action can consequently

be extended only to short distances, and then through the best conductors; but if the current be interrupted by the interposition of fine wire of poor conducting material, as iron, steel, or platinum, an extraordinary degree of heat is developed. A remarkable battery of this description was first made by Dr. Hare of Philadelphia, with which he fused a number of substances before regarded as infusible, including charcoal; platinum he described as running like water under its action. For convenience of room the plates were arranged in coils, the zinc and copper being separated by a space of only $\frac{1}{4}$ of an inch. From its power of producing heat he called this form of battery a calorimotor. Similar batteries have since been made with an exposed area of 400 square feet. By connecting a number of distinct sheets of the same metal together by a good conductor, the effect is produced of one large sheet. Heat is also developed by increasing the strength of the acid, at least up to a certain point. The chemical action then goes on with greater rapidity, and a proportionate quantity of electricity is set free. The deficiency of this kind of electricity in intensity renders it necessary, when the effect is to be transmitted a considerable distance, as for firing charges under water, or igniting several charges at once in blasting rocks, to add a second battery or to increase the number of the pairs of plates. The best conducting material should be used, and this in a wire of large size. The metals vary greatly in their capacity of conducting the electric current. Their proportional value in this respect is represented in the numbers respectively accompanying those named below :

Silver, copper, each..	120	Iron, platinum, each..	24
Gold	80	Tin.....	30
Zinc	40	Lead.....	12

The place for brass is between copper and gold. In the article **BLASTING** is a description of a cheap battery used in Scotland, by which discharges have been produced at a distance of 500 feet. A second battery added would carry the effect still further. Cast iron is substituted in this for the copper plate, being found more efficacious for generating electricity in quantity than either copper or silver. The effect of the intense heat is beautifully exhibited by a number of interesting experiments, which should be performed in a dark room. When one wire of the battery is made to terminate along the edge of a metallic coil, and the opposite edge of this is laid upon a metallic surface which is connected with the other wire, the leaf of metal is inflamed, and burns with a characteristic light and color, silver giving out a bright green, and gold a whitish light. If one wire is made to terminate in a file and the other in a steel point, and the point is drawn over the file, brilliant sparks are emitted like those struck by the hammer of the blacksmith from a mass of heated iron.—Dr. Wollaston effected an important improvement in the battery in 1815, by causing each face of the zinc to be op-

posed to one of copper. The plate of the latter metal was bent round in the form of the letter U, and from the upper edge of one side an ear projected at right angles, by which it could be suspended to a cross bar of baked wood. The screw bolt which fastened it to the wood also went through a similar ear projecting in the opposite direction from the zinc plate of the next pair, the copper ear lying between the wood and the zinc ear, and both being brought into close contact by tightening the nut on the upper surface of the bar. The zinc plates lie each within one of bent copper, but without touching it in any part. Their contact is sometimes guarded against by inserting strips of baked wood between the two metals. As by this arrangement particles of zinc as they fell were caught in the bend and retarded the action of the battery, the form was afterward improved by inverting the copper plate and cutting out a portion of the top, so as to admit the bar forming the ear of the zinc plate. The slip of copper cut out was also bent to one side, to take the place of the copper ear of the former arrangement, and connect with the next zinc plate. There were, however, still other defects of serious consequence attending the operation of the battery in all these forms. The surface of the copper was diminished by the bubbles of hydrogen which collected and adhered to it. The capacity of the water to take up the sulphate of zinc diminished with the quantity dissolved, and the chemical action thus constantly grew weaker. The action of the copper was also lessened by the collection of a film of black oxide and of other impurities, and by the reduction to a metallic state of a portion of the sulphate of zinc, the latter causing local and contrary currents of electricity. These defects were corrected in the battery of Prof. Daniell, of which an account was published in 1836. The zinc in this was separated from the copper by being suspended in a porous cell, which contained the diluted acid; and this porous cell was placed in an outer vessel of cylindrical form made of copper, which acted as the negative plate, and contained a solution of sulphate of copper with an addition of about $\frac{1}{20}$ of sulphuric acid in excess. The zinc was a cylindrical rod, and the cell originally used was the gullet of an ox. In this arrangement the animal membrane admits the passage of the electric current, but checks that of the sulphate of zinc. The hydrogen, too, no longer collects upon the copper, but spends itself in decomposing the sulphate of this metal, uniting with the oxygen of the oxide, and setting the copper free. The sulphuric acid eliminated at the same time penetrates to the zinc, keeping up the strength of the mixture in the porous cell. The copper resulting from the decomposition of the salt of the metal is found to cohere upon the surface of the negative plate; and this is the principle upon which the art of electro-metallurgy is based. By keeping up a supply of crystals of sulphate of copper where they can be dissolved as required in the upper part of the solution, the

battery may be kept in action for days together. For this reason it is called the "constant battery." Its effect is increased by adding several pairs, and connecting them on the principle adopted in other batteries. Grove's battery is constructed on the principle of Daniell's, but is made much more compact by the use of platinum instead of copper. A strip of this is placed in the porous cell, which in this case is of unglazed porcelain, and contains strong nitric acid. The zinc, in the form of an open cylinder with a longitudinal slit from top to bottom for admitting the free circulation of the acid through it, is placed outside of and around the porous cell in a glass tumbler or similar vessel, partially filled with sulphuric acid diluted with 10 parts of water. The poles are thus seen to be reversed from the arrangement of Daniell's. This battery is remarkable for its intensity or power of current, but is objectionable on account of the fumes of nitrous acid generated by the reaction of the hydrogen upon the nitric acid, the gas developed at the zinc penetrating the porous cell in its progress toward the negative plate. Bunsen's battery differs from Grove's in the substitution of a cylinder of a dense form of carbon for the platinum. The coke which adheres to gas retorts answers an excellent purpose. The form of a hollow cylinder may be given to the coke by preparing it from pounded coal, and it may then be used for the porous cell by filling it with nitric acid and sand. Outside of it the zinc cylinder is placed in dilute sulphuric acid. The coke is improved by soaking it in a saturated solution of sugar and calcining it a second time. Smee's battery, like the trough battery, employs but one fluid. Its peculiarity originally consisted in the use of a negative plate with a rough surface, this having the property of shedding the hydrogen bubbles as fast as they form. The metal employed was silver coated with platinum deposited upon it in a pulverulent form. Platinum foil is sometimes used instead of silver, and the name is retained with the method of arranging the plates. A strip of the platinum is suspended with two zinc plates, one on each side of it, from a wooden bar extended across the top of a tumbler or similar vessel. The plates are kept very close to each other and exactly parallel. The two zinc plates are connected together by a clamp passing over the wooden bar, and the conductor from the platinum plate passes through the top of the bar. By keeping the plates in close proximity the electric current is rapidly excited, but it is necessary to prevent the platinum foil from being brought into connection with either zinc plate below the surface of the fluid, as may happen from the accumulation of hydrogen bubbles upon it, or from its being drawn by any other cause to one side. This may be effected by glass beads attached to its lower edge, or by its being kept in place by a weight or other means. In all these arrangements it is found that the consumption of the zinc may be greatly reduced by the application of mercury to its sur-

face, so as to form an amalgam over both faces. The metal is not then subject to dissolve in the diluted acid when the circuit is not complete; but whenever the action of the battery is required, and the communication is formed between the plates, the zinc is attacked by the acid the same as if no application of mercury had been made to its surface. The zinc is amalgamated by rubbing it with mercury after it has been cleaned with diluted sulphuric acid. It is recommended by some to mix the diluted acid and mercury together in a vial, and then apply the mixture.—The presence of a fluid is not essential to produce voltaic electricity. What is called the electric column or dry pile, first made by Behrens in 1805, and improved and brought into notice by De Luc in 1810, is constructed of disks of zinc, copper, and gilt paper, called Dutch paper; it may be less than an inch in diameter. With a column of many hundred groups piled upon one another a vibration of a brass ball suspended by a silk thread has been continued between two bells insulated and connected one with each pole of the column so as to keep a continual ringing for nearly 6 months. De Luc caused a pendulum thus to vibrate without stopping for more than 2 years. With an apparatus of 20,000 groups of silver, zinc, and double disks of writing paper, Mr. Singer obtained minute bright sparks, and charged a Leyden jar in 10 minutes with sufficient electricity to cause a disagreeable shock, to perforate thick drawing paper, and to fuse one inch of platinum wire $\frac{1}{3000}$ of an inch in diameter. The quality of the electricity was wholly that of the machine, and not that ordinarily developed by the pile. In 1812 Prof. Zamboni of Verona produced a modified form of this pile, using 2,000 disks of silver paper. Each uncoated side was covered with a layer of black oxide of manganese and honey. The outside of the column was coated with shell lac, and the whole was enclosed in a hollow brass cylinder. Between two of these columns a balanced needle was found to vibrate continuously; and attempts were made in Germany and England to apply this as a motive power for clocks and watches, but the movement was found to be too irregular to admit of this application. De la Rive recommends as a lasting form of this apparatus disks of Dutch gold and of Dutch silver paper stuck together back to back, and arranged so that a silver face lies upon each gold face, the paper separating the metallic faces of each pair. A very fine silk cord impregnated with varnish serves to secure the disks together, and the column is placed in a tube of varnished glass and supported between rods of the same. The lowermost disk is placed upon a metallic surface, and a metallic screen terminating in a ball is made to press upon the uppermost. Disks of zinc alone, one side polished and the other rough, also make a voltaic pile, similar faces being presented the same way, and separated as they are arranged in a trough only about $\frac{1}{3}$ of an inch from the opposing

polished face of the next plate. The interposed air serves as the moist conductor, and electricity is developed sensibly with the use of 60 to 80 plates, the polished face acting as the positive and the rough as the negative element. Although two metals are usually employed for generating voltaic electricity, one alone may answer, provided that different portions of it are in conditions to be differently acted on by the acid. The electrical excitement is produced with a single plate formed in part of cast and in part of rolled zinc; or if one portion of a plate of copper or of zinc is corroded and the other is clean, a current is produced, the surface most readily acted on being the generating plate. Prof. Faraday also shows that a plate presenting a uniform surface may be made to develop electrical excitement when different portions of it are exposed to the action of two fluids which differently affect it. Thus an electric current is produced when a plate of zinc, iron, or copper is put into a vessel which has been partially filled with a strong solution of sulphate of copper, and upon this a layer of dilute sulphuric acid has been carefully added. The sulphate of copper in solution will be decomposed, and metallic copper will be precipitated upon the portion of the plate in contact with it.—The presence of a current of voltaic electricity is indicated by instruments called galvanoscopes or galvanometers, the principle of which is the tendency of a magnetic needle to turn from its north and south direction when the electric current is sent through a copper wire, which passes over and under the needle in one or a number of turns. (See **ELECTRO-MAGNETISM**.) The more numerous the turns, provided the wire is of size proportional to the quantity of electricity, the more sensibly is the needle affected; and in order that the wire may be compactly arranged, so as not to transmit the current through its side to the adjoining layers, it is insulated by being wound around with silk. The needle deviates to one or the other side according to the direction in which the current is transmitted, or according to which end of the wire is connected with the positive or negative pole of the battery. By connecting a graduated circle with the needle, the amount of deviation may be made to measure the power of the electric current, and the instrument is then a galvanometer. Prof. Faraday applied another principle to the measurement of the electricity by ascertaining the quantity of water decomposed by the electric current. This he did by measuring the hydrogen and oxygen evolved, which he collected in a graduated glass tube, used as a bell glass for collecting gases. The wires of the battery ending in two platinum electrodes were introduced through the opposite sides of the tube near the bottom, and brought nearly in contact. The tube, filled with water, or water acidulated with sulphuric acid, was inverted over a receptacle of the same fluid, and as the gases collected in the upper part the liquid was displaced. The surface of this should

not be allowed to descend below the ends of the wires, as the heat then developed might cause an explosion of the gases. This apparatus was named by Prof. Faraday a voltameter. It has been modified by using two tubes set in a large cork side by side, and opening below into the vessel containing the fluid. The wires are made to terminate near each other, one under the mouth of each tube. Into the tube over the positive wire oxygen only is evolved, while the other receives only hydrogen in quantity double that of the oxygen. Other forms of voltameters have also been devised, the principle of which was the determination of the amount of heat developed. This was estimated by its effect in causing the elongation of a wire of platinum, or in causing narrow slips of metal laid up together to twist still more or to untwist by their unequal expansion or contraction.

ELECTRO-MAGNETISM AND MAGNETO-ELECTRICITY are branches of science which treat of the phenomena belonging to both electricity and magnetism. In our article on electricity we have given an exposition of the facts of this branch of science, independent of any hypothesis as to the causes of the phenomena; but our account would be incomplete, and it would be almost impossible to present a proper view of the branches above mentioned in the space to which we are limited, were we not to give some idea of the generalizations which have been invented to explain the phenomena, and to express the laws of their mutual connection and dependence. It must be recollected that science does not consist in an accumulation of facts, but in a knowledge of principles, and it is impossible to arrive at a full comprehension of these principles without expressing them by means of some hypothesis from which logical deductions can be made, which will enable us at any time, independently of mere memory, to say what result will be produced when the conditions are known, or in other words, which will not only present to us the relations of known phenomena, but enable us also to predict the occurrence of those which have not been observed. Without hypotheses of this kind no extended and definite progress can be made in science. It should, however, always be borne in mind that they are the provisional expressions of the generalizations of our knowledge at a given time, and that we must hold ourselves in readiness to modify or even abandon them, when we meet with facts with which they are decidedly inconsistent. Two hypotheses have been proposed to account for the phenomena of electricity: one, that of Du Fay, known by the name of the theory of two fluids, and the other by that of the Franklinian, of one fluid. According to the first, all bodies are pervaded by two elastic fluids, the atoms of each repelling those of the same kind and attracting those of the opposite kind. When the two fluids are together in equal quantities in the same body, they neutralize each other; but when separated by friction or other means, their attractions and repulsions are

manifested by various electrical phenomena. The second hypothesis supposes that all the electrical phenomena are produced by the disturbance of one highly elastic fluid, which pervades the earth and all material bodies, and which is able to move with various degrees of facility or not at all through the pores of substances of different kinds of gross matter, which are hence considered either conductors or non-conductors; that the atoms of this fluid repel each other with a force varying inversely as the square of the distance; that the atoms of the same fluid attract the atoms of gross matter, or some ingredients in it, with a force varying in accordance with the same law; that the atoms of gross matter devoid of electricity tend to repel each other with a force inversely as the square of the distance. When any body has so much electricity combined with it that the self-repulsion of its atoms is just balanced by the attraction of the same atoms for the unsaturated matter, then the body is said to be in its natural state. So long therefore as all portions of space contain their natural share of the fluid, no electrical phenomena are exhibited; but if, by means of friction, chemical action, heat, and other agencies, together with the interposition of partial or non-conducting substances, the electricity is accumulated in one portion of space, and rendered to the same amount deficient in another, then two classes of phenomena are manifested: 1, those called statical, such as induction and the consequent attraction and repulsion of light bodies, due merely to the accumulation or deficiency of the fluid; 2, dynamical, or those which arise from the transfer of the fluid from the place where it is redundant to that where it is in deficiency. Our countryman, Franklin, is justly celebrated for his discoveries in science, but his claims to philosophic genius rest particularly upon his conception of this theory of electricity, which bears his name, and which, with slight modifications and additions, is still sufficient to express the connection and relation of the multiplicity of facts which have been discovered since his day. However different the two theories at first sight may appear, their mathematical expression and the deductions from them do not differ, provided that we adopt the modification of the latter proposed by *Æpinus* and Cavendish, that matter devoid of electricity repels matter; an assumption not inconsistent with the attraction of gravitation and chemical action, since we may refer even these to the same cause. The theory of Du Fay was generally adopted by German and French savants, because it was first discussed by them in a mathematical form. The theory of Franklin was afterward developed mathematically, and with the modifications we have mentioned, is, we think, more readily applicable to the facts of the present state of the science than the other. It follows from the theory of Franklin that if electricity be communicated to a sphere of conducting matter, all the fluid will be found at the sur-

face, because each atom repels the other, and the state of equilibrium will be that of an equal distribution at the circumference; the atoms are prevented from flying into space by the non-conducting medium of air in which the globe exists. In like manner it follows from an application of the law of attraction inversely as the square of the distance, that when a body has less than its natural share of electricity the deficiency must exist at the surface. In charged conductors of elongated forms, the distribution of the fluid will be greater at the two extremities. The phenomena of the Leyden jar are readily deduced, and all the facts connected with it may be anticipated even with numerical exactness, by the application of this theory. When a redundancy of electricity is thrown on one side of a pane of glass, the repulsion acting through the glass will drive off a portion of the natural electricity on the other side, the unsaturated matter of which will attract the free electricity thrown on the first side and thus neutralize its repulsive energy; and in this way an immense amount of electricity can be accumulated in a small space. When the two surfaces are joined by a conducting circuit a discharge takes place with great intensity, because the fluid on the charged side is impelled through the circuit by the repulsion of its own atoms, and because it is attracted to the other side by the unsaturated matter. If an insulated conductor in the form of a long cylinder with round ends be brought near a charged conductor, but not within striking distance, the natural electricity of the former will be repelled to the further end; the end nearer the charged body will be in a state of deficiency of electricity or negatively electrified, while the further end will be in a state of redundancy or positively electrified. Between the two ends there will be a point which will be neutral or in its natural state. The intensity of this action diminishes rapidly with the distance, particularly in the case where the cylindrical conductor is short and the excited body is small; but in the case of atmospherical electricity, in which the charge is on the surface of a large cloud, the inductive action takes place through several miles of intervening space. An attempt was made by *Æpinus*, *Poisson*, and others, to apply the same hypothesis to the phenomena of magnetism. Between these and those of electricity a striking analogy was observed. For example, bodies which are dissimilarly electrified attract each other; those which are similarly electrified repel each other. In like manner, two similar poles of a magnet repel, and two dissimilar poles attract each other. Again, if the north pole of a magnet be brought near an unmagnetized bar of soft iron, the near end exhibits southern polarity and the further end northern polarity, apparently similar to the result of the action in the example we have just given of electrical induction. There is however this remarkable difference, that if we magnetize a piece of hardened steel in the same

way by the induction of a powerful magnet, and afterward break the bar into two pieces, each half will exhibit a north and south pole of equal intensity; and if we continue to break each piece into two others, however far the division may be continued, the same result will be produced, namely, a pole at each end of each piece and a neutral point in the middle. From this experiment we infer that the polarity of magnetism results from the development of the magnetic power in each atom of the mass; while if the same experiment be made with an electrical conductor, that is, if it be separated into two parts while under the influence of the excited body, each half will exhibit a charge of only one kind of electricity. By considering therefore that electrical conduction produced by a bodily transfer of the fluid from one end of the conductor to the other, and limiting the disturbance in magnetism to the particles of gross matter, a mathematical expression of most of the phenomena known previous to the discovery of *Oersted* was obtained. Still electricity and magnetism were so dissimilar in some particulars that they continued to be studied as distinct branches of science. The fact had long been noticed that discharges of lightning frequently gave polarity to bars of steel, and in some cases reversed the mariner's compass. A series of experiments to imitate these effects were made by *Franklin* and others by passing shocks through darning needles. The results were unsatisfactory, since the needle was sometimes magnetized in one direction and sometimes in the other, and frequently not at all, without any apparent change in the conditions. Indeed, ordinary electricity was not favorable to the study of the connection of electricity and magnetism, since the phenomena which belong to both are exhibited during the continuance of an electrical current; and in the case of the discharge of a Leyden jar the transfer is so instantaneous that we are only able to study effects which have taken place, without being able to make any observations as to the manner in which these results have been produced. This was the condition of the science up to the winter of 1819-'20, when *Prof. Oersted* of *Copenhagen* put a new interrogation to nature by asking what would take place in regard to a magnetic needle when the two poles of a galvanic battery were joined together by a conducting wire. He found that when the wire was brought parallel to and near the needle, the latter tended to turn at right angles to the former. This was a new result, unlike any phenomenon before discovered. Previous to this, the connection between electricity and magnetism had been sought in the analogy of the polarity of the two ends of a magnetic bar and the two extremities of a galvanic battery, both of which exhibited polarity. An account of this remarkable discovery was published in all parts of the civilized world, and everywhere excited the interest of men of science. It was repeated in *England*, *France*, and *Germany*. The additional fact was discovered

by Arago in France and Davy in England, that the wire joining the two poles of a galvanic battery while the latter was in action was capable of imparting magnetism to iron filings; but the person who seized on the phenomenon with the greatest avidity, and who in the course of a few months developed the whole subject to such an extent as to elevate it to the rank of a new science, was Ampère, of the French academy. He discovered an additional fact which gave a key to all that had previously been found by his contemporaries, namely, that two parallel wires transmitting currents of electricity in the same direction attract each other, while similar wires transmitting currents moving in opposite directions repel each other. On this fact, combined with the hypothesis that all magnetic action consists in the attraction or repulsion of electrical currents, he founded his celebrated theory of electro-magnetism, which gives in a single sentence a generalization from which all the known phenomena of electro-magnetism as well as ordinary magnetism can be deduced. This theory is based upon one fact and one hypothesis. The fact is this, that currents moving in the same direction attract, and moving in opposite directions repel, each other; the hypothesis is, that the magnetism of a bar of steel consists in currents of electricity revolving at right angles to the length of the bar around each particle of the metal. In order to give as much precision to our ideas as is possible without the use of diagrams, let us suppose a number of shillings or cents piled one on the other, and cemented together so as to form a cylindrical column or rod 8 or 10 inches in height; and let us further suppose that on account of some molecular action a current of electricity is perpetually circulating in the circumference of each piece of coin, and that the direction of the currents is the same in the whole series. If we further suppose that the column is standing on end, and that this motion is contrary to that of the sun and contrary to that of the hands of a watch when placed face upward, such arrangement will represent the hypothetical magnet of Ampère, in which the north end, or that which turns to the north, is uppermost, and consequently the south pole undermost. If these postulates be granted, instead of loading the memory with an almost infinite variety of disconnected facts, we shall have at once a generalization from which all the phenomena can be deduced at pleasure in a series of logical corollaries. If this theory be true, or if it be even an approximation to the truth, it will follow that if currents of electricity be transmitted through an arrangement of the kind we have described, the phenomena of ordinary magnetism will be exhibited; and this anticipation will be realized if we coil a piece of copper wire covered with silk into the form of a corkscrew spiral, forming a cylinder 8 or 10 inches long, and if the two projecting ends not included in the spiral be passed backward through the cylinder and made to project from the middle at

right angles to the length of the cylinder on opposite sides. If this cylinder, the several spires of which will represent the pieces of money, be supported horizontally, so as to turn freely as a magnetic needle moves on its pivot, it will take a north and south position when a powerful current of galvanism is transmitted through the wire. Nay, more, another cylinder formed of like spires through which a current of galvanism is passing will act upon the first precisely as a magnet would act upon another magnet. Indeed, so long as the galvanic current is passing through this helix or spiral, it exhibits all the properties of an ordinary magnet; but they immediately disappear when the current is interrupted. To deduce from his theory the almost infinite number of facts which it involves, Ampère first considered the action of currents on currents. Starting with the hypothesis that the attraction and repulsion were inversely as the square of the distance between the elementary parts or smallest portion of the currents, he deduced mathematically the consequence that the force of a current of considerable length acting on a single element of a current would vary inversely as the simple distance; and this he was enabled to verify by experiment by suspending a bent wire, through which a current was passing so as to be free to oscillate under the influence of a single element, which was ingeniously effected by doubling a piece of covered wire in the middle of its length, thus \angle . When a current was passed through this double wire, the portion of it which went to the point of bending and that which came from it neutralized each other, and the residuary effect therefore was that of a single point, which gave a result exactly in conformity to the deduction from the theory. After proving experimentally this fundamental principle, he was enabled by mathematical reasoning, principally of a simple character, to deduce the resultant action of the most complex forms of conductors upon conductors. Among many others, the following important deductions immediately flow from the premises assumed. If a current of electricity be sent in the direction from A to B through a straight conductor, A B, of indefinite length, placed for example horizontally, and a current be sent downward through a terminated conductor, C D, perpendicular to the former, the latter conductor will be impelled parallel to itself along the length of the horizontal conductor. This effect will be due to the fact that on the right side of the short conductor the elements of the two currents are moving in opposite directions; the current in the short wire is approaching the point F, while the current in the horizontal wire is moving from this same point, and hence on this side repulsion will take place; while on the left hand side of the short wire the two currents are moving toward the same point, and therefore attraction will be exhibited; and under the influence of these two forces, the

short conductor will move parallel to itself from right to left along the horizontal conductor. If the direction of the current in either of the two conductors be reversed, the motion of the short conductor will also be reversed. If, instead of the short conductor, one in the form of a ring be freely suspended over the long conductor, with the plane of the latter across the former, the current passed through this will ascend on one side of the ring and descend on the other. Therefore, the one side will tend to move to the right and the other to the left, and the resultant action will be to bring the plane of the ring parallel to the horizontal current; in which case the current in the lower part of the ring will be moving in the same direction as the current in the long wire. Now, since, according to the theory of Ampère, magnetism depends upon currents of electricity, it follows that the magnetism of the earth results from currents of electricity revolving continually from east to west. Hence, if a conductor be bent into the form of a ring or hoop, and freely suspended, it will arrange itself east and west. To insure the success of this experiment, the hoop should be formed of a long wire covered with silk and coiled into the form of a ring so as to multiply the actions. Such a ring may be considered as one of the disks represented by the shillings in the hypothetical magnet; and since each disk making up the whole length of the rod would be similarly acted upon by the currents of the earth, the axis of the rod would assume a north and south direction if left free to move, thus affording an explanation of the fact, so long considered an ultimate one, of the directive property of the needle. Let us return again to the action of the long horizontal conductor on the short perpendicular one. If the former be bent into a horizontal circle, then it is evident, from the reasons we have before given, that the short conductor, moving perpetually round it parallel to itself or retaining its perpendicular position, will describe a circle. This may be shown experimentally by bending a piece of wire into the form of an Ω , and supporting it vertically on the point of a perpendicular wire which fits lightly into a socket on the under side of the middle of the arch. If the two ends of this bent wire dip into a circular basin of mercury through the middle of which, surrounded by a glass tube, the supporting pointed wire passes, and if a powerful current of galvanism be sent up through this wire, it will descend through the legs of the Ω into the mercury; and if at the same time a powerful current be passed through a ring or hoop conductor placed horizontally around it, a rapid rotation of the Ω -formed wire will take place. Now since magnetism, according to the theory we have adopted, consists in currents of electricity revolving at right angles to the magnet, if a magnetized bar be introduced within the branches of the bent conductor, a similar rotary motion will ensue. This fact was first shown experimentally by Mr. Faraday. It is, however, a logical consequence of

the theory of Ampère, and might have been deduced from it. A beautiful illustration of the phenomena of terrestrial magnetism was first exhibited by Prof. Barlow of Woolwich, England. He prepared a wooden globe, into the surface of which a long conductor was buried in a spiral groove extending with many turns from pole to pole. This globe was afterward covered with paper, on which were drawn the continents and oceans. When a small dipping needle was placed over this apparatus and a current of galvanism sent through the concealed conductor, the needle assumed a direction similar to that which would be due to an analogous position on the earth's surface; and since, in all cases, the needle tends to arrange itself at right angles with the direction of the current, by a proper adjustment of the conducting wire in the groove the variation of the needle at every point of the earth's surface could be accurately represented. The explanation of all the phenomena of ordinary magnetism readily flows from the same principles. We have stated that if a magnet be broken in two, each half becomes a separate magnet, exhibiting north and south polarity. If the hypothetical magnet which we have illustrated by a pile of shillings be broken in the same way, each part will become a separate magnet; the two ends of the two parts which were previously in contact will attract each other, because the currents will be revolving in the same direction, but if we turn the other end of one magnet to the same end of the other, repulsion will ensue, because the currents are revolving in different directions. By a little reflection it will not be difficult to explain or to anticipate the action of the two magnets on each other under any assumed condition. In adopting this hypothesis, it is not necessary to contend for the actual existence of electrical currents in the magnet or even in the earth. It is sufficient to assert that all the peculiarities of the known phenomena of magnetism are precisely such as would result from an assemblage of currents such as Ampère has supposed to exist. It is probable that in the phenomena of magnetism a molecular distribution of the fluid takes place which is analogous to that in a wire transmitting a current. Indeed, we know that at the moment of magnetizing a bar of iron, a molecular change is produced in the metal of sufficient intensity to cause a sensible sound; a fact which was first noticed by Prof. Charles G. Page of Washington.—It is an interesting fact in the history of science, that discoveries in one branch serve to throw light on other branches, and in many cases to furnish instruments by which actions too delicate to be appreciated by ordinary means may be exhibited and measured. Soon after the discovery of Oersted, Prof. Schweigger of Germany covered a long wire with silk and coiled it into the form of a rectangle, within which he suspended by means of a fibre of silk a magnetic needle. When a very feeble current of electricity was sent through this conductor, each turn of the

wire acted on the needle to turn it at right angles to its own direction; and in this way an instrument called the galvanometer was produced, by which the most feeble galvanic action in the form of a current is exhibited. It has been before stated that Arago and Davy discovered that the conducting wire through which a galvanic current is flowing is capable of inducing magnetism in iron filings. They also showed that a discharge of ordinary electricity, when made above or below a sewing needle, gave it definite polarity; and in this way the reason of the failure of Franklin and others, who had attempted to magnetize steel wire by ordinary electricity, was explained. In these attempts the electricity was sent through the length of the needle, instead of across or around it, as the theory of Ampère would indicate. Mr. Sturgeon, in England, was the first to construct an electro-magnet, which consisted of a piece of iron wire bent in the form of a horse-shoe, insulated with a coating of sealing wax, over which was loosely coiled a few feet of copper wire. When the current was sent through the latter, the iron became magnetic, and exhibited in proportion to its size a very intense action. The first person, however, who exhibited the great power of the galvanic current in producing magnetic effects was Prof. Henry of Washington. He found that by surrounding a large bar of iron bent into the form of a horse-shoe by a number of coils of wire, so connected with the battery of a single element that the current in each wire would move in the same direction, a magnetic power of astonishing magnitude could be produced with a comparatively small galvanic apparatus. A magnet constructed on this principle, now in the cabinet of the college of New Jersey, will readily support 8,500 lbs. In order, however, to produce a maximum effect of this kind, it is necessary that great care be taken in the insulation of the wires, that there be no cutting across from one wire to another; and for this purpose the ends of two wires intended to be soldered to the positive pole of the battery should project together, while the two ends intended to be united to the negative pole of the battery should also be associated. If the magnetic power of the iron is to be developed by means of a compound battery, then a single long wire may be employed instead of a number of short ones. The power of the electro-magnet depends on the following conditions: on the energy of the current, the dimensions and form of the iron, the nature of the iron—the softer the better—the perfect insulation of the wire, and the proper adjustment of the length of the wire to the intensity of the battery. By means of an electro-magnet of the kind we have mentioned, the instantaneous development of an immense magnetic power is produced, by which discoveries have been made in regard to this mysterious agent, of the highest interest. Prof. Faraday has shown by the application of this instrument, that magnetic property is possessed by all bodies, either in the

form in which it is ordinarily developed, *i. e.* in the direction of the greatest length of the body, or at right angles to this length. He finds, for example, when different substances are made into bars and suspended by means of a fibre of silk between the poles of a powerful electro-magnet, that they arrange themselves with the longer axis in the direction of the pole or with the shorter axis in the same direction. Bodies of the former class are called magnetic, those of the latter class are called diamagnetic. This property is even possessed by gases. (See DIAMAGNETISM.) An electro-magnet even of immense power can be magnetized, unmagnetized, and remagnetized in an opposite direction, by instantaneous changes in the direction of the current of the galvanic battery. The large magnet we have mentioned as at Princeton can be loaded with several hundred pounds, and while in this condition may be so rapidly unmagnetized and remagnetized with the opposite polarity that the weight has not time to commence its fall before it is arrested by the attraction of the reverse magnetism. This sudden change of polarity affords a means of producing mechanical movements of considerable power through the agency of electro-magnetism, which have by some been considered as a rival to steam power. The first machine moved by this power was invented by Prof. Henry immediately after his experiments in developing electro-magnetism, and an account of it was published in the "American Journal of Science" in 1831. It consisted of an oscillating iron beam surrounded by a conductor of insulated copper wire. A current of electricity was sent through this in one direction, which caused one end to be repelled upward and the other attracted downward by two stationary magnets. The downward motion of the one end of the beam near its lowest point brought the conducting wires in contact with the opposite poles of the battery, which produced the reverse motion, and so on continually. In a subsequent arrangement, the velocity of motion was regulated by a fly wheel, and electro-magnets substituted for the permanent magnets at first used. Prof. Ritchie of the London university afterward produced a rapid rotatory motion between the two legs of an inverted horse-shoe magnet in a piece of iron around which a current of electricity was made to revolve, and the magnetism reversed at each semi-revolution. Modifications of these two forms of the apparatus have since been made in almost every part of the civilized world. A large electro-magnetic engine was constructed by Prof. Jacobi of St. Petersburg by which a small boat was propelled at the rate of several miles an hour. But the largest and most efficient engine of this kind was constructed by Prof. Page of Washington, at the expense of the U. S. government. It exhibited sufficient power to propel with considerable velocity a railway car, and afforded the best means which has yet been presented of estimating the comparative cost of the application of electricity as a motive power. From all the experiments which have

been made, it appears that though the electro-magnetic power can be applied with less loss in the way of effective work than heat by means of the steam engine, yet the cost of the material by which it is generated is so great that it cannot be economically employed. According to the experiments of Despretz, one pound of coal in burning develops as much heat as 6 pounds of zinc; consequently, under the same conditions, 6 times as much power is developed from the burning of an equal weight of the former as from that of the latter. Now the power of the steam engine is produced by the burning of coal in air, while that of the electro-magnetic engine is developed from the oxidation or burning of zinc in acid; and since coal and air are the simple products of nature, while zinc and acid require artificial preparation at the expense of power, it must be evident from all these considerations that electro-magnetism cannot compete with steam, although it may be applied in some cases where the expense of materials is of secondary consideration. Electro-magnetism, for example, is applied with much success in calling into operation power at a distance, as in the case of the electro-magnetic telegraph, in giving simultaneous motion to the hands of clocks situated in different parts of a city, in measuring very minute portions of time, and in bringing into action the power necessary to ring alarm bells.—For an exposition of the scientific principles of electro-magnetism, we would refer to De Montferrand's work on the subject, translated from the French by Prof. Cumming of Cambridge, England; and for various ingenious modifications of apparatus, and interesting facts of the science, to Dr. Page's papers in the "American Journal of Science and Art." (See MAGNETISM, and MAGNETO-ELECTRICITY.)

ELECTRO-METALLURGY, ELECTROTYPING, called by the French *galvanoplastie*, the art of separating the metals from their solutions and depositing them in solid form by means of the electric current, excited by the voltaic battery or magneto-electric machine. The object is to obtain in a metallic layer an exact copy of any surface, as of the impression made in wax of an engraving, a page of type, a medal, coin, &c., the filling of which impression in metal produces a duplicate of the original article, or may itself be used as a mould for obtaining in more fusible metal casts of the same. The metal may also be precipitated so as to adhere permanently upon the surface of objects, either for the purpose of ornamenting, strengthening, or protecting from different agents of change. This branch of the art is called electro-plating and electro-gilding. The discovery that metals might be thus deposited soon followed that of the voltaic pile. Wollaston coated silver with copper by this method in 1801, and Brugnatelli described in 1805 his gilding 2 silver medals in the same manner; but it was not until Mr. Thomas Spencer of Liverpool made his experiments in 1837, that any prac-

tical importance was attached to the operation. He had observed that a copper coin used as the negative plate of the battery became incrustated with a layer of copper derived from the solution of blue vitriol in which it was immersed, and that every mark upon the coin was transferred in reverse upon the new layer. But when at another time a slip of the same metal, which he used for the negative plate, happened to be protected by a few drops of varnish from receiving the metallic deposit, it occurred to him that a plate might be thus entirely covered, and any design be cut through the varnish, and the copper be deposited only on the lines thus exposed. He succeeded on trying the experiment, the copper plate being immersed in a saturated solution of sulphate of copper, and connected by a wire with a bar of zinc, which was placed in a dilute solution of sulphate of soda. This was contained in a large glass tube, which (its lower extremity being closed with a porous stopper of plaster of Paris) was introduced into the sulphate of copper solution. About the same time Prof. Jacobi of St. Petersburg was conducting a similar class of original experiments, an account of which, presenting similar results, was published in England in 1839. This drew forth a letter from Mr. J. C. Jordan, a printer, which was published in the "Mechanics' Magazine" of June, describing his method of obtaining impressions from engraved plates, matrices from types, &c., and suggesting other applications of the same process, as obtaining casts from a plaster surface, and even of making metallic tubes by precipitating a metal around a wire, and then dissolving this out by heat or some solvent which has no action upon the outer coating. With such an introduction the art was soon taken up by practical men, and rapidly perfected, so that it is now extensively applied to minister in a great variety of ways to the wants of mankind. The apparatus originally employed is distinguished as the simple form of the decomposing battery, in which the electric current is generated in the same vessel wherein the metal is deposited. It was improved by substituting for the inner vessel of glass one of unglazed porcelain or earthenware, which stands in the centre of the outer cylindrical vessel, and contains, in the sulphuric acid diluted with 12 or 15 times its weight of water, the zinc plate suspended by a brass wire and soldered to it, the wire curving over and sustaining at its other end the object to be coated, which is hung face to face with the zinc plate. Neither the zinc within the porous cylinder nor the object without quite touches its walls. As the zinc is dissolved, about the same amount of copper is separated and deposited upon the electro-negative pole. It tends to gather most near the point where the wire is attached to the object, and therefore we should have several of these points of attachment, and all the conductors should be themselves protected by a coating of varnish, as also those portions of the object which it is not designed to cover with the

precipitated metal. As the sulphate of copper solution would soon be reduced in strength, it is well to keep a bag of crystals of this salt suspended in the upper part of the solution, the lower portion always retaining more strength than the upper. A convenient substitute for this arrangement is to take a tight wooden box or trough, and divide it by a partition of some porous material, as a thin board of sycamore, into two parts, in one of which the copper solution is placed, and in the other about the same quantity of a solution of sal ammoniac, with free crystals of the salt to supply the waste caused by the action of the zinc. A plate of this metal is suspended by wires soldered to its edge and passing over a stick laid across the top of the box, and so adjusted that the plate shall face the diaphragm or partition and be very close to it. The object to be coated is suspended upon another stick parallel to the first by the same wires passing over it. The apparatus should be left several days for the operation to go on; but there is no objection to taking out the plates occasionally to observe how it proceeds. In electro-plating, constant motion is recommended to insure uniformity of deposition. The probability of obtaining a deposit of equal thickness is increased by having the surfaces of the two plates perfectly parallel to each other, and of about the same size and shape. The tendency is for the most prominent points to receive the greatest thickness of metal. The object of the partition is to keep the two salts apart while the electric current may pass freely through the diaphragm. The zinc salt generated in the process is also prevented by it from going to the negative plate and incrusting this with the reduced metal, as it is disposed to do when only one vessel is used, thus checking the operation or interfering with the production of a perfect mould. Cohesion of the precipitate is prevented by a previous application to the object of a thin layer of some greasy substance, and then removing all that can be taken up with a fine linen rag. A much better method has been devised in this country of first applying a coating of silver, and then washing this with an alcoholic tincture of iodine. This prevents cohesion of the metallic surfaces without interfering in the slightest degree with the process of deposition. But in plating or gilding, the greatest care is required to remove by boiling in caustic alkali and thorough washing every trace of grease, and render the articles perfectly bright. —The form of the battery usually employed in electrotyping requires two vessels, in one of which the electric current is generated, and in the other, which corresponds to the decomposition cell, the articles to be acted upon are suspended in the metallic solution. A Smee's battery may conveniently be used for generating the current, and a wooden cistern to contain the solution of sulphate of copper. The objects to be coated are suspended from a metallic rod resting upon the two ends of the trough near one edge, and a copper plate is suspended so as to

face these objects a little distance off toward the other side of the trough. The rod being connected with the zinc plate, and the copper with the platinum of the battery by brass wires, the circuit is complete, and the deposition immediately goes on. A battery of novel construction is described by Prof. Jacobi of which an account may be found in the article *Galvanoplastie* of the *Dictionnaire des arts et des manufactures*. It is called the pile of Prince Bagration, and surpasses all others in the regularity of its action, its extreme simplicity, and the little care it requires. It will continue in operation more than 6 weeks without attention, demands no skill or experience in chemical manipulations, and costs a mere trifle. Jacobi thinks its discovery must have an important effect upon the art of reducing ores, and throw light upon many obscure subjects connected with industrial operations. A flower pot or any such vessel impervious to water is filled with earth saturated with a solution of sal ammoniac. In this a plate of copper and another of zinc are placed a little distance apart, and wires are attached to them. A voltaic pair of simple form is thus obtained, which may be kept in action for months or even for years, if the earth is occasionally moistened with the solution and the zinc plate is removed when it is at last worn out. It is well to leave the copper plate for a few moments in a solution of sal-ammoniac before putting it into the earth, and let it dry until a decided oxidation appears upon its surface. By uniting several pairs a constant current is obtained, long continuing and perfectly regular in its action, which may be employed for various purposes; as for example, to reduce metals to their most malleable form. Jacobi made use of a battery of 24 pairs. He recommends that the vessels containing the pairs should be carefully isolated. The subject is strongly commended to the attention of those engaged in electrotyping, not merely for its economy, but for its entire freedom from the noxious vapors which are given off from batteries requiring the use of nitric acid.—In the use of the batteries the metallic deposition is obtained in different conditions, which vary with the intensity of the current, the strength of the acid solution, its temperature, &c. To obtain the copper in a clean metallic state, the solution of the sulphate must be acidulated with sulphuric acid, and be kept well saturated by constant supplies of fresh sulphate of copper, or by sufficiently large copper plates. There should also exist a proper relation between the zinc and the acid which acts upon it, and the object to be coated. If the zinc plate be large and the object very small, the copper is likely to be of brittle texture, or it may be deposited in the form of a powder if the difference be considerable. If the sulphate of copper solution becomes nearly exhausted, or the electric current is disproportionately strong, or the positive pole disproportionately large, the copper is likely to be separated in the form of a black

powder, with the collection of much hydrogen upon the negative plate. This tendency may be corrected by one or another of the following means, as recommended by Smee. The intensity or quantity of the battery may be lessened; the negative pole may be increased or the positive reduced in size; the solution may be saturated, or it may be rendered neutral; or lastly, the temperature may be lowered. The process succeeds best at a temperature not lower than 60°. By properly regulating the operation, copper plates may be obtained suitable for printing engravings from, which will wear quite as well as the original metal; but the method as now practised is not to obtain the whole thickness of the plates by the electrotpe operation, for a very thin surface of copper is sufficient to preserve the exact impression, and this is more economically backed with some cheap alloy. An inferior quality of type metal answers this purpose very well; it melts readily, and may be made to cohere to the copper facing by simply pouring a layer of it over the thin sheet, which is laid flat upon its face on a smooth hard surface upon which it is firmly secured by elastic slips of steel extending from its edge to a fixed object a little above. The back of the copper more readily unites with the alloy if it has been previously coated with tin by pouring this metal when melted over its surface, as the sheet is held in an inclined position. It is this process which is employed in electrotyping the pages of this work. Every page of type, after it has been used for furnishing proofs, is impressed upon a surface of wax. This is then covered with plumbago in fine powder, and all the superfluous powder is blown off or brushed away in an apparatus constructed with fine brushes for this purpose. By the application of this conducting medium every portion of the wax face is made capable of receiving the coating of copper, when the cake is encircled by wire and suspended by it to the rod connected with the zinc plate of the battery. The metal as it is deposited enters into the most minute depressions and retains the most delicate markings as distinctly as they appear in the wax. The page of type being thus duplicated, the members that composed it are at liberty to be distributed for the combination of new pages; and thus a single fount may be kept in continual use for the setting up of series of works, of which copies or editions may be struck off as they are wanted. The thin sheets of copper are backed with a kind of type metal, and the plates are then planed upon the edges and back by sharp knives, by which they are brought into proper shape and thickness. Electrotyping is preferred to the ordinary method of stereotyping, or taking a cast in type metal of the impression of a page of type made in plaster of Paris, for the reasons that the stereotype is more subject to defects, does not present so sharp an outline of the letters, and is less durable than the copper-faced electrotpe. The battery employed by the printing

house engaged upon this work is of unusual dimensions. The decomposition cell is a cistern of wood, 12 feet in length, 2 feet in width, and 3 feet deep. It contains about 538 gallons of an acidulated solution of sulphate of copper, which is kept for years of uniform strength by the sheets of copper suspended in it opposite to each surface exposed for the reception of a metallic coating. The objects to be electrotyped are placed in the solution in the evening and taken out in the morning. They are suspended on brass rods which lie across the top of the cistern; one end of each rod is turned over at right angles to form a short foot, which dips into a channel of mercury that extends along the outer edge of the cistern. This basin is formed by turning over the upper edge of a broad sheet of copper that is attached to the side of the cistern, and extends beyond it to the other cistern forming the battery, where the same sheet of copper is again turned up to make another channel for mercury into which the poles of the zinc plates are introduced on one side. Those of the platinized copper forming the other pole of the battery dip into another corresponding channel of mercury on the other side of the battery cistern, through which connection is made in the same manner on that side with the decomposition cell, other brass rods standing with one foot in this channel supporting the sheets of copper which are suspended in the solution to complete the circuit and furnish the metal for the deposit. The battery is constructed with plates of amalgamated zinc alternating with others of platinized copper, each plate measuring 10×14 inches. They are let down in grooves cut on each side of the cistern, their lower edges not reaching within some inches of the bottom. According to the amount of work to be done, the number of plates is reduced or increased; 18 or 20 of each are ordinarily in use. The acid employed as the exciting liquid is the common sulphuric acid. —A variety of substances are employed beside wax for obtaining moulds of medals and other small objects for electrotyping. Fusible metal made by melting several times 8 parts of bismuth, 5 of lead, and 3 of tin, is well adapted for this purpose. Another fusible alloy used by the French for their *clichés* moulds consists of 8 parts of bismuth, 4 of tin, 5 of lead, and 1 of antimony. The medal is set in a block of wood, and just as the metal, which is poured in a shallow box lined with smooth cartridge paper, is on the point of setting, the medal is laid upon it, and struck gently so as fairly to impress its surface. If any oxide is formed on the surface of the alloy, it should be skimmed off with the edge of a card. Plaster of Paris is also employed for the same purpose; and gutta percha is found to be well suited for it. The latter is softened at the temperature of boiling water, and pressed upon the medal, which is surrounded with a metallic rim. When cold the gutta percha is found, if the process is well performed, to have received an admirable impression. This is treated like

the wax to render it susceptible of receiving the metallic coating. Powdered zinc is sometimes mixed with the fine plumbago to increase its conducting power. The zinc is melted in an iron ladle, and when just ready to take fire, a few pieces of iron are dropped into it. When cold, the mixture is easily pulverized.—Electrotyping may be applied to the preservation of various delicate objects by coating them with a metallic deposition. Insects and delicate flowers are made conductors by dipping them in a weak solution of nitrate of silver, and then precipitating the silver upon every portion of them by exposure to the vapor of phosphorus, or sulphurous acid gas, or even to the action of the light. Cloth of different kinds has thus been coated with a metallic covering, and lace has been beautifully gilt and ornamented. A sheet of copper, precipitated upon a surface of morocco of any desired pattern, may be used for embossing the surfaces of other skins. Copies of daguerreotype pictures have been taken by this process. A conducting wire of broad surface being soldered to the back of the picture, and the portions not intended to be coated being covered with wax, the plate is put into the solution of sulphate of copper, precisely as if it were a medal to be electrotyped. The deposit is removed when sufficiently thick, and the copy, which is wonderfully exact, is often found to present a softer and finer expression than the original. The face of the picture may be gilded by subjecting it to the action of a very feeble electric current in a weak solution of cyanide of gold and potassium. In applying the process to the incrusting of fruits, leaves, and similar organic substances, for the purpose of preserving their forms, either in the metallic shell deposited upon them or by making use of this as a mould for restoring the object in solid form, the body is first covered with the plumbago powder, and a pin is inserted at one extremity by which it is supported upon the wire of the battery connected with the zinc plate. The pin, after the operation is completed, is withdrawn, and through the hole it leaves the fluids of the fruit may be expelled by heat. Bronze statues are made from the hollow plaster casts obtained from the original model in clay; these casts, which may be in several sections, being coated with plumbago powder, and exposed to the sulphate of copper or a bronze solution. The sections thus obtained are fitted and soldered together, and electrotyped over the soldered joints.—Electro-plating is the covering of articles by the electric current with a coating of silver. It is very extensively practised for giving to ware made of cheap alloys, as britannia metal, German silver, pewter, or brass, the beauty and excellence of silver ware, at the cost of a very thin coating of the more expensive metal. The solution of silver has formerly been obtained by dissolving the metal in dilute pure nitric acid; distilled water is afterward added, and the silver is precipitated as a cyanide by a solution of cyanide of potassium. The silver precipitate, being collected and well washed, is

dissolved in a solution of cyanide of potassium, and this is the fluid used in the place of the sulphate of copper solution employed for the deposition of copper. But a more convenient mode of obtaining the solution is to connect a plate of silver with the positive pole suspended in a solution of cyanide of potassium, and allow the current to pass until the silver begins to deposit rapidly upon the negative pole. To insure the cohesion of the silver upon every portion of the surface exposed, the latter must be thoroughly cleansed, which is best effected by boiling the articles in an alkaline ley, then dipping them into nitric acid, and finally scouring them. The copper wire is then attached to any portion, or wound around the body, and this being again dipped for an instant in nitric acid is then suspended to the metallic rod which connects with the zinc plate of the battery, its surface opposed to a plate of silver connected with the other pole; after being in the solution a few seconds, and receiving the first coating of silver, the article is taken out and rubbed with a hard brush and a little fine sand. It is then replaced and left for several hours in the solution, when it acquires a coating as thick as tissue paper, of a dead white silver. It may be then polished with a hard brush and whiting, or burnished. The hardness of the silver varies with the power of the battery, a weak current depositing silver of very soft quality; but if the battery is too powerful, or the silver plate forming the positive electrode is very large in proportion to the article to be plated, the silver is apt to be precipitated in the form of a black powder; with due proportions between the power of the battery and the work to be accomplished, the silver deposit may be of the hardness of the rolled or hammered metal. Any desired thickness of the deposit may be given according to the time the operation is continued. A plating as thick as ordinary writing paper consumes from $1\frac{1}{4}$ to $1\frac{1}{2}$ oz. of silver to the square foot of surface. As before mentioned, the silver is more equally deposited by keeping the articles in motion as the process goes on. The silver is rendered harder also by the motion as well as by intensity of battery; and thus, though only the pure metal is deposited, it is rendered as durable as the alloy used for silver coin.—The solution employed for electro-gilding is prepared by digesting the chloride of gold, obtained by dissolving the metal in nitro-muriatic acid, with calcined magnesia. The oxide, which falls as a precipitate, is washed by boiling in nitric acid, and is then dissolved in cyanide of potassium. The solution of the double salt is used, as that of the cyanides of silver and potassium in plating. The temperature is not allowed to fall below 130° F. in gilding copper, and for gilding silver it should be still higher. The battery must be formed with the positive plate of gold, and the negative may be of iron or copper in a porous vessel containing cyanide of potassium. The same attention must be given to having the surfaces to be gilt thoroughly cleaned, except that the use

of nitric acid is dispensed with. Metallic surfaces that do not readily receive the deposit of gold, as those of iron, steel, lead, &c., may first be coated with a thin layer of copper, upon which the gold is then deposited. The solution should contain sufficient gold to deposit all that is required at once. The value of the material employed is very trifling in comparison with the effect produced. A silver thimble receives only 5 or 6 cents' worth of gold; a common sized watch case, thinly coated within and heavily without, requires only from 20 grains to a pennyweight, or about the value of a dollar; and a pencil case from 3 to 5 grains, or less than 20 cents' worth.—The applications of this new and interesting art are already wonderfully developed, and its practice gives employment to many thousands of workmen in the large plating and other electro-metallurgic establishments of our cities and manufacturing towns. The facing of printers' types with copper, now largely practised, trebles or quadruples their durability. But it is by no means probable that its most valuable uses are yet discovered. In France the possibility of applying its principle to the separation of metals from their ores, has been seriously considered by scientific and practical men; and when more economical modes of exciting the electric current are developed, it is probable that this mode of reducing some of the ores may be successfully practised. It has even been thought possible to apply a coating of copper in one sheet upon the bottom of a ship by this method, or to restore old sheathing by adding to its thickness without removing it from the vessel; and it has been proposed, as a more economical method of obtaining the electric current, to employ the magneto-electric machine, in which this power is generated by the consumption of cheap fuel in running a steam engine, instead of the more expensive zinc in the voltaic battery. But in the experiments of Messrs. Elkington and Mason, of Birmingham, England, with the command of a magnificent machine, and of steam power, the current was found to be too unsteady to admit of good work. Machines of the same construction have been introduced into New York and applied to practical operations in electro-plating.

ELECTRODE (Gr. *ηλεκτρον*, and *οδος*, a way), a term applied by Prof. Faraday to the surface, whether of air, water, metal, or other substance, by which electricity passes into or out of other media. It corresponds with the pole of the galvanic battery.—Under another derivation from *ηλεκτρον*, and *ειδος*, like, the term has also been employed to designate bodies which become electric like amber.

ELECTROLYSIS, ELECTROLYTE (Gr. *ηλεκτρον*, and *λυω*, to set free), terms which were introduced by Prof. Faraday, and applied, the one to decomposition produced by the electric current, and the other to a body susceptible of direct decomposition in this manner.

ELECTROMETER (Gr. *ηλεκτρον*, and *μετρον*, measure), **ELECTROSCOPE** (Gr. *ηλεκτρον*, and

σκοπεω, to see). These terms are often used as synonymous, though the former is properly the name of an instrument for measuring the intensity of the electrical excitement, and the latter of one for rendering it apparent by its effects. The torsion balance of Coulomb admirably combines the requirements of both instruments, but a great number have been contrived of both, and of greater pretensions and complicity, which it will not be necessary to describe. A very fine brass wire is suspended from a fixed point, and kept stretched by a small weight attached to its lower extremity. Near the weight a fine needle is attached to the wire in a horizontal position, one of the ends of which is a conductor, and the other a non-conductor of electricity. A graduated arc is arranged around the circumference of the glass vessel in which the needle is suspended. The small body, the electricity of which is to be determined, being let down the side of the vessel, causes the swinging index to diverge or be attracted, and the amount of the movement is measured by the number of degrees upon the arc passed by the index on the opposite end of the needle. An instrument has been constructed in which a force equal to $\frac{1}{1000}$ of a grain caused the needle to traverse the whole circumference, so that a movement of one degree indicated a force not greater than $\frac{1}{100000}$ of a grain. For an instrument so delicate, the suspending wire is of extreme fineness and considerable length. The principle adopted for determining the relation between the electric force and the quantities of electricity in bodies was to take two perfectly similar conducting balls, and after charging one and determining its effect upon the balance, bring it in contact with the uncharged ball. The amount of electricity is then equally divided between the two, which may be proved by testing their equal effects upon the balance. One of these may then be made to give up half its electricity to another perfectly similar uncharged ball, and so the quantity may be continually reduced in known proportions to any desired extent. An electric needle used as an electroscope, is a light bar of some non-conducting substance, supported upon a point like a magnetic needle, and bearing upon one extremity a small body charged with a known electricity. Bennett's gold leaf electroscope, which is much used, consists of two thin strips of gold leaf, fastened in the end of a metallic rod, which passes through the neck of a bell glass, and terminates above in a brass knob. These strips of gold leaf hanging in the centre of the bell glass will diverge when any body electrically excited is brought near or in contact with the brass knob. It is well to place two conducting bodies in such a position in the bell glass that each strip of gold leaf may hit against one of them, and thus discharge its electricity; for otherwise, if they come in contact with the non-conducting glass as they diverge, their tendency is to remain attached to it. The subject is particularly noticed in the preceding articles treating on electrical subjects.

ELECTROPHORUS (Gr. *ηλεκτρον*, and *φέρω*, to bear), a convenient form of an instrument for obtaining and holding small quantities of electricity for a considerable time. It consists of a flat, smooth cake of resin, made by pouring the substance when melted into a wooden mould in which it may be allowed to remain; and also of a disk, either of brass or of wood covered with tin foil, its diameter less than that of the cake; its edges should be rounded. A glass handle is inserted into the middle of the disk at right angles with its surface. The surface of the cake, as it lies upon the table, being rubbed or beaten with the skin of a cat, is soon charged with negative electricity. If the disk is then laid flat upon the cake, touched with the finger, and then taken off by the handle, it is found to be charged with positive electricity, so as to give a spark like the prime conductor of the electrical machine. By renewing the contact it is charged again, and the process may be repeated hundreds of times, the resin often retaining its electricity for many days. The positive electricity in the disk is developed by induction. If the disk is left insulated without touching the finger or other conductor to it, no electricity is developed in it, except a slight negative charge received directly from the resin.

ELECTROTYPE. See **ELECTRO-METALLURGY.**

ELECTUARIES, a name retained in the Edinburgh pharmacopœias for mixtures of medicinal substances, generally dry powders, with sugar or any sweet sirup, to render them more convenient to take. Conserves are similar preparations, the saccharine portion being intended to preserve the other ingredients mixed with them. The word confection is now in use in the pharmacopœias of the United States, London, and Dublin, to include both.

ELEMENT, CHEMICAL. In the present state of science this term admits of no very precise definition. In general, the word element is applied to any substance which has as yet never been decomposed into constituents or transmuted into any other substance, and which differs in some essential property from every other known body. Several elements indeed occur under two or more allotropic conditions, in which states they exhibit different properties. These modifications are however mutually convertible into each other, and are regarded as mere varieties of one and the same substance. As now used, the term element does not possess in any degree the absolute signification at one time attached to it by the ancients, none of the elements now admitted being regarded as true primary principles of matter. It is indeed not impossible that some of them may belong to this class; but of this nothing is known. Provisionally, all substances which have hitherto resisted every method of analysis that has been applied to them—all, in short, which cannot be proved to be compound—are called elements. As may readily be conceived, the number of these bodies is constantly changing with the advance of science. At present 61 such are ad-

mitted. Although this number is very small in comparison with the almost infinite variety of material substances which occur in nature, or are produced artificially by man, it will doubtless eventually be greatly lessened; all analogy teaching that the really essential elements of matter must be very few. Thus far, however, the number of elements has been continually, though slowly, increasing through the discovery of new substances. The latter have occurred in most cases only in extremely minute quantities, and in but few localities; some of them have hardly been seen by any one except their discoverer. The properties of many have not as yet been thoroughly studied. Such are viewed with suspicion and distrust by chemists, and, until authenticated, merely tolerated on the list of elements. The great mass of the matter of which the world is composed consists of about 80 elements, the remaining 31 being of comparatively slight importance. The term simple or undecomposable (better undecomposed) substance is often used synonymously with element. In popular language, fire, air, earth, and water are sometimes called elements. The last 3 are, however, compounds, while the former is an appearance, occasioned by the development of light and heat which attends chemical combination, &c.—For a complete catalogue of the elements, see **EQUIVALENT.**

ELEMI, a resinous exudation from a number of trees in different parts of the world. Coming from so many sources, the substance known in common is by no means of uniform character, and the trees which afford the gum are very little understood. That from Holland is supposed to be from the Dutch East India possessions, and the product of the *canarium balsamiferum* of Ceylon. The Manila article is believed to be the product of the *canarium commune*; that of *C. album* or *arbolabrea* is used in the Philippine islands for pitching boats and vessels. The Brazilian elemi is from the *icica icicariba*; the *icica* is a genus separated from *amyris*, to which the elemi is commonly referred. The Mexican is said by Dr. Royle to be from a species of the *elaphrium*, which he names *elemiferum*. The resin is imported in various shapes, and in different colors and degrees of consistency. It was formerly much employed in plasters and ointments, but is more used in Europe than in this country. Hatters make use of it, and it is in some demand for varnishes by coach painters. It is one of the ingredients of pastilles burned as incense. It has been resolved into two resins, one amorphous and one crystallizable, for the latter of which the name elemine has been proposed by its discoverer, M. Baup.

ELEONORA OF ESTE, an Italian princess, whose name is associated with the love and madness of Torquato Tasso, born June 19, 1537, died Feb. 10, 1581. She resided in Ferrara at the brilliant court of her brother, Alfonso II., of which she and her sister Lucrezia were the most accomplished ornaments. Tasso seems to

have conceived an ardent passion for Eleonora, and to have addressed to her some of his most fervent effusions, to the discovery of which the persecutions to which he was subjected by Alfonso were in part ascribed. But the evidence on the subject is conflicting. There were several other ladies of the name of Eleonora whom Tasso celebrated; as, for instance, Eleonora San Vitale, the beautiful countess of Scandia, in whose praise he wrote charming verses. However, most biographers agree in pointing to the princess Eleonora as the lady of his special adoration. How far the princess reciprocated his affection is not clearly established, and the presumption is that she gave him only friendship and poetical sympathy in return for his love. She was never married.

ELEONORA OF TOLEDO, daughter of Peter of Toledo, viceroy of Naples, born in 1526, was married in 1543 to Cosmo de' Medici, afterward grand duke of Tuscany, fought with great bravery against her husband's enemies, captured the chief of them (Filippo Strozzi), afterward accompanied Cosmo in the war between the emperor Charles V. and Francis I. of France, and was actively engaged in the taking of Sienna. In the latter part of her life she was distinguished for her judicious patronage of letters, the fine arts, and works of charity.

ELEONORA TELLEZ, a beautiful Portuguese woman, born in 1330, died in 1405, the daughter of a poor nobleman, was married in 1346 to a gentleman of fortune, but of less ancient descent, and much her superior in years. He brought her to the court of Lisbon, where Ferdinand I. fell in love with her. She declined becoming his mistress, but became his wife, after having been legally divorced from her husband. But her heart was as little interested in her second as it had been in her first marriage. She fell in love with a young Castilian nobleman, Don Juan d'Andeiro. Her preference for him and her tyrannical disposition produced great discontent and led to her overthrow. After the death of the king, her favorite was assassinated by the king's brother, the infante Don John (Dec. 6, 1383), who usurped the government. Eleonora besought the assistance of John of Castile, who had married Beatrix, the only child she had borne to Ferdinand. John caused her to be placed in a convent in Spain, where she died.

ELEPHANT (*elephas*, Linn.), the only existing representative of the proboscidian pachyderms; the mammoth or fossil elephant, and its congener, the mastodon, having lived in the preceding geological epoch. The elephant, the largest and heaviest of terrestrial animals, has from time immemorial been celebrated for his intelligence and sagacity, for the services he has rendered to man in eastern lands, for his imposing appearance, for his immense strength guided by gentleness and docility, and for the astonishing feats he is able to perform by means of his trunk. Since the time of Cuvier the anatomy of the elephant has been thoroughly studied. The skull is remarkable for its vertical elevation,

giving to the head the well-known aspect of sagacity; this, though far superior to that of the other pachyderms, has doubtless been overrated from the peculiar cranial formation in this animal. The great elevation of the frontal region does not arise from any increase of the cranial cavity or corresponding development of brain, but depends on the great separation of the tables of the skull, and the excessive enlargement of the frontal sinuses, affording ample space for the origin of the muscles of the trunk; the upper jaw has a similar structure for the accommodation of the enormous tusks; in both cases strength and solidity are obtained without too much weight. The nearly perpendicular facial line of the elephant, then, depends on the size of the frontal sinuses, the shortness of the bones of the nose, and the vertical position of the maxillary and intermaxillary bones; and the cranial cavity occupies but a small part of the head at its posterior central portion. The occipital bone forms the posterior wall of the skull, and advances also on to its upper surface; the parietals are early consolidated to it, to each other, and to the temporals, forming a solid box; the ethmoid is large, and the extent and surface of the cribriform plate indicate a delicate organ of smell; the sphenoid is very flat internally, but its cells are enormously developed, encroaching largely upon the base of the skull. The teeth consist of 2 long curved tusks, one in each intermaxillary bone, and of large and compound molars in each jaw. The permanent tusks, which are monstrous incisor teeth, are preceded by 2 small deciduous ones, which make their appearance between the 5th and 7th months, rarely exceed 2 inches in length and $\frac{1}{4}$ of an inch in diameter, and are shed before the 2d year, their roots being considerably absorbed; about 2 months after the milk teeth are shed, the permanent tusks, which are situated to the inner side of and behind the former, pierce the gum when about an inch long, and grow from the base during the whole life of the animal. The molar teeth are remarkable for their size and the complexity of their structure; there is not more than one wholly, or two partially, in use on each side in each jaw at one time; they are constantly in progress of destruction and formation, succeeding each other horizontally, instead of vertically as in other mammals; according to Owen, the molars are successively brought forward until each jaw has had on each side 6, or 24 in all. For the minute details of the structure and development of the molars, the reader is referred to the *Ossemens fossiles* of Cuvier, and to the "Odontography" of Owen. It will be enough to say here that each tooth is composed of a number of transverse vertical plates of dentine or ivory, enveloped in enamel, and united together by the cement of *crusta petrosa*; only a small portion of the crown appears above the gum. This gradual progress of the teeth from behind forward explains how the elephant has always a grinding surface ready to bear the great pressure to which his teeth

are always subjected; the constant wear of the grinding surface keeps it in order for mastication; the manner in which the enamel is arranged on this surface, after the ivory is worn down, enables the anatomist to refer a tooth either to the Asiatic or African elephant. From the oblique position of the molars in the jaws, the anterior portion pierces the gum first, and may be quite worn while the middle and posterior portions are slightly or not at all used, so that these teeth diminish in length at the same time that their depth is worn away; as the anterior grinding surface becomes useless, the root is removed by absorption, enabling the tooth to be pushed forward by that behind. The tusks are formed of ivory and enamel, the former making the central and by far the largest portion; the tusks exist in both sexes, but are smaller in the females than in the males; they sometimes measure 9 feet in length, and weigh over 200 lbs. the pair; this great weight is kept in place only by the tight embrace of the socket and surrounding parts, explaining the abnormal direction of the tusks produced either by sudden and violent or by gentle and long continued pressure. The lower jaw is massive, and prolonged in front, where the extensible lower lip is elongated into a triangular deeply concave organ for receiving the extremity of the trunk. The spine consists of 7 cervical vertebræ, 20 dorsal, 3 lumbar, 5 sacral, and from 24 to 26 caudals; the number of ribs is 19, and in some specimens 20, of which 5 or 6 are true. The thoracic cavity is very large, the ribs being continued back nearly to the pelvis, of great size and width; the sternum is long, compressed laterally, and somewhat prolonged in front. The limbs being designed more for strength and solidity than speed, their bones are thick and large; the shoulder blade is wide, its posterior margin much the shortest; and the spine, beside the acromial process, has a broad, sickle-shaped prominence extending downward and backward; there is no clavicle, as the approximation of the limbs toward the centre of gravity is necessary to support the weight of the body. The humerus is short and massive, the upper extremity having a flat articular surface with large protuberances for the insertion of the muscles of the shoulders, a strongly ridged shaft, and a pulley-like lower surface for the forearm, admitting only of flexion and extension; the external condyle is very extensive upward. The radius and ulna are permanently pronated, and both enter into the formation of the elbow and wrist joints; the 8 bones of the wrist are arranged in 2 rows, and the 5 metacarpals are short and robust, 5 fingers being attached to them; the fingers, however, are concealed by the thick and overhanging skin, with the exception of the ends. The pelvic bones are large, to accommodate the powerful muscles to which they give origins; the ilia are broad, rounded anteriorly and concave toward the abdomen; the femur is simple in shape, comparatively smooth, resembling considerably that of man;

this resemblance is continued in the leg and tarsus; the os calcis is very large and prominent; the metatarsus consists of 5 bones, the external one being imperfectly developed; the toes are also 5, each consisting of 3 bones, except the outer, which has one, all encased in the thick skin, the division being indicated only by the projecting extremities. The bones of the elephant may be easily distinguished from those of other quadrupeds; they resemble, except in size, the bones of man, particularly the cervical and dorsal vertebræ, the shoulder blade and pelvis, the femur, tarsus, and the bones of the metacarpus and metatarsus; so that it is not surprising that even anatomists, ignorant of the elephant's skeleton, should have mistaken their recent and fossil bones for the remains of gigantic human beings. The food of the elephant is entirely vegetable, and must be immense in quantity, and the digestive apparatus is accordingly largely developed; the stomach is simple, of a lengthened and narrow form, its cardiac extremity being prolonged into a pouch of considerable size, its internal membrane divided into thick folds and transverse wrinkles, and its muscular coat very thick; the small intestines are voluminous, and the large of enormous size; in a moderate-sized animal the intestinal canal was 60 feet long, the small intestines being 38 feet, the cæcum $1\frac{1}{2}$, and the large $20\frac{1}{2}$ feet; the circumference of the 1st being 2 feet, of the 2d 5 feet, and of the last (colon) 6 feet. The gall bladder is situated between the coats of the duodenum, and is divided by transverse partitions into 4 compartments; the spleen is 4 feet long. The heart resembles that of the rodents in having 8 venæ cavæ opening into the right auricle, 2 above and one below, and the Eustachian valve is furnished with a rudimentary superior division. The brain is small in proportion to the size of the animal; in one $7\frac{1}{2}$ feet high the whole organ weighed but 9 lbs., and in another 9 feet high the internal capacity of the cranium was only 854 inches, being less than 8 times the weight of the human brain, and less than 4 times the capacity of the Caucasian skull; the convolutions are well marked, and the cerebellum is proportionately very large; the 5th pair of nerves, which supply the trunk, are enormously developed. The trunk of the elephant is an elongated nose, but is chiefly an organ of touch, though capable of being used for smelling; it forms a conical mass, 4 or 5 feet long, gradually tapering to the end, which is provided with a thumb-like appendage, endowed with a most delicate sense of touch, and capable of picking up a needle; it contains a double tube, strengthened by membranes, extending up as far as the bony nostrils, just before which they form a sudden curve; the true nasal passages are provided with a valve by which the cavity of the trunk may be cut off from the nose, a provision rendered necessary when the animal takes fluid into the former. The great bulk of this organ is made up of transverse and longitudinal muscles so arranged that the trunk may

be elongated, shortened, raised, and bent in any desired direction, with all the precision of the human hand. Though the trunk is capable of performing the most delicate operations, it is also an organ of great strength and a weapon of the most formidable character; with it the animal tears the branches from trees in its search for food, performs the heaviest tasks for his human owner and defends himself from his smaller enemies; with it he introduces food and drink into his mouth, which, from the shortness of his neck, he cannot bring to the ground; by inspiring through the trunk he fills it with water, which he discharges into his mouth or in refreshing showers over his back. So important is this organ that the animal's first act when in danger is to raise it above his head; when hunting the tiger or other wild animal, he carries it high in the air; any wound of it seems to render him helpless; in ordinary cases he rarely uses it to strike an object. When crossing deep rivers the body is deeply immersed, and respiration can be carried on with only the tip of the trunk above water. The sense of smell is acute, though not resident in the trunk proper, as is indicated by the extent of the frontal and maxillary sinuses communicating with the nose; the sphenoidal sinuses are also of unusual dimensions. The sense of hearing is also acute, as it should be for an animal living in thick woods and jungles, in which vision can hardly detect the approach of an enemy; the ear communicates with extensive bony cells, and the external auricle is large to collect the sounds and convey them to the tympanum. The eye is small, but is well protected by thick lids and a nictitating membrane. The muscular system is of immense strength; and the ligamentum nuchæ, which supports the heavy head, is of uncommon size and firmness.—Elephants inhabit the tropical forests of Asia and Africa, living in troops; though often destructive to trees, and especially to saccharine plants, they are quiet and inoffensive unless attacked by man or other animals; they prefer well-watered regions, where a large herd may frequently be seen guided by some old male, keeping in the shade during midday and feeding at morning and evening; easily alarmed, they retire to the woods at the approach of man, but if pursued will turn and attack him with the greatest fury. Only 2 species are described, the Asiatic and the African elephant. The Asiatic elephant (*elephas Indicus*, Cuv.), extensively distributed over S. India and the E. Asiatic islands, has an oblong head, concave forehead, and the crowns of the molars presenting transverse undulating ridges; the ears are small compared with those of the African species. The skin is hard and thick, wrinkled about the legs, neck, and breast; the general color is a brownish gray, mottled sometimes with lighter spots; pure white albinos are very rarely seen; the hairs are few and rigid, most abundant on the head; the feet have 5 toes, the nails of which are seen beyond the cutaneous envelope.

The usual height is from 7 to 10 feet, that of the females a foot or two less; specimens are on record considerably larger than this, some having a length of 15 feet and a height of over 12. The period of gestation is about 20½ months; the new-born animal is 8 feet high, with all its senses perfect; sucking is performed by the mouth, the trunk being turned back, and is continued for a period of nearly 2 years. The young grow rapidly, being 4 feet high in the 2d year, and are said to be suckled indiscriminately by any female in the herd; they attain maturity at about the age of 30 years, and live certainly for 150 years, and probably for 200. The weight of a full-grown elephant is from 3 to 5 tons; one kept in London for many years, between 10 and 11 feet high, consumed daily 3 trusses of hay and about 200 lbs. of carrots and fresh vegetables, drinking from 60 to 80 gallons of water; this fine specimen cost, on his arrival in England in 1810, 900 guineas; he performed in pantomimes at the theatres for several years; he was subject to periodical fits of rage, during one of which it was deemed necessary to kill him, which was done by the discharge into his body of about 150 rifle balls, and by several severe sword and lance thrusts. Though the elephant will breed in captivity, the supply for domestic and warlike purposes must be kept up by hunting the wild animals and reducing them to servitude; the favorite way in India is to capture the wild by the aid of tame animals, especially females; these display as much treachery, ingenuity, perseverance, and courage, as did ever human seducer to compass the destruction of a victim. Following in the track of the male wild animals, the wily females move gradually toward them, grazing with the same complacency and indifference as if they were inhabitants of the forest; while the females are cajoling a male, the hunters cautiously approach and fasten his legs by ropes to trees, the former distracting the attention of the intended captive, and even assisting in binding the cords; the females then leave him, when he has discovered his condition, to vent his useless rage to his own exhaustion; further reduced by hunger and thirst, he will soon allow himself to be led by his treacherous companions to stations appointed for the training of elephants, where, after a few months' discipline, he becomes quite docile and contented. There are various other modes of taking elephants by female decoys, by stratagem, and by driving. Elephants, both Asiatic and African, frequently figure in the history of the wars of the Greeks and Romans. Darius III. had a small number of them in his war against Alexander; Porus of India brought a large number into the field against the same conqueror. Seleucus had hundreds of them in his army at the great battle of Ipsus. Pyrrhus of Epirus, Hannibal, and Antiochus the Great fought with elephants against the Romans, who themselves soon made use of them in their campaigns, and also exhibited them at their public shows, triumphs, and combats of

wild animals in the theatres. In the ancient Indian empires, elephants formed a necessary appendage to the royal retinue; they were used for show, for warlike purposes, and for carrying burdens. In the East at the present time elephants are employed for transporting baggage, dragging artillery over difficult places, and otherwise in connection with army movements, but without entering into the actual manoeuvres of battle; they exercise their strength and sagacity in lifting, dragging, and pushing with their leather-protected foreheads. When the elephant gets under full headway, his speed is considerable, and his momentum overcomes all ordinary obstacles; though able to carry an immense weight on a level surface, he is liable to totter and fall backward when forced up considerable elevations; a strong animal can travel 50 miles a day, with a burden weighing a ton. The anecdotes illustrating the docility, affection, sagacity, irritability, capriciousness, and revengeful spirit of the elephant, are innumerable, and may be found in various well-known books on natural history. The natural enemies of the elephant, beside man, are the tiger and the rhinoceros, and the nasal horn of the latter often proves a more formidable weapon than the trunk and tusks of the elephant; the sight of even a dead tiger is enough to excite most elephants into a transport of fury.—The African elephant (*E. Africanus*, Cuv.), genus *Loxodonta* (F. Cuv.), has a more rounded head, a rather convex forehead, enormously long ears, and cheek teeth with lozenge-shaped divisions of the crown; the generic name of F. Cuvier was founded on the last characteristic. It inhabits Africa from Caffraria to the Niger, living in similar localities and with the same manners as the other species. The males attain a height of over 12 feet, but decrease in size north of 20° S. latitude; the tusks, however, are larger, according to Livingstone, as you approach the equator; the females are smaller than the males. Under the tropics, animals as well as men decrease in size, though food there is most abundant; such climates seem unfavorable to full animal development. The natives estimate the height of this species by doubling the circumference of the impression made by the fore foot; this is tolerably accurate for adult animals. In the most favorable localities the African elephant is considerably larger than the Asiatic; but toward the equator the female African is about as large as the Asiatic male. The ear of the African species is sufficient to distinguish it, being often more than 5 feet long and 4 feet wide, 8 times as large as that of the other species; it descends upon the legs, and is frequently used as a sledge at the cape of Good Hope. From the ancient coins it is evident that this species was known by the old naturalists, and it has been justly said that Aristotle knew it better than did Buffon. It seems to be a dainty feeder, selecting the sweetest fruits and vegetable matters containing sugar, mucilage, and gum; there is a dwarf-

ish evergreen, the "speck boom," which forms very dense jungles in Caffraria, utterly useless on account of its pithy branches even for fuel; this is a favorite food of elephants, which 25 years ago frequented this region in large herds, whose paths are still discernible on the hillsides, and whose bones are seen bleaching in all directions. From this selection of food they are not so injurious to the vegetation of a district as would be supposed, quality being more requisite than quantity. Most of the native tribes hunt them more for their flesh than their ivory, the latter, until the advent of Europeans, being of little value to them except for rings and ornaments; the flesh is much relished as food, and the internal fat is highly prized for domestic and medicinal purposes. They hunted them with light javelins of their own making, overpowering them by numbers. A few white hunters like Gordon Cumming would soon exterminate this noble animal. This species is wilder and fiercer than the Asiatic elephant, defending its young with great courage, and furiously attacking the hunter; though not domesticated in modern times, it probably might be as easily as the other species, were the same pains taken to tame and train it; it can hardly be doubted that the elephants used by the Carthaginians in their wars with the Romans were of African origin. The length of the male tusks is from 6 to 8 feet, and their weight from 60 to 100 lbs. each; Cumming mentions a single one in his possession 10½ feet long, and weighing 173 lbs.; the price which they bring in the English market is from \$120 to \$160 per 112 lbs. according to quality. Such is the terror which these animals have acquired from the persecutions of man, that a child will put a herd to flight; they are very difficult to hunt, from their hiding themselves in the most remote and inaccessible forests, going often 20 miles by night to water. When at ease they sleep on their sides, but when liable to be disturbed they sleep standing; their gait, when natural, is bold, free, light, and graceful. Cumming gives an interesting description ("Hunter's Life in South Africa," vol. i., p. 304) of the manner in which the Bechuanas cook the feet and trunk of the elephant in hot earth and sand. In his experience from 5 to 80 rifle shots were necessary to kill an elephant, and the best place to direct them is just behind the shoulder; it is useless to aim at the front of the head, as the chances of a ball penetrating the brain from this direction are very small. The destruction of these noble animals for the purpose of supplying the world with ivory must be immense; whenever the regions inhabited by them shall be occupied by agricultural tribes, the animals must retire and finally be exterminated by the inability to obtain sufficient food; when it is remembered what a quantity of vegetable food herds of elephants require, it must be evident that man and such large herbivora cannot coexist in the same districts.—Many species of fossil elephants are described from the drift of Europe and Asia; the best known of these, the *E. pri-*

migenius (Cuv.), will be treated in the article MAMMOTH, which is the common name; their remains have been abundantly found in Siberia, and fossil ivory from this source has been an important object of trade. The fossil elephants of Europe resemble most the Asiatic species, but they were more bulky, with larger tusks, narrower teeth, and with the skin covered with hair and wool to enable them to dwell in climates colder than any in which these animals are now found, though not in a climate so rigorous as that of Siberia at the present time, which would be unable to furnish the necessary vegetable food. Fossil species resembling the African, and others with mastodon-like teeth, have been found in the Himalaya mountains by Cautley and Falconer. The fossil elephant of North America is said by Prof. H. D. Rogers ("Proceedings of the Boston Society of Natural History," vol. v., p. 22) to occur above the drift, in the superficial deposits of a distinctly later age; it must, therefore, have been contemporary with the *mastodon giganteus*; indeed their bones and teeth have been found side by side in the marshy alluvium of Big Bone Lick, and the two animals must have been exterminated together; from this one of two conclusions must be derived: either the drifts are not of the same epochs, or else the fossil elephants of the two regions must be different species.

ELEPHANTA, or GARAPORI, a small island of British India, on the E. side of Bombay harbor, about 5 m. from the mainland; lat. $18^{\circ}57'$ N., long. 73° E.; circumference about 5 m. It consists of 2 hills with a valley between them, much overgrown with wood, but diversified with some rice fields and pastures. The inhabitants, about 100 in number, are engaged in rearing sheep and poultry for the Bombay market. The usual landing place is on the S. coast, about 250 yards from which, rudely cut from an isolated black rock, was the figure of an elephant, 13 feet long, now fallen to decay, from which the European name for the island is derived. Further inland, about half way up the N. side of a hill, is a remarkable cave temple of unknown antiquity, which has long been deserted by its priests, and is now frequented only by married women praying for fecundity. The spacious entrance, 60 feet wide and 18 feet high, is supported by 2 massive pillars and 2 pilasters, being thus divided into 3 passage ways. The interior breadth of the cavern is 123 feet, and its length, presenting a seemingly endless vista of huge columns cut from the living rock, some of them broken by the Portuguese, who formerly possessed the island, is about 180 feet. The roof is generally flat, though not a perfect plane. The sides are excavated into compartments, all filled with mythological sculptures. Opposite to the main entrance there is a bust supposed to represent the Hindoo trinity, viz.: Brahmā, Vishnu, and Siva. The heads are 6 feet long and well cut. The head dresses are curiously ornamented, and among other symbols a human skull and a young infant are represented on that of

Siva, who also holds in his hand a cobra de capello. Several other figures of Siva, one of the 4-faced Brahma, and one of the double deity, half male, half female, called Viraj, formed by the union of Siva with Parvati, are also to be seen. There are 2 smaller excavations on the E. and W. slopes of the hill, similar to the great temple, and filled with representations of Hindoo deities. But what is most remarkable is, that although most of the subjects of these sculptures are evidently Brahminical, and the temples were probably dedicated to Siva, there is at least one figure which appears to be that of Buddha. No record of the origin of the shrines can be found. The general opinion of Europeans who have examined them is that they date from a period subsequent to the birth of Christ, perhaps as late as the 9th or 10th century.

ELEPHANTIASIS. Under this common name two entirely different diseases are comprehended: *E. Arabum*, elephant leg, or Barbados leg; and *E. Gracorum*, elephant skin, or tubercular elephantiasis. I. *Elephantiasis Arabum* was described by Rhazes in the 9th century; it prevails extensively in Barbados, whence the name Barbados leg; it is common in Demerara, Cayenne, and Brazil, in the S. W. part of the island of Ceylon, and on the Malabar coast in India; it is sometimes found in Castile and the Asturias in Spain, and occasional sporadic cases are met with throughout Europe and America. Notwithstanding its name, the disease is not confined to the leg, but may attack almost any part of the body. The attack is ushered in by marked rigor, headache, pain in the back and limbs, followed by heat of the skin, alternating with profuse perspiration, and attended with burning thirst; at the same time some part of the body becomes red and swollen, hot and painful, particularly along the tract of the lymphatic vessels. In a few days the symptoms, both general and local, subside, with the exception that the affected part remains more or less swollen. At irregular intervals similar paroxysms recur, the affected part being each time left more swollen and indurated; as the enlargement increases, the skin often becomes rough, covered with scales, and fissured. The disease is usually confined to one part of the body, though occasionally both legs are affected. The affected parts often attain an enormous size. The causes of Barbados leg are not understood; its occurrence in particular districts shows that local causes have something to do with its production. In the West Indies the negroes, and in Ceylon the native race, are affected much more frequently than the whites; and of the whites, the creoles, those born in the country, are more liable than recent immigrants. In the treatment of the disease in the earlier stages, emollient applications, the warm bath, and bloodletting have been advised. Some physicians think benefit has been derived from the exhibition of mercury. When the disease has already made considerable progress, rest in a

position which favors the return of the blood from the limb, and compression by means of proper bandaging, are the means most to be relied upon. II. *Elephantiasis Græcorum*, tubercular elephantiasis, appears to have been the disease which during the middle ages was known as leprosy; it is most frequently met with in the West India islands, and in other tropical regions, while it also prevails extensively in certain parts of Norway, where it is known as *spédalsked*. The disease ordinarily commences by the appearance of dusky shining spots upon the skin, slightly swollen, and more or less insensible. After a variable period, which may extend to months, and even years, these spots are succeeded by tubercles or small tumors, soft, reddish, or livid in color, and varying in size from a pea to an English walnut. These tubercles developed upon the face deform it excessively, giving it often a fancied resemblance to the head of the lion, whence one of the names by which the disease is known (*leontiasis*) is derived. As the disease advances, the tubercles become inflamed and ulcerated; the ulcers exude a sanious fluid, and this concretes into thick crusts; the bones become softened and altered in form. In the progress of the disease the gastro-intestinal mucous membrane becomes involved, and tubercles make their appearance in the pharynx; the sense of smell is lost, sight is weakened, and the touch blunted. In this wretched condition the patient may continue to exist a long time, unless cut off, as is commonly the case, by some intercurrent disease. In a second form of the disease, *E. anæsthetica*, patches of an irregular shape, sometimes slightly elevated above the surface, appear upon the extremities, of a tawny color; in whites they are lighter than the rest of the surface; in the negro they are dry, shining, rough, denuded of hair, and insensible. The hands and feet, and then the extremities, generally become swollen, stiff, and numb; ulcers form on the metacarpal and metatarsal articulations; these enlarge, penetrate the joint, and finally amputate the toes and fingers. As the disease advances, the pulse becomes slow and the bowels constipated; sometimes it is complicated with the tubercles of the other variety; in other cases the lobes of the ears, the wings of the nose, and the lips, become thick, hard, swollen, and ulcerated. The patient is listless, and his intellect enfeebled, and in this condition he may live many years. The causes of tubercular elephantiasis are unknown; it appears to be hereditary; but the once prevalent opinion of its contagiousness is not found to agree with recent observations. Of its proper treatment little is known, and when once fully developed it has hitherto seemed incurable.

ELEPHANTINÉ, or ELEPHANTINA (Arab. *Jezeeret-el-Sag*, "islet of flowers," or *Jeziret-el-Asswan*), an island of the upper Nile, about 1 mile long and $\frac{1}{2}$ m. broad, at the foot of the little cataracts, opposite Asswan, the ancient Syene. It is formed of granite covered with a

fertile soil. It contains several ancient ruins; among others, the Nilometer mentioned by Strabo, whose upper part was destroyed in 1822, several dilapidated temples, and a gateway, as well as numerous fragments of pottery with Greek inscriptions. In antiquity Elephantiné or Elephantis was renowned for its fertility. Herodotus regards it as forming the boundary between Egypt and Ethiopia; but afterward Phyle was regarded as the southern landmark of Egypt. Elephantiné was strongly garrisoned by the Persians as well as Romans for the defence of this province.

ELEUSIS, in modern times Lessina or Lep-sina, a fortified town in Attica, on the bay of Salamis. According to ancient mythology, it was founded by Eleusis, a son of Hermes. At an early period it was conquered by the Athenians and became one of the most populous cities of Attica. Its principal importance was derived from its being the seat of the celebrated Eleusinian mysteries. These mysteries formed a peculiar religious festival celebrated in honor of the goddess Demeter or Ceres, the patroness of agriculture, and the representative of the procreative power of nature. Originally these celebrations appear to have been something like modern thanksgiving festivals, but afterward a symbolic meaning was attached to them, and they became the vehicle of a secret science, conducive, as was believed, to eternal bliss. They consisted in dramatic representations of the myth of Ceres and the rape of Proserpine, her daughter, by Pluto, and would seem to have been intended to propagate the belief in the immortality of the soul, and to give an ideal meaning to the coarse fancies of the popular religion. The great Eleusinian mysteries were celebrated at Athens and Eleusis in the latter half of September and the 1st of October; they lasted 9 days; the lesser took place at Agræ on the Ilissus during the spring. Except to murderers, barbarians, slaves, and afterward Epicureans and Christians, the admission to the public performances and religious exercises was free for all; but in the secret allegorical representations none but the initiated were permitted to participate, and they were bound by solemn oaths never to reveal what they had seen or heard. The unity of God and the immortality of the soul are supposed to have been the secret doctrine of the mysteries. In 1858 a Greek schoolmaster, named Vlastos, discovered at the village of Hagi-Constantios an inscription upon an old marble slab, containing rules and regulations for the celebration of the Eleusinian mysteries, but nothing was learned from them about their allegorical meaning.—See Uwaroff, *Essai sur les mystères d'Éleusis* (3d ed., Paris, 1816), and Preller, *Demeter und Persephone* (Hamburg, 1887).

ELEUTHERA, or ALABASTER ISLAND, one of the largest of the Bahamas, and the principal fruit-growing island of the group, in lat. 24° 38' N., long. 76° 9' W.; area about 100 sq. m.; pop. in 1851, 8,400. It is of irregular shape, long

and narrow. The soil is fertile and the climate agreeable. The chief settlements are at Governor's Harbor, the Cove, Wreck Sound, and the Current.

ELEUTHERIA (Gr. *ελευθερια*, freedom), among the ancient Greeks, a festival commemorative of deliverance from the armies of Xerxes. It was instituted after the battle of Plataea (479 B. C.), and celebrated annually at that place in the month Maimacterion, nearly corresponding to our September. At the dawn of day a procession marched through the town, at the head of which trumpeters blew the signal for battle. At midday a chariot was driven toward the altar crowned with myrtle and various garlands, and leading behind it a black bull. In front of the altar the archon of Plataea immolated the bull to Jupiter and Mercury, eulogized the heroes who had fallen at Plataea, and sprinkled the ground with wine. Every 5th year these solemnities were attended by contests, chaplets being the reward of the victors.

ELGIN, a city of Kane co., Ill., on both banks of Fox river, 42 m. N. W. from Chicago; pop. in 1850, 2,359; in 1858, about 4,000. It is a prosperous trading place, being situated at the junction of the Fox river valley and the Galena and Chicago union railroads. It has 2 weekly newspaper offices, a bank, 3 hotels, a grist mill, a distillery, a carriage factory, 2 manufactories of agricultural implements, and several schools and academics. It was settled in 1835.

ELGIN, a S. W. county of Canada West, on the N. shore of Lake Erie, traversed by Otter creek, and bordered by the Thames river; area, about 700 sq. m.; pop. in 1852, 25,418.

ELGIN, formerly **MORAY**, a maritime co. in the N. of Scotland, bounded N. by Moray frith, extending 40 m. from N. to S., and having a breadth of from 8 to 23 m.; area, 840 sq. m.; pop. in 1851, 38,959. It has a coast line of about 30 m., on which are a few small harbors. With the exception of some broken masses of rock, the surface in this quarter is nearly level, but inland it rises into hills, interspersed with fertile valleys, and diversified by lakes. The Spey, Lossie, and Findhorn, the first and last of which contain salmon, are the chief rivers. Slate and freestone are the only valuable minerals. The climate is mild and dry; the soil of the lowlands is generally fertile, and the hills furnish pasturage for black-faced sheep, cattle, and horses. The staple production is wheat, but oats, potatoes, and turnips are also grown extensively. Less than $\frac{1}{2}$ of the land is cultivated, and there are still large unenclosed tracts. Corn, whiskey, fish, and timber are the most important exports. The county is traversed by a number of good roads, but has no canals and no railways. Chief towns, Elgin, Forres, Fochabers, and Burghead. —**ELGIN**, a royal parliamentary and municipal burgh and city, capital of the above county, on the S. bank of the Lossie; pop. of municipal burgh in 1851, 6,337. It is surpassed by few cities of Scotland in the number and interest of its ancient monuments. In former times it

was a bishop's see; its cathedral was founded in 1224, and was burned in June, 1890, by Alexander Stuart, commonly called the wolf of Badenoch. Bishop Barr soon after erected in its stead a cruciform church with 3 towers. About the year 1568 the privy council ordered the lead to be stripped from the roof and sold to maintain the soldiers of the regent Murray. The noble structure has ever since been falling piecemeal to destruction. The great central tower and spire, 198 feet high, fell in 1711. The chapter house, a beautiful piece of architecture, in the shape of an octagon, with a groined roof, supported by a handsome column in the centre, and elaborately ornamented, is still entire. As late as the beginning of the 19th century Elgin bore much of the antiquated look of an old ecclesiastical town, but it is now greatly changed. New houses and streets have taken the place of the old; assembly rooms have been fitted up; a neat modern church has been built; and the streets are well swept, drained, and lighted with gas. Gray's hospital or infirmary, an institution endowed with £26,000, occupies an elevated site in the western part of the city. An orphan asylum here was endowed with £70,000. In connection with Banff, Cullen, Inverary, Kintore, and Peterhead, Elgin returns one member to the house of commons.

ELGIN AND KINCARDINE, **THOMAS BRUCE**, 7th earl of, a British nobleman, born July 20, 1766, died in Paris, Nov. 14, 1841. He passed some time at the university of St. Andrew's, studied law in Paris, and having pursued military studies in Germany, entered the army and rose to the rank of general. His time, however, was mostly passed in diplomatic employments. After having been intrusted with missions to Brussels and Berlin, in 1799 he was sent as envoy extraordinary to Constantinople, when the idea occurred to him of rescuing from time and the Turks and removing to England the celebrated sculptures which are now in the British museum, and bear his name. On his way home he passed into France, where Napoleon detained him as a hostage on the rupture of the peace of Amiens. He was released in 1806, and passed the rest of his life without public employment. He was a Scotch representative peer for 50 years. In 1810 Lord Elgin published in defence of his conduct a 4to volume, entitled "Memorandum on the subject of the Earl of Elgin's Pursuits in Greece." —**JAMES BRUCE**, 8th earl, son of the preceding, a British statesman, born July 20, 1811. His studies were begun at Eton, and completed at Christchurch, Oxford, where he was graduated in 1833. He was afterward elected fellow of Merton college. He commenced public life as one of the members of parliament for Southampton in 1841, but, ere the year was out, succeeded to the title and estates of his father. In the succeeding year he was appointed governor of Jamaica, and was promoted in 1846 to the more responsible and lucrative post of governor-general of Canada. Under his administration Can-

ada passed from the ferment of recent insurrection into a state of tranquillity. Through his energy and diplomatic skill the negotiation of the reciprocity treaty with the United States was brought to a successful conclusion in 1854, after which he resigned the office of governor of Canada, returned to England, and received the appointment of lord lieutenant of Fifeshire. In the spring of 1857 he was appointed minister plenipotentiary to Peking, immediately proceeded to the East, was present at the taking of Canton, and, in conjunction with the French, succeeded by vigorous measures in reducing the Chinese to terms. After signing a treaty with the Chinese commissioners at Tientsin, July 26, 1858, the conditions of which were highly favorable to the British, he sailed for Japan, boldly entered the harbor of Jeddo, from which foreigners had always been rigidly excluded, obtained important commercial privileges for his countrymen, concluded a treaty with the Japanese, Aug. 26, and in May, 1859, returned to England. Lord Elgin has been twice married, his second wife being the daughter of the earl of Durham, former governor-general of Canada.

ELGIN MARBLES, a collection of ancient sculptures, chiefly taken from the Parthenon at Athens, now deposited in the British museum. They derive their name from the earl of Elgin, who, while British ambassador at Constantinople in 1799-1802, procured the permission of the Porte to take away from the ruins of ancient Athens "any stones that might appear interesting to him." With the aid of a corps of artists from Italy, and at his own expense (the British government having declined to further the undertaking), he succeeded in the course of 10 years in detaching from the Parthenon, or in excavating from the rubbish at its base, abundant specimens of the various descriptions of sculptures with which it was ornamented. These consisted of 3 kinds: the colossal statues on the tympana of the pediments, the metopes, and the frieze around the cella. Of the first, the Elgin collection contains statues or fragments of statues from both pediments, those from the eastern, on which was represented the birth of Minerva, being the best preserved, while those representing the contest of Neptune and Minerva for the possession of Attica are chiefly torsos and fragments, procured by excavation. Of the 92 metopes, it contains 15 from the S. side of the building, representing in high relief the combats of the Centaurs and Lapithæ, and a cast from another now in the Louvre. The slabs from the frieze of the cella, representing in low relief the great Panathenaic procession, are the most numerous and the best preserved of all the specimens in the collection. In addition to these, Lord Elgin procured, from the ruins about the Athenian Acropolis, the colossal statue of Bacchus from the choragic monument of Thrasyllus, one of the caryatides from the temple of Pandrosus, a portion of the frieze from the Erechtheum, and fragments of the col-

umns of the Parthenon and Erechtheum; beside numerous inscriptions, including that commemorating the Athenians who fell at Potidæa; urns, &c., taken from various parts of Athens and its neighborhood. The first instalment of these treasures of antiquity arrived in England in 1808, and excited a feeling of admiration and delight, not unmingled, however, with indignation at what was considered the Vandalism of Lord Elgin in removing them from their original resting place, or with doubts as to their artistic value. It was said that he had spent much time and money in procuring indifferent Roman marbles of the time of Hadrian, and the project of purchasing them for the nation was strongly opposed. Lord Byron is said to have carried his feeling on the subject of the alleged depredations of Lord Elgin to such an extent, that on a visit to the Parthenon he inscribed in a conspicuous place: *Quod non fecerunt Gothi, hoc fecerunt Scoti*. Among those who urged upon government the purchase of the marbles was the painter Haydon, whose style received its direction from the contemplation of them, and to whose earnest pleas with men in power was partly attributed the offer of £30,000 for the entire collection, made by Mr. Perceval, the premier, in 1811, which, however, was refused. In 1812, 80 additional cases arrived in England, a number of valuable marbles having previously suffered shipwreck, and in 1815 Lord Elgin offered to make over the collection to the nation for a reasonable sum. In the succeeding year the purchase was effected for £35,000, the actual outlay having exceeded £50,000. The services of Lord Elgin in bringing within the reach of artists, as well as in preserving from the ravages of time, these masterpieces of antiquity, are now fully appreciated; subsequent events having shown that, had he not removed them, the greater part would have been long since destroyed. In the war of Greek independence, and especially in the last siege of Athens in 1826-'7, the Parthenon suffered very serious damage. The Elgin marbles, executed by Phidias or under his direction, exhibit the highest development of Greek art in the maturity of its splendor. As types of beauty they have never been surpassed, and even in their present fragmentary and mutilated condition they afford models of form which the utmost efforts of modern art have not been able to equal. Many casts have been taken from them, of which the free academy of the city of New York possesses a set, and under their influence a national school of sculpture has been established in England.

ELI, judge of the Hebrews immediately before Samuel. He was of the race of Aaron, and officiated as high priest and judge during 40 years; yet he lacked the power to discipline his own family, and a train of woes befell him and his house during the latter years of his life. His piety was exemplary, but his indolence was a source of calamities. After a bloody and disastrous battle with the Philistines, in which

his two sons were slain, and the ark of the Lord was captured, Eli, when hearing the last news, fell back from his chair and broke his neck, at the age of 98.

ELIAS. See ELIJAH.

ELIAS LEVITA (Heb. *Halevi*, the Levite), a learned rabbi and Hebrew author, born at Neustadt in Franconia, or according to some in Italy, in 1472, died in Venice in 1549. He was teacher of Hebrew in Padua from 1504 to 1509, whence he went to Venice and subsequently to Rome. He lost all his property in the sack of Rome by the French in 1527, but enjoyed a reputation for learning and social qualities which enabled him to number bishops and cardinals among his pupils, and made his society sought by princes. He excelled as a critic, grammarian, lexicographer, and poet, and his works were translated and very widely read. Among these were several Hebrew grammars, of which his *Bachur* is the most celebrated, the lexicographical *Tishbi*, and the "Masora of the Masora," the standard book on Hebrew punctuation.

ÉLIE DE BEAUMONT, JEAN BAPTISTE ARMAND LOUIS LÉONCE, a French geologist, born at Canon, Calvados, Sept. 25, 1798. In 1821 he undertook, by order of the government, a series of metallurgical explorations, and was made on his return in 1824 a mining engineer. In 1829 he became professor at the school of mines, in 1832 at the college of France, and engineer-in-chief in 1833. After the death of François Arago he was made perpetual secretary of the academy of sciences. Napoleon III. appointed him senator. He was appointed in 1823, together with Dufrenoy, to aid M. Brochant de Villiers in preparing the materials for the geological map of France; and in this commission they were charged to visit England, where a similar work was in progress, and at the same time to examine the metallurgical operations there practised, and collect full details, the knowledge of which might aid in developing the same branches of industry in France. The results of their investigations were published by Dufrenoy and Élie de Beaumont, in a work entitled *Voyage métallurgique en Angleterre* (1827), illustrated with numerous plates, and afterward enlarged with the aid of MM. Léon Coste and Perdonnet. Élie de Beaumont now devoted himself almost exclusively to geological researches, while engaged upon the preparation of the map of France, and published frequent papers in the *Annales des mines* and other scientific journals. In his *Notice sur les systèmes des montagnes* (1852), he endeavored to prove that mountain chains are to be classed according to the direction of their range, all those lying parallel with the same great circle of the earth, wherever they may be found, having been uplifted suddenly during the same geological epoch. The uplifting, he contended, was caused by the movement resulting from the contraction of the crust of the earth in the course of the secular refrigeration of the planet. These violent effects thus produced were only occasion-

ally exhibited in the long history of the globe during short periods of disturbance which succeeded the more extended periods of repose. In the latter were deposited the sedimentary rocks of the peculiar types of the period, inorganic and organic, and every change to another series of rocks was evidenced by the formation of chains of mountains having a different direction from those which preceded them. Further, those stratified rocks of the same epoch must have the same direction or strike. He described in the last edition of his work the features of no less than 95 systems of mountains; and the facts he collected added largely to the geological knowledge of the day.

ELIJAH, a Hebrew prophet, whose history is given in the last chapters of the 1st book of Kings, and in the opening chapters of the 2d. According to this he suddenly appeared before King Ahab, declaring that as a punishment for his iniquities neither dew nor rain should fall for years, until he himself announced the change. He took refuge from the wrath of the king in the desert, by the brook Cherith; and after the drying up of the brook he proceeded to Zarephath, where he was supported by a poor widow, for whom his presence was a source of blessings during the distresses of the time. After drought and famine had desolated the country during 3 years, he reappeared to the king, offering to demonstrate the vanity of the worship of Baal. He challenged the idolatrous priests, 850 in number, who had followed in the train of Queen Jezebel, to meet him upon Mt. Carmel, and defied them to make fire fall from heaven to consume their sacrifice. The long prayers of the Baalites were without success, but on Elijah's short prayer the fire came down and consumed not only the bullock but the altar. The people instantly massacred the priests, and then Elijah promised an end to the famine, and there was an abundant rain. But Jezebel swearing revenge for the destruction of the priests, Elijah again fled to the wilderness of Mt. Horeb and hid himself in a cavern. Then he was commanded to return and anoint Hazael king over Syria, Jehu over Israel, and Elisha prophet in his own place. On his way he found Elisha and made him his disciple, and as he appeared again before Ahab, guilty of the blood of Naboth, the king humbled himself and repented. Ahaziah, his son, who succeeded to the throne, fell ill, and Elijah announced to him through his agents that his sickness would end in death. Ahaziah sent a captain and 50 armed men to seize Elijah; but fire from heaven consumed the band. A second company met with the same fate. At length he appeared personally before the king and repeated his announcement. His mission was now accomplished. He made a visit to the school of the prophets at Bethel, and having, in company with Elisha, crossed the Jordan, the waters of which he divided by smiting them with his mantle, he was taken up into heaven by a whirlwind, in a char-

lot of fire drawn by horses of fire. The date of this event is fixed in the early part of the 9th century B. C.

ELIMINATION (Lat. *eliminare*, to turn out of doors), the separation and exclusion of some particular substance from a compound, or of some particular symbol from an algebraic expression, thus simplifying the compound or expression, and rendering it capable of further analysis and use.

ELIOT, JOHN, commonly called the "Apostle of the Indians," an American clergyman, born in Nasing, England, in 1604, died in Roxbury, Mass., May 20, 1690. He was educated at Cambridge, was for some time an instructor of youth, and in 1631 came to Boston, Mass., where he preached to the church of Mr. Wilson, who was then in England. In 1632 he was settled as teacher of the church in Roxbury, where he remained to the end of his days. Being impressed with the benighted condition of the Indians, whom he fancied to be the descendants of the lost tribes of Israel, and the legislature having passed an act for the propagation of the gospel among them, he commenced preaching regularly to them in their own language at Nonantum, now a part of Newton. He had acquired their language through the assistance of an intelligent Indian servant in his family who had learned English. The first service was held Oct. 28, 1646. After prayer he addressed them in a sermon, in which he stated the leading doctrines of Christianity, and applied them to their condition, inviting his hearers at the close to ask any questions that might occur to them. One asked whether God could understand prayers in the Indian language; another, how could there be an image of God since it was forbidden in the 2d commandment; another, how the Indians could differ so much from the English in their views of religious truth if they all at first had but one father; another, how came the world so full of people if they were all once drowned in the flood. The conference lasted 3 hours, and was followed by others in which similar queries were propounded by the Indians, one of whom, very aged, inquired, with tears, whether it was too late for such an old man as he to repent and be saved. Eliot was strongly opposed by some of the sachems and conjurers, who threatened him with violence if he did not desist from his labors; but his answer was: "I am about the work of the great God, and he is with me, so that I neither fear you, nor all the sachems in the country. I will go on; do you touch me if you dare." A settlement of "praying Indians" was soon formed at Nonantum, which in 1651 was removed to Natick, where in 1660 an Indian church was organized, and the community flourished for many years. Eliot travelled extensively, making missionary tours every fortnight; planted a number of churches; visited all the Indians in the Massachusetts and Plymouth colonies, and once preached the gospel to the famous King Philip, who rejected it in disdain.

In these labors of benevolence he cheerfully encountered both dangers and hardships. In one of his letters he says: "I have not been dry night or day from the third day of the week unto the sixth, but so travelled; and at night pull off my boots, and wring my stockings, and on with them again, and so continue; but God steps in and helps." He induced large bodies of Indians to give up their savage customs and habits, and form themselves into civilized communities; led many persons to engage in the missionary work among them, and lived to see no fewer than 24 of them become preachers of the gospel to their own tribes. His influence over the Indians was almost unbounded. He protected them in 1675, during Philip's war, when some of the people of Massachusetts had resolved to extirpate them; and though he suffered much abuse for the part he took, nothing could shake his faithful friendship for them. At the age of 80 he offered to give up his salary from the church in Roxbury, and desired to be released from his labors as their teacher; and when, from increasing infirmities, he could no longer visit the Indians, he persuaded a number of families to send their negro servants to him every week, that he might instruct them in the word of God. His declining years were without pain or disease. Mr. Eliot was one of the most laborious and useful ministers of his day; his discourses, unlike those of most preachers of the time, were direct and free from pedantry, and everywhere acceptable. In all circumstances his first inquiry was, how he might do some good to those about him. His manner of living was very simple. He allowed himself but little sleep; a single plain dish furnished his ordinary repast. He gave to the Indians most of his annual salary of £50, which he received from the society for propagating the gospel; and it is related that on one occasion, when the parish treasurer was paying him, he tied the ends of the handkerchief into which he put the money in as many hard knots as possible, to prevent Mr. Eliot from giving it away before he should reach home. Calling at once, however, on a family suffering from sickness and want, he told them God had sent them relief, and began to untie the knots; but becoming impatient, he gave handkerchief and all to the mother, saying: "Here, my dear, take it; I believe the Lord designs it all for you." Among Mr. Eliot's peculiarities was a deep-rooted prejudice against wigs and long hair, preaching and praying vehemently against both, and attributing to them the evils under which the country suffered. He had the same strong aversion to the use of tobacco, and denounced it in the severest terms. Richard Baxter said of Mr. Eliot: "There was no man on earth that I honored above him." All New England bewailed his death as a great and general calamity; and Cotton Mather tells us: "We had a tradition that the country could never perish as long as Eliot was alive."—A list of the published works of Mr. Eliot may be found in his life, by the Rev. Convers Francis, in Sparks's "American Biography." Among them are ac-

counts of the progress of the gospel among the Indians; the "Christian Commonwealth," published in England about 1660, which, when received in Massachusetts, was regarded as seditious, so much so that the governor and council required Mr. Eliot to retract its teachings, because opposed to the monarchy of their native country; an Indian grammar (1664); the psalms translated into Indian metre (1664); and a harmony of the Gospels, in English (1678). His great work, however, was the translation of the Bible into the Indian tongue; the New Testament was first published in 1661, and the Old in 1663; and both were issued in subsequent editions. This work was published at Cambridge, and was the only Bible printed in America until a much later period. The longest single word in it is "Wutappesittukqussunnoohwehtunkquoh," signifying "kneeling down to him," in Mark i. 40; which illustrates the jest of Cotton Mather, who said he thought the words of the language must have been growing ever since the dispersion at Babel.—JARED, grandson of the preceding, and minister in Killingworth, Conn., born Nov. 7, 1685, died April 22, 1763. He was an able and constant preacher, a botanist, and a scientific and practical agriculturist, was the first to introduce the white mulberry tree into Connecticut, and discovered a process of extracting iron from ferruginous sands. He was also regarded as the first physician of his day in the colony; and such was his success in the treatment of insanity and chronic complaints, that he was sometimes sent for to Newport and Boston, and was more extensively consulted than any other physician in New England. In his multiplied pursuits his judgment seemed always good, and his success almost unfailing.

ELIOT, JOHN, D.D., an American clergyman, born in Boston, May 31, 1754, died there, Feb. 14, 1813. With his friend Dr. Belknap he coöperated in establishing and sustaining the "Massachusetts Historical Society," to the publications of which he contributed many valuable papers. He was much engaged in biographical and historical researches, and in 1809 published his well-known "New England Biographical Dictionary." He also published a number of sermons on different occasions, and several memoirs of distinguished persons.

ELIOT, SAMUEL, an American author, born in Boston, Dec. 22, 1821, a son of William Harvard Eliot, and grandson of Samuel Eliot, who founded the Eliot professorship in Harvard college. He was graduated at Harvard college in 1839, with the highest honors of his class, though one of the youngest members. Having decided upon a life of business, he passed 2 years in a counting room in Boston, after leaving college; but he abandoned his original purpose at the end of this period. The next 4 years were spent by him in foreign travel and in studies abroad. In Rome, in 1845, he formed the plan of writing a history of liberty, and began upon it. For some years after his return he resided in Boston or its immediate neighborhood, en-

gaged in literary labor, but also giving much time and thought to the business of practical teaching. Beside private pupils, he gave gratuitous instruction to classes of young working men, and organized a charity school for vagrant children. His first publication, a small volume, produced in Boston in 1847, entitled "Passages from the History of Liberty," traced the career of Arnold of Brescia and other early Italian reformers, of Savonarola, of Wycliffe, and touched upon the war of the communities in Castile. The first portion of the elaborate work to which he had chiefly devoted himself, appeared in 2 vols. 8vo. in New York in 1849, entitled "The Liberty of Rome." A second revised edition appeared in Boston in 1853, entitled "The History of Liberty. Part I. The Ancient Romans." In the same year was published in Boston a further portion of the same work in 2 vols. 8vo., called "The History of Liberty. Part II. The Early Christians." The author is now engaged upon a third part of this work, in which he will treat of the history of liberty during the papal ages. These histories are characterized by great depth and patience of research, a philosophical method, and a reverential and religious tone; but they are not popular either in essence or in form, and they have not received from the general public the attention which their substantial merits deserve. In 1856 he published in Boston "A Manual of United States History, 1492-1856," a carefully prepared work, distinguished for fidelity of research and condensed clearness of statement. Mr. Eliot has also been an occasional contributor to the periodical literature of the country. He is at present professor of history and political science in Trinity college, Hartford. A man of earnest religious faith, he believes that education in America needs a stronger infusion of the religious element, and his life, his writings, and his practical teachings in his department, are shaped and colored by this ruling idea.

ELLIOTT, GEORGE AUGUSTUS, Baron Heathfield, a British general, born in Stobbs, Roxburghshire, Scotland, in 1718, died in Aix la Chapelle, July 4, 1790. He was educated at the university of Leyden, and subsequently studied the art of war at the celebrated school of artillery at La Fère. He entered the British army in 1735, and from that period until the close of the 7 years' war was actively employed at home and abroad, showing equal capacity as an officer of cavalry, of engineers, and of the staff. He distinguished himself greatly at Dettingen, and many other actions in Germany and the Netherlands, at the head of his celebrated regiment of light horse. After the peace he obtained the rank of lieutenant-general, and in 1775 was appointed governor of Gibraltar, the defence of which place for more than 3 years against the combined French and Spanish forces was the chief exploit of his life, and one of the most memorable events in military annals. During the grand attack (Sept. 13, 1782), several hundred pieces of heavy ord-

nance were directed against the fortress, beside the batteries of 47 ships of the line, of 10 battering ships of peculiar construction and great strength, and of innumerable frigates and gunboats; but owing to the exertions of Gen. Elliott the enemy were beaten off with immense destruction of life and ships, and with but trifling loss to the besieged. On his return to England he received the thanks of both houses of parliament, and was made a knight of the bath by George III.; and on July 6, 1787, he was raised to the peerage as Baron Heathfield of Gibraltar, and a pension was settled on him and his successor.

ELIQUATION (Lat. *eliquo*, to melt), the method of separating metals from each other by melting out the more fusible at temperatures below the melting point of another with which they may be alloyed. It was formerly largely practised in assaying, particularly in separating alloys of copper and silver. Lead was first melted with them, and the mixture being then carefully remelted upon an inclined iron plate, the lead first melted and flowed down a channel in the plate, leaving the copper behind. The silver was afterward easily separated from the lead by cupelling. (See **ASSAYING**.)

ELIS, or **ELEA**, in ancient Greece, a country of the Peloponnesus, extending along the Ionian sea from the promontory Araxus to the river Neda; greatest breadth about 35 m., from the promontory of Ohelonatas to the foot of Mount Erymanthus, where the boundaries of Elis, Arcadia, and Achaia come together; area, about 1,000 sq. m. It contained the western slopes of the Achaian and Arcadian mountains, Erymanthus Pholœ, and Lycæus, and though its surface was for the most part uneven, it had many valleys and hillsides of great fertility. Its principal rivers were the Alpheus and the Peneus. The whole territory included 8 districts: Elis, in its narrower sense, or Hollow Elis; Pisatis, separated from the first by an arm of the Pholœ mountains; and Triphylia, lying S. of the Alpheus. Of these, Hollow Elis, so called from its being a vale set in a circle of mountains, was the most northern and the most fertile. Here, and nowhere else in Greece, grew the flax called *bysus*, as fine but not as yellow as that of the Hebrews, as was remarked by Pausanias. At the time of the Doric invasion, Oxylyus led the Heraclidæ south by the more difficult way of Arcadia, lest they should see and be attracted by the richness of this plain. Hollow Elis never contained more than 3 cities, Elis, with its harbor Cyllene, and Pylus. These were unwalled, and protected only by the sanctity of the country, which by the common law of Greece was regarded as inviolable, on account of its possession of the temple of the Olympian Zeus on the banks of the Alpheus. Here, once in every 4 years, all the states assembled for religious games. This sacred character of Elis was, however, disregarded during the Peloponnesian war by the Athenians. Afterward King Agis of Sparta pressed across the Larissus to at-

tack Elis, but on the first attempt fled alarmed by an earthquake, and failed in a subsequent attack. Cyllene is mentioned in Homer's catalogue of ships, but of the Elean Pylus no sign remains but the name, it having been destroyed even in the heroic times of Greece. Hollow Elis is the scene of the legend of the Augean stables cleansed by the current of the Peneus, which Hercules made to pass through them. The Elean horses, too, were famous for bearing off the Olympic prizes, and merited the praises of Pindar. Pisatis, which was the lower valley of the Alpheus, had 8 cities, 2 of which, Pisa and Salmone, are celebrated in the legends of Cænomaus, Pelops, and Salmoneus. From the time of the Doric invasion there was hostility between the proper Eleans and the Pisatians, caused by the claim of the former to direct the Olympic games. This jealousy gave rise to several wars and alternations of supremacy. The Eleans, finally victorious in the 50th Olympiad, destroyed the city of Pisa. In this district was Olympia, the seat of the most famous of the Greek games, and the quaternial scene of the most splendid of Greek assemblages. Triphylia, the smallest and the southern division of Elis, was separated from Messenia by the Neda, and was fertile only in the interior. Here was Mount Minthe, the highest in Elis, one of the seats of the worship of Hades. Some of the cities of Elis hardly yielded to Corinth and Sparta in the magnificence of their monuments and temples. The Eleans took part in the Trojan, Peloponnesian, and the other general Grecian wars, and were almost constantly in strife with some one of their neighbors. They retained the celebration of their renowned Olympic games till A. D. 394, when the festival was abolished by the emperor Theodosius. Two years later the country was laid waste with fire and sword by Alaric. Again in the middle ages Elis became of some importance in the hands of French adventurers, and subsequently of the Venetians. But the memory of its ancient religious character, and traditions of its cultivation and large and active population, give to it its only modern interest.

ELISABETGRAD, **ELISAVETGRAD**, or **YELISAVETGRAD**, a fortified town of S. Russia, in the government of Cherson, 180 m. N. from the town of that name; pop. about 10,000. It is situated on the river Ingul, is the capital of a circle of its own name, is hexagonal in shape, fortified and well built, is the headquarters of the military colonies E. of the Bug, contains a large hospital and 5 churches, has considerable trade, and the principal annual fair in the government. It was founded in 1754, and named after the empress Elizabeth.

ELISHA, son of Shaphat, a Hebrew prophet, whose history is given in the 2d book of Kings. He was ploughing with 12 yoke of oxen, when Elijah, returning from Horeb, called him to the prophetic office. At the moment when Elijah disappeared from the earth, Elisha received his mantle, and was recognized by the other proph-

ets as their spiritual chief. He divided the waters of the Jordan by extending over them the robe of his master, rendered the bitter fountain of Jericho sweet by casting salt into it, cursed the children of Bethel, who mocked him, and were devoured by 2 bears, predicted the victory of Jehoram and Jehoshaphat over the Moabites, restored the fortune of a widow persecuted by her creditors, raised to life the son of a woman of Shunam who had given him hospitality, and cured the leprosy of Naaman. He defeated all the projects of Benhadad, king of Syria, against Israel, caused the host sent to capture himself to be smitten with blindness, and having shown them how easily he could destroy them, dismissed them, astonished at his power and moderation. Samaria being reduced to extreme famine by siege, Elisha predicted incredible abundance, which was suddenly obtained by the panic and flight of the Syrian army, leaving their tents filled with gold and provisions. He foretold the death of Benhadad, and the succession of Hazael, his murderer. Upon his deathbed he was visited by King Joash, to whom he promised 3 victories over the Syrians. His death is fixed in the latter part of the 9th century B. C.

ELIXIR (Lat. *elixo*, to boil, or perhaps a word of Arabic origin), applied in old pharmacy to certain extracts obtained by boiling, as elixir of vitriol, a mixture of sulphuric acid with some aromatic tincture; and in modern pharmacy the name is retained for various tinctures made up of several ingredients. The alchemists applied it to a number of solutions they employed in the transmutation of metals.

ELIZABETH, a city, capital of Union co., N. J., on Elizabethtown creek, $2\frac{1}{2}$ m. from its entrance into Staten Island sound, and 5 m. S. W. from Newark; pop. in 1855, 8,978. It is regularly built on high ground with straight streets, shaded with trees, and contains a number of excellent schools, the county offices, a bank, a newspaper office, several large manufactories, and 12 churches, viz.: 1 Baptist, 8 Episcopal, 3 Methodist, 3 Presbyterian, and 2 Roman Catholic. Vessels of 300 tons can reach Elizabethport, $2\frac{1}{2}$ m. from the city, at the mouth of the creek, and near the entrance of Staten Island sound into Newark bay, and vessels of 30 tons can ascend to Elizabeth. The New Jersey central and the New York and Philadelphia railroads pass through the city. It was settled in 1665, and was long the capital and chief town of the state. It was formerly called Elizabethtown.

ELIZABETH, second queen regnant of England, and last sovereign of the Tudor line, daughter of Henry VIII. and Anne Boleyn, born at the palace of Greenwich, Sept. 7, 1538, died March 24, 1603. She was virtually made heirless presumptive to the throne immediately after her birth, by act of parliament, to the exclusion of her sister Mary, daughter of Catharine of Aragon, who was more than 17 years her senior. The king, though bitterly disappointed in the sex of the child, showed attachment to her, and

interested himself in her education. He purposed wedding her to the 8d son of Francis I. of France. In her 8d year her fortunes were clouded by the occurrence of that tragedy which sent her mother to the scaffold. Elizabeth was in her turn declared illegitimate, and fell into contempt. The birth of her only brother, afterward Edward VI., happened in 1537, and her first public act was to bear the chrism at his christening, she being herself carried in the arms of Lord Hertford. She was educated by Lady Bryan, a superior woman, and early showed talent. To her brother she became attached. With Henry's last 3 wives she was on the best of terms. At 10 years her hand was offered to the earl of Arran, but refused. A marriage between her and Prince Philip of Spain was talked of in 1545. The preceding year she had been restored to her right of succession, but the act declaring her illegitimate was never repealed. She had already become very learned, understanding the Latin, French, Italian, Spanish, and Flemish languages. She translated a work from the Italian, and dedicated it to her last stepmother. Her poetry was very good for a princess; but her favorite study was history. She is known to have shared the instruction received by her brother from some of the most learned men of England. Henry dying in Jan. 1547 (N. S.), Elizabeth found herself, by his will, the next person in the order of succession to Mary, and in other respects liberally provided for. Lord Seymour of Sudley, an uncle of the king, endeavored to get her for his wife; but he failed, and married Catharine Parr, Henry's last wife, at whose instance Elizabeth had rejected him. Her studies were continued, and she became the pupil of Roger Ascham, on the death of William Grindal, when she was 16. With him she read in Latin the works of Livy and Cicero, and in Greek those of Sophocles, the select orations of Isocrates, and the New Testament. Elizabeth was residing with her stepmother, and the freedom she allowed Lord Seymour caused much scandal, and led to her removal to Hatfield. After his wife's death, Seymour renewed his acquaintance with Elizabeth, but his arrest and execution on the charge of treason prevented the success of his designs. Elizabeth, on hearing of his death, merely said that there had died a man of much wit and very little judgment—words which accurately describe the man. Her reputation, however, suffered severely, and the most scandalous stories were current respecting her and Seymour. It is certain that she long cherished a regard for his memory. An attack of illness endangered her life, and led to her being better treated, though she was not allowed to see the king, whose affection for her was unbroken. In 1551 she was restored to favor. She was now regarded as being in some sort the rival of Mary, and as the chief person in the Protestant party, as Mary was at the head of the Catholics. The plan of Dudley, duke of Northumberland, to exclude both ladies from the throne, and to secure it for Lady Jane Grey, whom he had caused to

marry one of his sons, put an end to this rivalry. The king was Northumberland's tool, and was not allowed to see Elizabeth in his last days. He is supposed to have been completely estranged from her. On his death, the duke offered Elizabeth a large sum of money, and a valuable grant of lands, if she would acquiesce in the new order of things; but she referred him to Mary, during whose life she had nothing to resign. She did not raise a force to aid Mary, as it was not in her power to do so, but joined her soon after her success, in 1553, at the head of a body of troops. They were on the best of terms, but in a month they became enemies. Mary's stubborn fidelity to the old faith offended many of her subjects, who looked to Elizabeth as their future sovereign, the queen having passed middle life, and being single. Their relative positions were sufficient to cause enmity between them, and Elizabeth's refusal to attend mass offended the sovereign and her Catholic advisers. After much quarrelling, the princess affected to give way, and attended the queen at mass. Her object was to have her right to the succession admitted at the coronation, in which she succeeded. The sisters needed each other's support. The estrangement, however, was renewed, when an act of parliament was passed, declaring valid the marriage between Henry VIII. and Catharine of Aragon, from which Elizabeth's illegitimacy followed, though it was not set forth in words. A conspiracy is supposed to have been formed for the overthrow of Mary's government, and the marriage of Elizabeth to Courtenay, earl of Devonshire. Mary consented to her sister's request that she might retire to the country, but withdrew the favor, and ordered Elizabeth to remain in the palace, and affronted her on the point of precedence. On this, Elizabeth refused to go to the royal chapel, and remained in her chamber. Grave accusations were preferred against her, but she disproved them, a reconciliation was effected, and she was allowed to go to the country. Here she refused to marry the duke of Savoy, and also declined the hand of the prince of Denmark. The conspiracy to elevate her and Courtenay to the throne having become known to the government, those engaged in it rose in rebellion, and Mary ordered Elizabeth to return to court. On the plea of illness she did not comply. Wyatt's rebellion was put down, and some of the rebels accused her of being in the plot, while there were other circumstances that bore against her. A royal commission was sent to remove her to London, which was done, though she was very ill. She was lodged at Whitehall, Mary refusing to see her. The royal councillors were divided, some being in favor of her execution, while others were more merciful. Finally she was sent to the tower, March 17, 1554, where she was examined. She was forced to hear mass. Wyatt exonerated her on the scaffold of being privy to his intended rebellion, but his language was ambiguous, and there seems little reason to doubt her complicity in the plot. The ambassador of Charles V., anx-

ious for the interests of Philip, Mary's intended husband, warmly urged Elizabeth's execution. Mary, whose conduct throughout was not unkind, and who behaved with singular moderation for a crowned head of those times, would not listen to his entreaties, and soon gave orders for her sister's removal from the tower. Elizabeth was sent to Woodstock, where she remained in detention for some time, and professed herself a Catholic. The queen was married in July, 1554, to Philip II. of Spain, and her belief that she was to give an heir to the crown had a good effect on Elizabeth's fortunes; she was now taken to London, had an interview with Mary, and appeared publicly at court. Though treated with much respect, she was not made free until some months later, returning to Woodstock, and sent thence to Hampton court. Her liberation is attributed to Philip, and she was allowed to reside at Hatfield, but with a sort of keeper in her household. She was visited by the queen, and went herself to court. The object of many plots, her life continued to be unpleasant, and at one time she thought of flying to France. Overtures of marriage were made to her from various quarters, but she would not listen to them. Philip, who now treated her with marked friendship, on politic grounds, was anxious that she should marry his friend Philibert of Savoy, but all his endeavors were fruitless, and he could not prevail upon his wife to coerce her sister's inclinations. Mary and Elizabeth were on good terms during the last months of the former's life. The queen, anticipating her husband's request, declared Elizabeth her successor, shortly before her death, exacting, however, a profession of adherence to the old religion. Affecting to feel hurt that her Catholicism should be doubted, the princess "prayed God that the earth might open and swallow her alive, if she were not a true Roman Catholic." She declared that she prayed to the Virgin, and on the day before she became queen the Spanish ambassador wrote to his master that she had told him that she acknowledged the real presence in the sacrament. Mary died Nov. 17, 1558, and Elizabeth ascended the throne without opposition. Cecil was appointed her principal secretary of state, and Nicholas Bacon lord keeper. The queen continued to conform to the Catholic worship until Christmas morning, when she took the final step that placed her at the head of the Protestant world, by refusing to hear mass in the royal chapel. Other changes were made, but her coronation was according to the forms of Catholicism. She sent friendly messages to Protestant sovereigns, and directed her minister at Rome to assure Paul IV. that no violence should be done to the consciences of Englishmen; but the pontiff made only sharp comments on the message, declared she was not legitimate, and required her to submit her claim, as against that of Mary Stuart, to his arbitration. She recalled her minister, whom the pope frightened into staying at Rome under the threat of excommunication. A bull was issued against Elizabeth soon after, though she was

not expressly named in it. The religious change went on, though Elizabeth was averse to innovations, and would have preferred to proceed so slowly as to have virtually kept things in the state she had found them. Catholic and Protestant services were even ludicrously mixed up in her public worship. This could not last, and 13 bishops were deprived of their sees by parliament for refusing to take the oath of supremacy. The church of England was restored, and the use of the Bible in English was legalized. Philip of Spain sought her hand, and wrote to her often; but though she played her game with much skill, England being in a very depressed state, she would not accept the offer. Parliament formally acknowledged her title without any allusion to her mother; but she never vindicated her mother's name and fame, which has been a significant fact in the way of those who have supported Anne Boleyn's cause. Elizabeth's conduct was purely political, and it should be recollected that she had never known her mother at a period of life when it is possible to form durable affections. By the treaty of Cateau Cambrésis (April, 1559) peace was restored, France agreeing to give up Calais in 8 years. It was not until 6 months after her accession that the Catholic service was finally discontinued in Elizabeth's private chapel. At first she would not take the title of head of the church, assuming that of its governess; but at a later period she became less discriminating, and asserted her supremacy arbitrarily. Many princes and nobles continued to sue for her hand; and it shows how different was opinion then from what it now is, that even a plain knight, Sir William Pickering, a man of good talent but moderate means, was seriously spoken of as her husband. In France the English throne was claimed for Mary, queen of Scots, wife of Francis II.; a foolish pretension, destined to have bloody consequences. Elizabeth early began that systematic interference with Scotch affairs which lasted during her entire reign, making of Scotland an English province in fact. The party of the reformation was enabled to triumph there through her aid. Pius IV., a new pope, sought to win the queen back to the church of Rome by gentle means, but unsuccessfully. She restored the currency to sterling value in 1560, a reform that did much to promote the prosperity of her subjects. Aid in money, arms, and men was sent to the French Huguenots, and secret assistance to the Protestants of Flanders. When the queen of Scots sought a safe passage from France to her kingdom, Elizabeth refused her request, and it is believed that she endeavored to seize her person. In 1563 parliament entreated the queen to marry, the question of the succession being one of much interest to all classes of her subjects, who had not yet got free from the terror caused by the wars of the roses. Candidates for her hand continued to spring up, at home and abroad. The most prominent Englishman who aspired to the honor was Henry Fitzalan, last (and 18th) earl of Arundel of that

name, a man of nobler lineage than her own. Though she was entreated to acknowledge Mary Stuart as her heiress presumptive, she would not do so, and the question was left open, to the grief of the people. The expedition she sent to France failed. She recommended Lord Robert Dudley as a husband to Mary Stuart, before he had been made earl of Leicester, though his object was to marry herself. She was offered the hand of Charles IX. of France, but though pleased with the offer she would not accept it. Another suitor of the highest rank was the archduke Charles, son of the German emperor. Leicester approved of this match. The fortunes of this new noble were rapidly rising, and though he and the queen occasionally fell out, they were soon reconciled, and to his increased gain. Their intimacy began early, in the days of Elizabeth's adversity, and lasted until the earl's death. He even patronized Cecil, to whom in talent he was so inferior, as well as in solid influence. The intimacy between the queen and the earl caused scandalous stories to obtain currency, which had no other foundation than some imprudent acts could furnish. Being requested by Charles IX. to select two English nobles to be made knights of St. Michael, she named Leicester and the duke of Norfolk. Her marriage with the favorite was expected daily. The marriage of Darnley and Mary Stuart annoyed her; and the birth of a son from that union caused alarm in England, as showing that the crown might pass to a Catholic. Parliament being summoned in Oct. 1566, one of the first acts of the commons was to vote that the bill for supplies should be accompanied by one for the settlement of the succession; for this Elizabeth hotly rebuked them. Even Leicester, whose schemes had been traversed by Cecil, was one of the leaders of the opposition on this occasion. In November she was waited upon by a deputation from both houses, and entreated to marry, or to name a successor. She endeavored to reason them out of their obstinacy, and as to the succession, she said they should have the benefit of her prayers. The commons were stubborn, but the dispute was compromised, the queen taking half the money without naming her successor. At this time she was dabbling in alchemy, believing in the quackery of Dr. Dee, whom she had consulted at the beginning of her reign for an auspicious day for her coronation. She made him chancellor of St. Paul's. The murder of Darnley led to the overthrow of Mary Stuart, and to her flight to England the next year (May, 1568), when she was made Elizabeth's prisoner, in violation of the laws of hospitality and the laws of nations. Mary submitted her case to be tried by English commissioners, who were a packed body, and incapable of deciding justly. The serious internal troubles of England in this reign began with the imprisonment of Mary; and those from without began to assume a critical character about the same time. The asylum England afforded to those who fled from persecution in Flanders offended Spain. The

English flag was insulted in the gulf of Mexico, and the English minister at Madrid badly treated. The queen retaliated by seizing treasure that had been found in Spanish vessels which had taken refuge in English ports; and when Alva laid an embargo on Englishmen and their property, she arrested all the Spaniards in England, not even excepting the ambassador. She corresponded directly with Philip II., but that monarch took a high tone, and threatened war. The duke of Norfolk had become attached to Mary Stuart, and Elizabeth bade him be on his guard. He was arrested and imprisoned. The great northern rebellion then broke out (1569), headed by the Catholic earls of Westmoreland and Northumberland, but was rapidly crushed by the earl of Sussex, and 800 of the rebels were executed. In 1570 the queen was excommunicated by Pope Pius V., and a copy of the bull was fastened on the gate of the episcopal palace of London, by a Catholic named Felton, who was racked and executed. After the failure of another attempt to get up a marriage between the queen and the archduke Charles, it was proposed that she should marry the duke of Anjou, afterward Henry III. of France, and last of the Valois. When the council was informed of this, one of them observed that the duke was rather young for the queen, which enraged her. In this, as in all her negotiations of a similar character, she does not seem to have been sincere; but it was always a source of anger when any one of her innumerable suitors saw fit to marry some other lady. She opened the new bourse, built by Sir Thomas Gresham, in 1571, and named it the royal exchange. Cecil was now created Lord Burleigh, and made lord high treasurer. Sir Thomas Smith was made principal secretary of state. Hatton now began to attract attention, being high in the queen's favor because of his personal accomplishments and beauty; and her reputation has been assailed on account of her fondness for him. For his good she spoiled the bishop of Ely of much church property, and wrote him a truculent and blasphemous epistle in 8 lines. The French marriage project halting, because of the aversion of Anjou to the mature queen, his mother had the impudence to propose his younger brother Alençon in his place, who was Elizabeth's junior by 22 years, and as hideous in person as he was morally depraved. Anjou affected to change his opinion, and the negotiation was resumed. The parliament of 1571 vexed her much, but she was beaten in her attempts to rule it. The emperor Maximilian II. offered the hand of his son Rodolph to the queen, who was more than old enough to be his mother. Henry of Navarre was also placed at her disposal. But she favored Anjou most, much to his dread; and it was to avoid his open rejection of her hand that she rejected his on religious grounds, according to those who think she was sincere. Philip II. was now engaged in a plan involving the assassination of Elizabeth. With this plot Norfolk and Mary Stuart had some connection, but probably with-

out knowing the viler features of it. It was discovered, and Norfolk was executed. The Alençon marriage project was now resumed. Parliament passed a bill to put Mary Stuart to death, but Elizabeth would not give her consent to it. Meantime, fanaticism in France caused the St. Bartholomew massacre in 1572, which event made the English reformers clamorous for Mary's blood; and while Elizabeth would not consent to the execution of her unlawfully detained prisoner, she agreed to a project for giving her up to her Scotch rebel subjects, who were to murder her in 4 hours after obtaining possession of her person. This villanous business came to nothing, because of the Scotch leaders in it insisting upon conditions to which the English could not agree. Mary was still held in confinement. In 1575 the Dutch offered their government to Elizabeth, whom they respected as descended from Philippa of Hainaut. She did not at first help them, and it was not until 1578 that she agreed to aid them with money and men, on conditions by which she could not lose any thing. When Sir Francis Drake returned from his voyage around the world, Elizabeth visited him on board his ship, knighted him, and shared the spoil he had piratically taken from the Spaniards. Ireland gave her great trouble, and the contest which was waged there by Lord Mountjoy was known among the people as "the hag's war," in bitter derision of the queen. Conspiracies began to multiply around her, naturally having Mary Stuart for their central figure. The Jesuits were conspicuous in these plots, in one of which the Spanish minister Mendoza was implicated, and forced to leave the country. Many persons were executed and others imprisoned. Philip Howard, earl of Arundel, son of the duke of Norfolk, was condemned to death, and died in the tower, after a long imprisonment. An association to protect the queen against "popish conspirators" was formed by Leicester, and was converted into a statute by parliament, which actually prepared the way for the murder of Mary Stuart, should Elizabeth be assassinated in her name. Though she continued to refuse the sovereignty of the Dutch, she afforded them more aid, and honorably banished Leicester to their country, at the head of an army; but the distinctions heaped upon him in Holland greatly offended her. The discovery of Babington's conspiracy proved fatal to Mary Stuart, despite the fact that nothing could be proved against her. Her trial was a serious farce, and had its appropriate ending in the open murder perpetrated at Fotheringay (Feb. 8, 1587). It is now pretty well established that Elizabeth's signature to Mary's death warrant was a forgery, and it is beyond doubt that it was sent to Fotheringay castle without her knowledge or sanction. Burleigh was the sender of it, and the forgery is supposed to have been perpetrated by the order or under the direction of Walsingham. Elizabeth was anxious for Mary's death, and sought to have her privily assassinated, but did not mean to have her openly

executed. She feared the effect of so bold an act on many accounts, but mostly because of the tendency it would have to encourage those writers and speculators who then argued in favor of the right of the people to dethrone and to punish kings. She also feared its effect on foreign sovereigns. Her ministers' fears were of a different character, and were removed by Mary's murder. They feared that Mary would survive Elizabeth, and either would succeed her, or that her claim would cause a succession war, the traditional aversion of English statesmen. Angry as she was, Elizabeth dared to punish no one but secretary Davison, who was only a tool of the higher ministers; for not only had foreign affairs assumed a serious aspect, but the killing of Mary was unquestionably a popular act with the ruling classes and party. The Scotch people were enraged, and gladly would have assailed their old enemy; but their king had little affection for a mother whom he never had known, and he expected to be Elizabeth's successor. The condition of France left no room for fear on that side; but the pope and the king of Spain were active enemies. Sixtus V. anathematized Elizabeth, and proclaimed a crusade against her. Philip II. laid claim to the English crown, as legitimate heir of the house of Lancaster, in virtue of his descent from two daughters of John of Gaunt, who had been queens of Portugal and Castile. He made open preparations to enforce this claim, and the pope promised large conditional aid. Meantime, Drake ravaged the coasts of Spain, preyed on her commerce, and made a successful attack on the shipping in the harbor of Cadiz. The English were not backward in preparing to meet Philip's attack. All parties, Catholics and Puritans, as well as the rest of the people, showed a patriotic spirit. A fleet of 180 sail was got ready, commanded by Lord Howard of Effingham, Drake, Frobisher, and Hawkins. Two armies were raised, numbering over 60,000 men. The Spanish armada sailed May 29, 1588, but a storm compelled it to return; and it was not until July 21 that the two fleets met, and joined battle near the English coast. After a series of actions that lasted 18 days the Spaniards were utterly routed, the elements greatly assisting the English. Elizabeth herself is said to have originated the plan of sending fire ships into the Spanish fleet, to which much of the success of the English was owing. The country was thus delivered from present fear of invasion. Leicester died in 1588, after a quarrel with the queen, who had been persuaded by her ministers not to raise him to the post of lord lieutenant of England and Ireland. In 1589, an expedition was sent to effect the liberation of Portugal; but though the army was landed and marched to the suburbs of Lisbon, the undertaking signally failed. Aid in men and money was sent to Henry IV. of France, then contending with Spain and the league, in 1590-'91. A parliament met in 1593, and the commons after some contention with

her submitted to the sovereign. The decision of Henry IV. to abandon the Protestant faith annoyed Elizabeth, and she sought to influence his mind to remain firm, but ineffectually. A plot to poison her was detected, and her Jew physician, Lopez, who had been in her service 34 years, was executed for his part in it. Religious persecutions were now common, and several noted Puritans were put to death. The war with Spain was carried on with vigor, and Cadiz was taken in 1596, by a fleet and army commanded by Howard of Effingham and Essex. The latter was now the principal person in England for a subject, but the infirmities of his temper prevented him from profiting fully from his position and the queen's regard. The court was full of intrigues, and Essex, the most generous and imprudent of men, was the victim of all who chose to play upon him. Philip II. having formed a plan to place his daughter on the English throne, Essex was sent to assail the Spaniards at home and on the ocean. He accomplished nothing, which offended the queen; but he soon recovered her favor, and was enabled to beard Burleigh, until the latter discovered that he was in correspondence with the king of Scotland. Henry IV. having resolved upon peace with Spain, to the anger of Elizabeth, offered to mediate a general peace. Burleigh favored this, and Essex took the other side. It was in a consultation on Irish affairs, in the royal closet, that Essex turned his back contemptuously on the queen, who immediately struck him on the head, and told him to "go and be hanged!" After a display of rashness and temper the earl left the presence. While efforts for a reconciliation were making, Burleigh died, Aug. 4, 1598. Six weeks later died Philip II. Essex returned to court, and shortly after was appointed lord deputy of Ireland, which was in a miserable state. The office was given less in love than in anger, and was the gift of enemies. A politician rather than a statesman, and a knight rather than a soldier, Essex failed entirely in Ireland, whence he returned without permission and entered upon that strange course of action that ended in his death on the scaffold, in 1601. The famous story of the ring and the countess of Nottingham has no foundation in truth; nor is it true that the gloom in which the queen's last days were passed was owing to Essex's death. Sir Robert Cecil, a son of Burleigh, was now Elizabeth's most powerful minister, and he was in correspondence with the king of Scotland. The queen sought to have Henry IV. visit her at Dover, he being at Calais, but he contented himself with sending M. de Rosny, later the duke de Sully, as his ambassador. Their interviews were interesting, and in the first she spoke of the king of Scotland as her successor, who, she said, would be king of Great Britain. This title originated with her. Another embassy was sent to England by Henry, and was well received. Elizabeth's last parliament met in Oct. 1601. It made great opposition to the oppressive monopolies she had

granted, and she gracefully gave way. In the early part of 1603 (N. S.) she suffered from a complication of complaints, but the immediate cause of her death, which took place at Richmond, was a cold. She was buried April 28. Her reign is justly considered one of the most important England has known, and her memory is held in deserved reverence by all classes of Englishmen, and in esteem by the world; for, in despite of many faults of character and errors of conduct, she was a great sovereign. "The Elizabethan age" is one of the most brilliant periods of English history, and the numerous statesmen, soldiers, scholars, and other intellectual personages who then existed, achieved for it a place in the world's annals that has never been surpassed. Of this glory the sovereign has had allowed her far more than her due share, because of the loftiness of her position and the consequences of her actions.

ELIZABETH OF FRANCE, PHILIPPINE MARIE HÉLÈNE, madame, sister of King Louis XVI., born in Versailles, May 8, 1764, guillotined in Paris, May 10, 1794. She early distinguished herself by charity and a taste for serious pursuits, especially botany. When the revolution broke out, she shared her brother's trials and misfortunes, evincing in all circumstances unfaltering firmness, courage, and sweetness of temper. On Oct. 5, 1789, she succeeded in preserving the lives of several of the royal body guard, threatened by the infuriated mob; in June, 1791, she accompanied her brother to Varennes, and sustained his spirit in their dangerous journey back to Paris; on June 20, 1792, when the populace broke into the Tuileries, her life was in danger from being mistaken for the queen; and in all the perils of that period she retained her wonted composure, and thought only of the safety of her brother and his family. She was incarcerated with them in the temple, but was separated from the king on his trial before the convention, and afterward from the queen and the dauphin; and finally, although nothing could be adduced against her except her devotion to her brother, was sentenced to death by the revolutionary tribunal. She met her fate with the patience and intrepidity which had marked all her life.

ELIZABETH OF HUNGARY, saint, countess of Thuringia, daughter of Andrew II., king of Hungary, born in Presburg in 1207, died in Marburg, Germany, Nov. 19, 1231. At 4 years of age she was betrothed to Louis, the eldest son of Hermann, landgrave of Thuringia, and according to the custom of the age was transferred to the household of her future husband, to be educated for her expected rank. The nuptials were celebrated when she had reached her 14th year; and continuing the religious practices for which she had early been remarkable, she enlisted the aid of her husband in the charitable works which engrossed her time. Louis joined the 6th crusade, but died before reaching the Holy Land, and his death at once changed the circumstances of the countess. Her infant son, Hermann, was

declared incapable of succeeding to his father's rule; a party was organized in behalf of Henry, brother of the late count; the castle was seized, and Elizabeth with her 3 children was turned out of her home without provision, money, or a change of raiment. After living some time in great destitution, subsisting now by charity and now by spinning, she was sheltered by her aunt the abbess of Kitzingen, until a more suitable asylum was found in a castle offered for her use by her uncle the bishop of Bamberg. Afterward, at the intercession of the friends of the deceased count, Henry recalled her to Wartburg, and acknowledged the rights of her son; but frequent misunderstandings and difference of tastes led her to petition the count for a separate residence, where she might follow a monastic life, and give herself wholly to works of charity. She took up her abode at Marburg in Hesse, where she spent the remaining 3 years of her life in seclusion. She wore beneath her garment the haircloth of St. Francis, bound herself to obey the orders of her confessor, dismissed her favorite maids when she found herself loving them too well, devoted her liberal allowance entirely to the poor, and supported herself by spinning; she ministered to the most loathsome diseases, and even received lepers into her house. Her confessor, Conrad the legate, exercised his functions with the utmost severity; and in compliance with her own wishes, subjected her to unusual and cruel penances. She was buried with great pomp in the chapel near the hospital which she had founded in Marburg, and the report of the frequent miracles wrought at her tomb induced Gregory IX. in 1235 to add her name to the list of saints. Her shrine was for ages one of the most famous of Europe, rivalling those of St. Thomas of Canterbury and St. James of Compostella. The altar steps before it are worn hollow by the knees of pilgrims, and the name of St. Elizabeth of Hungary still remains throughout Germany the synonyme of all that is sweet, tender, and heroic in Christian faith. Her life has been written by many authors, Catholic and Protestant, in many languages. No fewer than 88 published works and 18 MSS. relating her story are catalogued by Count de Montalembert, whose elaborate and enthusiastic biography is accessible to American readers in the translation by Mary Hackett, published in New York in 1854. The best Protestant life of Saint Elizabeth is that of K. W. Gusti, an edition of which was published in Germany in 1885.

ELIZABETH OF VALOIS, or ISABELLA, queen of Spain, born at Fontainebleau, April 18, 1545, died in Madrid, Oct. 3, 1568. She was a daughter of Henry II. and Catharine de' Medici. By the treaty of Angers (July 19, 1551) she was betrothed to Edward VI. of England, but the marriage was prevented by his premature death. By the preliminaries of the treaty of peace of Cateau Cambrésis, her hand was assigned to Don Carlos, infante of Spain. The treaty was ratified, April 8, 1559; but the

father of Don Carlos, Philip II., being left a widower by the death of his wife, Queen Mary of England, and fascinated by a portrait which he had seen of the French princess, substituted himself for his son. She was united to Philip, Feb. 2, 1560, the marriage ceremony being performed with great splendor at Toledo. She was idolized by the people of Spain, and French as well as Spanish biographers are unanimous in praising her beauty, accomplishments, and virtues. Just before her death she was delivered of a daughter, who lived only to be baptized, and was buried in the same coffin with the mother. Glowing accounts have been given of the relations between Elizabeth and Carlos, but Mr. Prescott in his "History of the Reign of Philip II." proves their groundlessness. Elizabeth took a lively interest in Carlos, and was deeply affected by his tragic end; but, according to Mr. Prescott, her feelings for him were only those of kindness.

ELIZABETH CHARLOTTE, duchess of Orleans, born in Heidelberg, May 27, 1652, died at St. Cloud, Dec. 8, 1722. She was a daughter of the elector Charles Louis of the Palatinate, and so homely that a duke of Courland, who had been betrothed to her, refused to marry her. After embracing Catholicism she became the 2d wife (Nov. 16, 1671) of Philip I., duke of Orleans, brother of Louis XIV. At the French court she became distinguished for her integrity and intellect, as well as for her bluntness and eccentricity. She had a cordial hatred for Madame de Maintenon, and opposed the marriage of her son (the future regent) with Mlle. de Blois, the king's natural daughter. St. Simon gives an amusing account of the energetic manner in which she displayed her feelings on the occasion, by slapping her son in the face in the presence of the whole court. She often attended Louis XIV. to the chase, and the king enjoyed her wit and originality and esteemed her truthful character. Her predilection for the German language and literature increased the intercourse of French with German scholars, especially with Leibnitz, one of her special favorites. Her claims to the Palatinate, however, proved disastrous for Germany, by resulting in the devastation of that country by the armies of Louis XIV. (1688-'93). She wrote various memoirs, which have been several times translated and published in France. Her posthumous letters were also translated from the German, and published by M. G. Brunet in 1853, under the title of *Lettres inédites de la princesse palatine*.

ELIZABETH CHRISTINA, queen of Prussia, born in Brunswick, Nov. 8, 1715, died Jan. 13, 1797. She was a princess of Brunswick-Bevern, a niece of the empress of Germany, and was betrothed to the future Frederic the Great, March 10, 1732. Carlyle, in his history of Frederic (London, 1859), describes her as being at that time "an insipid, fine-complexioned young lady;" and Frederic, who was compelled to marry her by his father, and who was much opposed to the match, said of her in his letters,

to Gen. Grumkow: "She is not at all beautiful, speaks almost nothing, and is given to pouting." The marriage ceremony, however, was performed at Potsdam, June 12, 1733; and Carlyle says that, "with the gay temper of 18 and her native loyalty of mind, she seems to have shaped herself successively to the prince's taste, and growing yearly gracefuller and better-looking, was an ornament and pleasant addition to his existence." Frederic made generous provision for her, and remarked in his will: "During my whole reign she has never given me the slightest cause of dissatisfaction, and her high moral character must inspire respect and love." She was a lady of considerable attainments, wrote several works, and distributed half of her income among the poor.

ELIZABETH CITY, a S. E. co. of Virginia, bordering on Chesapeake bay at the mouth of James river, bounded S. by Hampton Roads, and N. by Back river; area, 50 sq. m.; pop. in 1850, 4,586, of whom 2,148 were slaves. It has a fertile soil, suitable for grain and potatoes. In 1850 it produced 87,295 bushels of Indian corn, 22,188 of wheat, 17,754 of oats, and 42,579 of potatoes. There were 3 flour and grist mills, 7 churches, and 249 pupils attending public schools and academies. This was one of the 8 original shires into which Virginia was divided in 1634. Capital, Hampton. Value of real estate in 1850, \$694,516; in 1856, \$974,946, showing an increase of 40 per cent.

ELIZABETH CITY, a post town and capital of Pasquotank co., N. C., on Pasquotank river, 20 m. from its mouth; pop. in 1850 estimated at 2,000. It is one of the principal towns in the N. E. part of the state. It has communication with Norfolk, Va., by means of the river and the Dismal Swamp canal, and exports lumber and various products of the pitch pine.

ELIZABETH FARNESE, queen of Spain, born Oct. 25, 1692, died in 1766. She was a daughter of Odoardo II., prince of Parma, and of the duchess Sophia Dorothea of Bavaria-Neuburg. Her ungainly appearance and headstrong disposition alienated from her the affections of her mother, and her education was neglected; but those who proposed her as a consort to Philip V. in the hope of making her their tool were greatly disappointed. The king of Spain on becoming a widower in 1714 resigned himself to the guidance of the French princess Des Ursins, the favorite of his late beloved queen, and desired to follow her advice in the choice of a second wife. The princess selected Elizabeth on account of her apparent disqualification for an exalted position. But the first act of the new queen was to cause the dismissal of the princess, and she soon gained a complete mastery over her weak-minded husband and over the affairs of Spain. By her ambition and intrigues, and the great schemes of her minister, Cardinal Alberoni, Europe was thrown into confusion. Spain again obtained possession of the Two Sicilies and of Parma and Piacenza. Carlyle, in his "History of Frederic the Great,"

gives a full description of her quarrels with the emperor Charles VI., and characterizes her as "a termagant, tenacious woman, whose ambitious cupidities were not inferior in obstinacy to Kaiser Karl's, and proved not quite so shadowy as his."

ELIZABETH PETROVNA, empress of Russia, daughter of Peter the Great and Catharine I., born in 1709, died Jan. 9, 1762. After the death of her parents, her nephew, Peter II. (1727-'30), son of the unhappy prince Alexis and her cousin Anna Ivanovna (1730-'40), daughter of the elder brother of Peter the Great, successively occupied the throne of Russia, for which she showed little desire, the pleasures of love, as she used to say, being her supreme good. Anna appointed Ivan, son of Anthony Ulric, duke of Brunswick, a child but a few months old, heir to the crown under the tutelage of his mother Anna, and the regency of Biron, the favorite of the empress. Thus Elizabeth was for a third time excluded from the throne of her father, but even her freedom was now menaced by the jealousy of the mother of the infant czar, who wished to get rid both of the regent and the princess, and advised the latter to take the veil. Under these circumstances her surgeon and favorite, Lestocq, brought about a conspiracy, which being seconded by the favor of the national Russian party, and the intrigues of the ambassador of Louis XV., terminated in a military insurrection, the overthrow of Anna and Ivan, and the proclamation of Elizabeth as empress (Dec. 1741). Anna and her husband, as well as numerous other victims, were punished by confinement, and the young prince imprisoned in the fortress of Schlüsselburg, which he never again left; while the successive favorites of Elizabeth, like herself destitute of character and talent, ruled the court and Russia. Her vanity equalled her gross sensuality; but though sometimes exceedingly cruel and barbarous, she often showed humanity, and even generosity. Subsequently some abler Russians obtained the management of affairs, among them Romanzoff, Bestoujeff, and Woronzoff. Peter, son of her deceased elder sister Anna, duchess of Holstein-Gottorp, was appointed heir to the throne. A war with Sweden was happily conducted, and terminated in the peace of Abo (1743). A plot against her was detected and punished. An army sent to assist the empress Maria Theresa against Frederic the Great contributed to the conclusion of the peace of Aix la Chapelle (1748). Having been cruelly mortified by a sarcasm of the witty Prussian king, Elizabeth allied herself against him with Austria and France in the 7 years' war, and her armies, under Apraxin, Fermor, Soltikoff, and Buturlin, contributed not a little to the distresses of the almost isolated Prussian monarch. They won the battles of Gross Jägerndorf and Kunersdorf, took Colberg, and even occupied Berlin. The death of the empress not only freed Frederic from a dangerous enemy, but also promised to give him in her successor, Peter III.,

an ardent supporter. The licentious disorder in her court lasted till her death. Razumoffski, successively her servant, chamberlain, and field marshal, finally became her secret husband, and is regarded as the father of 3 of her children. The foundation of the university of Moscow, and of the academy of fine arts at St. Petersburg, is one of her greatest merits.

ELIZABETH STUART, queen of Bohemia, born in the palace of Falkland, near Edinburgh, Aug. 16, 1596, died at Leicester House, London, Feb. 13, 1662. She was a daughter of James I. of England, and a highly accomplished princess. She had many suitors, among whom the most eminent were the young king of Spain, Philip III., Charles Emanuel I., prince of Piedmont, and Frederic, elector palatine; but as a Protestant Frederic was preferred. The marriage was celebrated with great pomp in Whitehall chapel, Feb. 14, 1613. To defray part of the expense of the ceremonies the king levied new taxes to the extent of £20,500. The total expense amounted to about £53,000, exclusive of the bride's portion of £40,000. Her husband was the head of the Protestant interest in Germany, and when in 1619 the crown of Bohemia was tendered to him, she urged his acceptance of it, with the remark that he should not have married a king's daughter if he had not the courage to become himself a king. Her entrance into Prague and her coronation were magnificent pageants, but her sovereignty soon came to an end. The imperialist forces advanced into Frederic's hereditary dominions, and into Bohemia, and after the battle of Prague (Nov. 8, 1620) he and his queen were compelled to flee. A refuge was offered to them by the prince of Orange, at the Hague, where most of her children were born. One of her sons was the prince Rupert, so well known in the history of the English civil wars. Her youngest child, Sophia, afterward electress of Hanover, and ancestress of the present English royal family, was born in 1630, shortly after the birth of her nephew, Charles II. Shortly before her death Elizabeth resided for about 6 months in the house of Lord Craven, whose acquaintance she made after the death of her husband (1632), and with whom she lived on terms of the greatest intimacy. Her charms are celebrated by Sir Henry Wotton, in his famous lines beginning: "You meaner beauties of the night."

ELK, a N. W. co. of Penn., traversed by Clarion river, its branches, and some other small streams; area, about 800 sq. m.; pop. in 1850, 3,531. The surface is broken by many hills and rough mountain peaks, the principal of which is Elk mountain, in the southern part. The county is occupied chiefly by thick forests, and lumber is the most important article of export. Bituminous coal is found in great abundance. The soil is better adapted to grazing than to the culture of grain; in 1850 it produced 10,776 bushels of Indian corn, 24,040 of oats, 26,656 tons of hay, and 81,755 lbs. of butter. There were 3 churches, 1 newspaper

office, and 415 pupils attending public schools. The county was organized in 1843, and named from Elk mountain. Capital, Ridgeway.

ELK, a name properly applied to the alpine division of the deer of the snowy regions, to the genus *alce* (H. Smith). In this genus the muzzle is very broad, and covered with hair, except a small bare spot in front of the nostrils; the upper lip is 4 inches longer than the lower, and answers for prehensile purposes; the neck is thick and short, and the throat somewhat maned in both sexes; the hair is coarse, thick, and brittle; the hind legs have the tuft of hair rather above the middle of the metatarsus; the horns in the males are broad and palmated; the tail is short. The nose cavity in the skull is very large, reaching posteriorly to a line over the front of the molars; the long intermaxillaries do not reach to the very short nasals. The horns have no basal snag, the first branch being considerably above the crown. The young are not spotted, but colored like the adult. Elks live in the woods in the northern parts of both continents, but the American is by some considered a distinct species from the European. The true American elk, or moose (as it is universally called here), *alce Americanus* (Jardine), exceeds all other existing deer in size and strength, and unites to great speed remarkable powers of endurance; it is as large as a horse, standing 5 feet high at the shoulders, and measuring about 7 feet from nose to tail; the length of the latter is about a foot; the weight of the horns varies from 45 to 70 lbs., and that of the animal from 8 to 12 cwt. The moose is an awkward, clumsy, and disproportioned creature, though from its size it possesses a certain majesty when seen amid the wild scenery of its favorite haunts. The head is too large in proportion to the body for any pretension to the symmetry usually seen in the deer family; the long, tumid, and movable upper lip gives to the face somewhat of an equine expression, and the heavy ears, more than a foot long, are decidedly asinine. Audubon says: "The head forcibly reminds us of that of an enormous jackass." The eyes are deep-seated and comparatively small; under the throat there is in both sexes a tuft of coarse bristly hair attached to a pendulous gland, which is most conspicuous in the young. The horns are found in the males only, and require 5 years for their full development; they begin to sprout in April, and complete their growth in July; the 1st year they are about an inch long; the 2d year, 4 or 5 inches, with perhaps a rudimentary point; the 3d year, about 9 inches, each dividing into a round fork; in the 4th year they become palmated, with a brow antler and 3 or 4 points; and the 5th year they have 2 crown antlers and 4 or 5 points; after this one or two points are added annually, up to as many as 23, with an expanse sometimes of nearly 6 feet to the outside of the tips, with the palm a foot wide within the points, and a circumference above the burr of 9 inches. The horns diminish in size after the animal has

passed the period of greatest vigor; in old and vigorous animals they are shed in December, but young animals sometimes carry them until March. The 1st inner branch begins about 9 inches from the base; the palms are often unlike on the right and left sides, and are channelled irregularly on both surfaces; their color is brownish yellow, with the ends yellowish white. The incisor teeth, 6 in the lower jaw only, are gouge-like and very white; the eyes are black; the nose, forehead, and upper lip yellowish fawn; the sides of the head yellowish brown; the general color above varies from blackish to ashy gray; below lighter, with a yellowish white tinge. In winter the color is darker, and in advanced age so dark as to merit the name given to it by H. Smith, "the American black elk;" the grayish are said to be the largest, reaching a height of 7 or 8 feet. In summer the hair is short and soft, in winter longer and very coarse, with a fine short wool next the skin. Moose are not uncommon in the northern parts of Maine, and in Canada, Nova Scotia, and Labrador, especially in winter. In summer they frequent lakes and rivers to free themselves from insect pests, and feed upon water plants and the tender branches of overhanging trees. In the winter they retire to the elevated ridges abundantly provided with maple and other hard-wood trees, on the twigs and bark of which they feed. By the elongated upper lip they pull down the branches, which they hold with their fore legs until they are stripped of the twigs; the bark they peel off by including it between the hard pad on the roof of the mouth and the lower incisors. In winter they tread down the snow, forming what are called "yards," in which are generally found a male, female, and 2 fawns; as the trees are stripped they tread down fresh snow, and they are fond of going always in the same tracks. They prefer the twigs of the maple, willow, buttonwood, birch, and aspen, and grasses; in captivity they will eat the food of domestic cattle. Though their flesh is coarse, it is esteemed by hunters; the nose or muffle is a special favorite, being rich, gelatinous, and juicy, when cooked like calf's head; the steaks are juicy, often tender, but seldom fat; the flesh of yearlings is always preferred; the tongue is much relished, as are the fatty appendages to the large intestines, by the keen appetites of the hunters, who also consider the marrow warm from the shank bones an excellent substitute for butter on their bread. The moose trots, runs, and jumps with great speed, passing through seemingly impenetrable thickets and over broken ground without apparent effort; it swims well, with only the head and part of the neck above water; it is never seen like the reindeer on the ice, except from absolute necessity; when walking on untrodden snow its feet generally sink into it to the ground. Its sense of smell is very acute, and enables it to detect an enemy at a great distance; the breaking of the smallest twig is sufficient to startle it from its hiding place. The

pairing season begins in September; during October the males become furious, fighting each other whenever they meet; they run noisily through the woods, and swim lakes and rivers in pursuit of the female; at this time it is dangerous for the hunter to approach, as they do not hesitate to attack him. The young are born in May, the first time one, and 2 annually afterward; the females are also very fierce in defence of their calves. The males are called bulls and the females cows. The proper times for hunting the moose are in March and September; in the latter month the animals are in their prime, and in the former they are most easily taken on account of the sharp crust impeding their progress through the snow. In hunting them in March, a few small curs are useful in worrying the animal and delaying him until the hunter comes up; it is useless to pursue them through soft snow, which offers no impediment unless it be deep, when the hunter can easily overtake them on snow-shoes. Many are shot from canoes on moonlight nights in September; the hunter imitates the call of the male, which, angry at the supposed intrusion of a rival, rushes to the water's edge to fight him, and meets instead the fatal bullet of his concealed foe. Slip-nooses attached to strong saplings, bent down in the moose paths to the water, will occasionally entrap a victim. The most exciting and most successful way is to start them from their yards, and pursue them over the snow. When wounded and brought to bay, they defend themselves fiercely, striking with their fore feet and horns; they will frequently turn upon the hunter when not wounded, and force him to fly for his life. Moose have been domesticated, and taught to draw carts and sledges, but during the rutting season they become perfectly intractable; if necessary, they might perhaps be made as useful to semi-civilized man as the reindeer. Their geographical distribution is extensive; they have been found at the mouths of the Mackenzie and Coppermine rivers, on the eastern slope of the Rocky mountains at the sources of Elk river, and in Oregon; on the eastern coast they are found from Labrador to northern New England and New York, their southern limit seeming to be 43° 30'. As in all other deer of cold and mountainous regions, there is considerable diversity in the size of the body and the horns of the moose, according to the abundance of food in the places inhabited by them.—The European elk (*A. malchis*, Ogilby) was once found between the 53d and 65th degrees of latitude, in Prussia, Poland, Sweden, Norway, and Russia, but is rarely seen at present except in the most northern of these countries; in Asiatic Siberia it is also found. The appearance is the same as that of the moose; from its long legs and overhanging lips the old authors thought that it grazed walking backward. From the great height of the shoulders above the crupper its gait is awkward and shuffling, and when running fast the hind limbs are very wide apart; its joints crack at every

step, with a sound which may be heard at a considerable distance; a part of the sound is said to be made by the hoofs striking against each other. According to Hamilton Smith, the Teutonic name *elend* (miserable) was applied to this animal from its supposed frequent attacks of epilepsy, while its falls are really attributable to its tripping itself up by treading on its fore heels, the elevated position of the nose, with the horns laid horizontally on the back, preventing it from seeing the ground distinctly before it. The European elk seems to attain a size equal to that of the moose, measuring 6 feet high at the shoulder. The period of life is said to be about 20 years. Pennant states that elks were once used to draw sledges in Sweden, and that they could travel over 200 miles a day; their hide makes excellent leather for belts and coverings for the feet. Though most authors have regarded the American and European elks as the same, Agassiz has described the former as distinct, with the specific name *lobatus*, from differences in the shape of the nose, the form and branching of the horns, and other points. Sir John Richardson (in the "Fossil Mammals" of the "Zoology of H. M. S. Herald") also considers the species distinct, calling the American *A. muswa*; he compares the skeletons carefully, and mentions, among other characters, that the breadth of the face at the most protuberant part of the maxillary bones is less in the American than in the European elk; if they be regarded as the same, the proper name would be *A. Americanus* (Jardine). The name of elk is applied in this country to the wapiti (*ceruus Canadensis*, Briss.), which should be called the American stag; this name is also given by the British sportsmen in India to some of the rusa or samboo deer; so that it is necessary to consider the country of the animal before deciding on the meaning of the word "elk."—There are many fossil species called elks, as the fossil or Irish elk (*C. giganteus*, Cuv.), found in the diluvial strata of Europe, and especially in the peat bogs of Ireland; this species was of great size, with an enormous development of horns, which, resembling those of the elk in their broad palmations, differed in the size and low situation of the basal antlers; in other parts of the skeleton it resembled most the stags. Another species, found in the peat bogs and upper tertiary of France and Germany, seems to have been a gigantic fallow deer. The fossil elk described by H. de Meyer, from the diluvium of Europe, differed from the living animal in the form of its forehead. A fossil elk (*C. Americanus*), allied to the wapiti, has been found in the United States, with the bones of the mastodon. The fossil *sivatherium*, described by Cautley and Falconer, from the Sewalik hills of the lower Himalaya range, seems in many respects to have resembled the moose; the form of the head and its size lead to the belief that it was elephant-like in the cellular prominences of its posterior portion; the face was short, and the nasal bones were raised into an arch over the external nostrils, indicating the pro-

existence of a trunk; we see the upper lip of the moose elongated also into a kind of prehensile proboscis; the head was also armed with 2 spreading horns, arising above and between the orbits; the molar teeth are entirely like those of ruminants; the anterior extremities (of which casts exist in the cabinet of the Boston society of natural history) indicate an animal of the size of a large elephant. This animal was undoubtedly a ruminant, with the pachyderm characters of a heavy form, short neck, and probably a proboscis; in like manner the ruminant moose departs from the deer family, and approaches the pachyderms (especially the *equidae*) in its movable elongated snout, long ears, and general shape of the head and body.

ELKHART, a N. co. of Ind., bordering on Mich., and watered by St. Joseph's and Elkhart rivers, which unite within its borders; area, 467 sq. m.; pop. in 1850, 12,690. The surface is moderately uneven and diversified by prairies, oak openings, and several small lakes. The soil is fertile, and the productions in 1850 were 370,973 bushels of Indian corn, 174,716 of wheat, 104,940 of oats, and 8,287 tons of hay. There were 10 churches, 1 newspaper office, and 1,800 pupils attending public schools. The county has communication with Toledo, Chicago, and other places, by the Michigan southern and northern Indiana railroad, which passes through Goshen, the capital.—ELKHART, a post village and township of the above county, at the confluence of the St. Joseph's and Elkhart rivers, 156 m. N. from Indianapolis; pop. of the township in 1850, 1,035. It is the principal entrepot for the exports of the county, being situated on the line of the Michigan southern and northern Indiana railroad, and having communication by means of the river with Lake Michigan.

ELKHORN, the county seat of Walworth co., Wis., 12 m. N. from the Illinois state line, 4 m. W. from Lake Michigan, at the junction of the Racine and Mississippi and Wisconsin central railroads, and on the N. side of the Elkhorn prairie; pop. in 1858, above 1,500. In the same year it had a large and well finished court house, gaol, fire-proof county offices, 4 churches, large railroad buildings, and numerous stores and public houses.

ELL, a measure of length in various countries, used chiefly for cloths, linens, silks, and similar fabrics. The ell English is 45 inches, or 5 quarters; the ell Flemish 27 inches, or 3 quarters; the Scotch ell 37.06 inches.

ELLENBOROUGH, EDWARD LAW, baron, chief justice of the court of king's bench in England, born at Great Salkeld, Cumberland, Nov. 16, 1750, died in London, Dec. 13, 1818. He was educated at the Charterhouse school in London, and at St. Peter's college, Cambridge, and upon being called to the bar soon became eminent in his profession. His abilities as a lawyer and speaker were first displayed to advantage in the trial of Warren Hastings in 1788-'95, in which as leading counsel for the defendant he coped successfully with the eminent lawyers and states-

men opposed to him. In 1801 he was appointed attorney-general, and in 1802 he succeeded Lord Kenyon as chief justice of the king's bench, on which occasion he was elevated to the peerage as Baron Ellenborough. He retired from the bench a few weeks previous to his death.—EDWARD LAW, 1st earl of, an English statesman, son of the preceding, born Sept. 8, 1790. He was educated at Eton and at St. John's college, Cambridge, where he was graduated in 1809. Shortly afterward he entered parliament as a member for the now disfranchised borough of St. Michael's. Being a firm advocate of tory principles and a fluent speaker, upon the accession of the duke of Wellington to office, in 1828, he was appointed lord privy seal. During the administration of Sir Robert Peel, in 1834-'5, he became president of the board of control and first commissioner of Indian affairs, an office to which he was reappointed in Sept. 1841, upon the conservative triumph of that year. A few weeks afterward he was appointed to succeed Lord Auckland as governor-general of India. He arrived in Calcutta in Feb. 1842, and in April, 1844, he was recalled by the board of East India directors, contrary to the wishes of the cabinet. During his administration Scinde was annexed to the British dominions, and Gwalior reduced to subjection; but he was charged with excessive tenderness for the native troops, to the neglect of the employees in the civil service; with issuing proclamations which seemed to sanction idolatry; and with other questionable acts in his official capacity. Upon his return to England, however, he was created an earl, and in 1846 was appointed first lord of the admiralty, which office he held for a few months only. He remained out of office until the formation of the Derby cabinet in Feb. 1858, when he again became president of the board of control. In the succeeding May a despatch from Lord Ellenborough to Lord Canning, governor-general of India, strongly condemnatory of the proclamation of the latter confiscating the property of the natives of Oude, was made public, and excited such animadversion, that on the 11th of the month, after vindicating his course in a speech in the house of lords, he announced that rather than expose his colleagues to the censure of parliament he had resigned his office. The earl of Derby said that the resignation had been accepted with regret, but admitted that he considered the publication of the despatch premature and injudicious.

ELLERY, WILLIAM, one of the signers of the American declaration of independence, born in Newport, R. I., Dec. 23, 1727, died there, Feb. 15, 1820. He was graduated at Harvard college in 1747, and for a number of years after his marriage, which took place in 1750, was engaged in mercantile pursuits in Newport. He was also for some time naval officer of the colony of Rhode Island. In 1770, having for 2 years previous served as clerk of one of the courts, he commenced the practice of the law

in Newport, in which he acquired eminence. The era of the revolution found him an ardent sympathizer with the colonies in their struggle with the mother country, and in May, 1776, he entered active political life by taking his seat in the memorable congress of that year as one of the delegates from Rhode Island. With his colleague, Stephen Hopkins, he set his name to the declaration of independence, the incidents connected with which event he was accustomed in his latter years to relate with great vivacity. He remained in congress until 1786, with the exception of the years 1780 and 1782, and on all occasions proved himself an active and useful member, and, notwithstanding a natural diffidence which it required strong efforts to overcome, a ready debater. As a member of the marine committee, and subsequently of the board of admiralty, he exercised considerable influence during his whole term of service, and the plan of fire ships to be fitted out at Newport has been attributed to him. In April, 1786, he was elected by congress commissioner of the continental loan office for the state of Rhode Island, and in 1790 was appointed by President Washington collector of Newport, an office which he held until his death, notwithstanding his frequent and frank avowals of political principles directly opposed to those of several administrations. He retained full possession of his mental faculties until the close of his long life, and was highly esteemed in his native place, not less for his social qualities and intellectual abilities than as a relic of the revolutionary era. An interesting biography of him by his grandson, Professor Edward T. Channing, is published in Sparks's "American Biography," vol. vi.

ELLESMERE, FRANCIS EGERTON, earl of, an English nobleman, born in London, Jan. 1, 1800, died there, Feb. 18, 1857. He was the 2d son of the 1st duke of Sutherland, and until the death of his father was known as Lord Francis Leveson-Gower. He was educated at Eton, and at Christchurch, Oxford, where he was graduated in 1821. In the succeeding year he entered parliament as a liberal conservative and a supporter of Canning, and became one of the earliest and most earnest advocates of free trade. He also supported the project for establishing the university of London, and on one occasion carried a motion through the house of commons for the endowment of the Roman Catholic clergy of Ireland. Between 1827 and 1830 he held various political offices; but in the latter year he retired from parliament. In 1833, upon the decease of his father, he came into possession of the immense estates of the late duke of Bridgewater, and of the picture gallery, valued at £150,000, which had been bequeathed to the duke of Sutherland, with reversion to his 2d son; on which occasion he assumed the name of Egerton in the place of his patronymic of Leveson-Gower. In 1835 he was elected member of parliament for South Lancashire, and continued to represent that constituency until 1846, when he was

raised to the peerage as earl of Ellesmere, after which he retired from active political life. While a student at the university he printed a volume of poems for private circulation; but his first public appearance as an author was in 1824, when he published a translation of "Faust," with versions of popular lyrics from the works of Goethe, Schiller, and other German poets. He subsequently produced "Mediterranean Sketches" (London, 1843), containing the "Pilgrimage," a poem which records the author's tour in Palestine; "The two Sieges of Vienna by the Turks" (1847); "Guide to Northern Archæology" (1848); and a number of poems and plays printed for private circulation. The "Pilgrimage," after having been withheld from general circulation for many years, was republished in 1856 with a number of additional poems. In 1853 Lord Ellesmere visited the United States as British commissioner to the American exhibition of industry in New York, returning to England the same year.

ELLET, WILLIAM HENRY, an American chemist, born in New York about 1804, died in that city, Jan. 26, 1859. He was graduated at Columbia college in 1824. While pursuing his medical studies he gained a gold medal for a dissertation on the compounds of cyanogen. In 1832 he was elected professor of experimental chemistry in Columbia college, a position which he resigned in 1835 to become professor of chemistry, mineralogy, and geology in the South Carolina college. In 1848 he returned to New York, where he resided until his death. The legislature of South Carolina presented him with a service of silver plate for the discovery of a new and cheap method of preparing gun cotton. During the last 5 years of his life he was consulting chemist of the Manhattan gas company of New York.—ELIZABETH FRIES LUMMIS, wife of the preceding, an American authoress, born at Sodus Point, on Lake Ontario, N. Y. She is the daughter of Dr. William N. Lummis, a physician of some eminence, and at an early age was married to Professor Ellet, whom she accompanied to South Carolina, and with whom she returned to New York in 1848. In 1835 she produced a volume of poems, beside which she published while in South Carolina "Scenes in the Life of Joanna of Sicily" (12mo., 1840), "Characters of Schiller" (1841), and "Country Rambles," and contributed articles to several quarterly reviews on French and Italian poetry and literature. In 1848 she published, in 3 vols. 12mo., the "Women of the American Revolution," one of her most popular works, and the materials for which were derived from original sources. Subsequently appeared her "Evenings at Woodlawn," "Family Pictures from the Bible" (1849), "Domestic History of the American Revolution" (1850), "Watching Spirits" (1851), "Pioneer Women of the West" (1852), "Novellettes of the Musicians" (1852), and "Summer Rambles in the West" (1853). She also edited "The Practical Housekeeper." She is now engaged

upon a dictionary of female painters and sculptors, in which sketches are given of the women artists of all ages and countries.

ELLICOTT, ANDREW, an American astronomer and civil engineer, born in Bucks co., Penn., Jan. 24, 1754, died at West Point, N. Y., Aug. 28, 1820. His father, having united with a brother in the purchase of a large tract of wild land on the Patapsco river in 1770, left Bucks co. in 1774, and became a founder of what is now the town of Ellicott's Mills in Maryland, where the younger days of Mr. Ellicott were devoted to the study of the sciences and practical mechanics. Though belonging to the society of Friends, Mr. Ellicott commanded a battalion of Maryland militia in the revolution. His scientific attainments early attracted public attention, and from the revolution to the day of his death he was employed in the fulfilment of trusts conferred by the general or state governments. He enjoyed the friendship and confidence of Washington and his successors during life, and maintained the most intimate relations with Franklin and Rittenhouse, of whom his papers contain many interesting memorials. At various times he was appointed commissioner for marking parts of the boundaries of Virginia, Pennsylvania, and New York. About 1785 he removed to Baltimore, and represented that city in the state legislature. In 1789 he was appointed by President Washington to survey the land lying between Pennsylvania and Lake Erie, and during that year he made the first accurate measurement of the Niagara river from lake to lake, with the height of the falls and the fall of the rapids. In 1790 he was employed by the government to survey and lay out the federal metropolis. In 1792 he was made surveyor-general of the United States, and in 1795 he superintended the construction of Fort Erie at Presque Isle (now Erie, Penn.), and was employed in laying out the towns of Erie, Warren, and Franklin. In 1796 he was appointed by President Washington commissioner on behalf of the United States under the treaty of San Lorenzo el Real, to determine the southern boundary separating the United States territory from the Spanish possessions. The results of this service, embracing a period of nearly 5 years, appear in his "Journal," published in 4to., with 6 maps (Philadelphia, 1803). Upon the completion of this service he was appointed by Gov. McKean of Pennsylvania secretary of the state land office, the duties of which he performed to the year 1808, and in 1812 he received the post of professor of mathematics at West Point. In 1817, by order of the government, he proceeded to Montreal to make astronomical observations for carrying into effect some of the articles of the treaty of Ghent. He continued to fill the professorship of mathematics and civil engineering to the time of his death. Mr. Ellicott was an active member and useful officer of the American philosophical society, and maintained correspondence with the learned societies of Europe; but with the exception of his "Jour-

nal," contributions to philosophical societies, and a few other writings, his works are yet in manuscript.—JOSEPH, brother of the preceding, born in Pennsylvania, died in Batavia, N. Y., in 1826. In 1790 he assisted his brother Andrew in laying out the city of Washington, and in 1791 was appointed to run the boundary line between Georgia and the Creek Indians; and for a long period, embracing the most active portion of his life, he was engaged in the service of the Holland land company. He was a good mathematician, a scientific surveyor, and an able financier, led a life of great usefulness and enterprise, and was identified with the great public improvements of the state of New York.

ELLICOTT'S MILLS, a post village and township of Howard and Baltimore cos., Md., on the Patapsco river, 10 m. from the city of Baltimore; pop. in 1850, 1,059. It was first settled in 1774 by the brothers Andrew and John Ellicott, whose large flouring mills here at one time held precedence in extent and perfection over all similar manufactories in the country. For many years the whole of Ellicott's Mills, and extended tracts of country on the river, above and below, were kept with studied exclusiveness within the family. In 1859 not one of the name is residing within the limits of the settlement. The water power is excellent, and numerous cotton and other factories are propelled by it. The Baltimore and Ohio railroad passes through the village. It is the seat of St. Charles's (R. C.) college.

ELLIOTSON, JOHN, an English physician and physiologist, born in London in the latter part of the last century. He received his medical education at the university of Edinburgh and at Cambridge, and subsequently attended the medical and surgical practice of St. Thomas's and Guy's hospitals in London, of the latter of which institutions he was in 1822 elected physician. Subsequently he became lecturer on the practice of medicine in St. Thomas's hospital, and in 1831 was appointed professor of the principles and practice of medicine and of clinical medicine in University college, London, in connection with which 3 years later he succeeded in establishing a hospital, when he resigned his professorship at St. Thomas's. As a lecturer he obtained great popularity, not less from his genial manner than from his thorough mastery of his subject. His use of prussic acid in certain complaints, and of other new remedies, however, met with much opposition; and in attempting to reform the old routine of the hospitals, he incurred the hostility of many of the profession. He was the founder and subsequently the president of the phrenological society, and the president of the royal medical and chirurgical society. In 1837 the attention of Dr. Elliotson was drawn to the phenomena of animal magnetism, and to the reputed removal or alleviation of difficult diseases through its agency. Having satisfied himself that much of what he had read and heard upon the subject was founded on fact, he commenced a series of experiments which were

attended by eminent scientific men from all parts of the kingdom, including a number of the medical faculty, and the striking results obtained from which convinced him that animal magnetism or mesmerism afforded a certain remedy for several diseases previously believed to be incurable, and was also the most powerful agent for allaying the pain attending surgical operations. His efforts gained many converts to mesmerism from the educated classes, whose zeal in his behalf was equalled by the violence of the opposition which assailed him. The unwillingness of his medical colleagues and of the council of the university to allow the mesmeric cure to be applied to the hospital patients induced him, in December, 1838, to sever his connection with University college, an event which made a considerable stir in the scientific world, and since that time he has been an indefatigable advocate of the curative agency of animal magnetism. In 1849 he was instrumental in establishing a mesmeric hospital, in which many remarkable cures have been effected. A mesmeric journal, called the "Zoist," was also established by him. Dr. Elliottson's principal contributions to medical science are: "Lectures on Diseases of the Heart" (London, 1830), which were delivered before the royal college of physicians in 1829; a translation of Blumenbach's "Physiology" (1817-'56), the notes to which are more voluminous than the text; the "Principles and Practice of Medicine" (London, 1840), a valuable work, which has been translated into various European languages; "Surgical Operations in the Mesmeric State without Pain" (London, 1843), &c.

ELLIOTT, CHARLES, D.D., an American Methodist divine, born in Killybegs, Donegal, Ireland, May 16, 1792. In his youth he became a member of the Wesleyan Methodist society, soon after began a course of study preparatory for the ministry, and in his 24th year applied to the Dublin university for admission, but was refused because he could not conscientiously submit to the established test. Having obtained, however, with the aid of classical scholars, what was equivalent to a university course, he emigrated to America, and proceeded to Ohio, where he was received into the travelling connection of the Ohio conference in 1818. For the first 4 years he travelled over extensive circuits, and cheerfully submitted to all the privations of pioneer life. In 1822 he was appointed superintendent of the mission among the Wyandot Indians at Upper Sandusky, was subsequently for 5 years presiding elder of the Ohio district, and was then elected professor of languages in Madison college, Uniontown, Penn., where he remained 4 years. In 1831 he was stationed in Pittsburg, and was subsequently presiding elder of that district. While serving in this capacity he was chosen editor of the "Pittsburg Conference Journal," and was afterward transferred to the editorship of the "Western Christian Advocate," at Cincinnati, where he remained until 1848. He again entered the regular work of the clergy, but in the general

conference of 1852 he was reelected editor of the "Western Advocate," which office he filled for another term of 4 years, making in all about 15 years of editorial service. He has also written a "Treatise on Baptism" (1834); "Life of Bishop Roberts;" "Delineation of Roman Catholicism" (2 vols. 8vo., New York, 1851); and "History of the Great Secession from the Methodist Episcopal Church" (8vo., Cincinnati, 1855). Dr. Elliott is now president of the Iowa Wesleyan university, and is preparing a work on "Political Romanism."

ELLIOTT, CHARLES WYLLYS, an American author, born in Guilford, Conn., May 27, 1817. He is the 5th generation in lineal descent from Eliot the "Indian Apostle." After some years spent in mercantile life in the city of New York, he in 1838-'9 studied horticulture and landscape gardening with A. J. Downing at Newburg, and from 1840 to 1848 practised those pursuits at Cincinnati. Since 1850 he has resided in New York. He was one of the founders and first trustees of the "Children's Aid Society" in 1858. In 1857 he was appointed one of the commissioners for laying out the central park in the city of New York. Mr. Elliott has published the following works: "Mysteries, or Glimpses of the Supernatural" (1 vol. 12mo., New York, 1852), an attempt to refute spiritualism; "St. Domingo, its Revolution and its Hero, Toussaint Louverture" (1 vol. 12mo., New York, 1855); "The New England History, from the Discovery of the Continent by the Northmen, A. D. 986, to 1776" (2 vols. 8vo., New York, 1857).

ELLIOTT, CHARLES LORING, an American painter, born in Scipio, N. Y., in 1812. His father, an architect by profession, removed to Syracuse in the childhood of his son, and placed him in the store of a country merchant. The occupation was altogether distasteful to young Elliott, who devoted all his leisure time to his favorite pursuits of drawing and painting, with the expectation of one day becoming a painter. His father, seeing that he was unfitted for a mercantile life, allowed him to study drawing and architecture, though chiefly with the view of making a practical architect of him. Elliott, soon tiring of this occupation, went to New York and became a pupil of Trumbull, and subsequently of Quidor, a painter of fancy pieces, with whom he remained long enough to acquire a knowledge of the technicalities of his art. His chief employment for some time was copying prints in oils, and he afterward attempted portraits, though with no great success. Some of his youthful productions, however, evinced talent, and some oil paintings by him representing scenes from Irving's and Paulding's works attracted considerable attention. After about a year's residence in New York he returned to the western part of the state, where he practised his profession, more particularly portrait painting, for about 10 years. Returning to New York at the end of that period, he established himself there as a portrait painter, and has since

been a resident of that city or its immediate neighborhood. His works consist almost exclusively of portraits, many of which are of eminent American citizens, and are remarkable for the fidelity of the likeness and their vigorous coloring. Since 1846 Mr. Elliott has been a member of the national academy of design.

ELLIOTT, EBENEZER, an English poet, born at Masborough, near Rotherham, Yorkshire, March 17, 1781, died near Barnsley, Dec. 1, 1849. His father, who was employed in a foundery near Masborough, was a dissenter of what was called the Berean sect, an occasional preacher, and a forcible political speaker of the ultra radical type. Young Elliott received the education usually afforded to boys of his condition, but at school was noted for little else than dullness and laziness. He was unable to master the rudiments of grammar or arithmetic, and often gratified an instinctive love for nature and solitude by stolen rambles in the meadows and woodlands. His father, hearing of these vagabond habits, set him to work in the foundery. He was beginning to fall into dissipated habits when the perusal of a treatise on botany, which accident put into his hands, revived his love of nature, and he became an industrious collector of botanical specimens. He also procured access to a small library of the old divines and poets, and in his 17th year produced his first published poem, "The Vernal Walk," a crude imitation of Thomson. It was followed by "Night," "Wharnccliffe," and others. The author's powers increased with each new work, and he had the good fortune to attract the notice of Southey, to whose kind offices he was accustomed to refer with affection and gratitude. He had meanwhile worked steadily at the foundery, which his father had purchased on credit, and having married set up in the iron business on his own account. At 30 years of age he became an earnest advocate of the laboring classes. The corn laws in particular struck him as unjust, and upon his subsequent failure in business he attributed his misfortunes to their influence. In 1821 he made another venture as an iron merchant in Sheffield, with a borrowed capital of £100, and was soon embarked in a lucrative business. He now commenced his well-known "Corn Law Rhymes," which were written with the sole purpose of procuring the repeal of the obnoxious laws. At first published in a local paper and afterward collected in a single volume, these poems brought Elliott into notice. The "Ranter," which succeeded, was a long poem in a similar vein. In 1829 appeared his "Village Patriarch," exceeding in length any of his previous productions, and the best of his larger pieces. In 1833 he commenced a complete edition of his works, which appeared during the next 2 years, and for the first time made generally known many of the author's poems not of an exclusively political character. Several other editions appeared in the course of his life, and to the last he continued to write verses, chiefly for the periodical press, and not unfrequently

spoke in public in support of his peculiar views. The commercial panic of 1837 entailed serious pecuniary losses upon him, but by careful management he was enabled in 1841 to retire from business with a competency and settle at a villa near Barnsley, where he passed the last years of his life in pleasant seclusion. Since his death 2 volumes of his literary remains have appeared under the title of "More Prose and Verse by the Corn Law Rhymer."

ELLIOTT, JESSE DUNCAN, a commodore in the U. S. navy, born in Maryland in 1782, died in Philadelphia, Dec. 18, 1845. He entered the service as a midshipman in April, 1804, and was promoted to a lieutenant in April, 1810. In 1812 he was attached to the command of Commodore Isaac Chauncey at Sackett's Harbor, and was sent by him to the upper lakes to purchase vessels, and make other preparations for the creation of a naval force in those waters. While at Black Rock, engaged in this service, 2 British brigs, the *Detroit* and *Caledonia*, anchored, Oct. 7, 1812, near the opposite shore under the guns of Fort Erie. Elliott conceived the idea of capturing them. Fortunately the first party of seamen intended for the lake service arrived from the seaboard on that very night, and Gen. Smythe, the commanding military officer on the frontier, not only promptly complied with the requisition for arms for this service, but furnished a detachment of 50 soldiers for the purpose. A boat expedition was organized under Elliott's command, and the vessels were boarded and carried with but slight loss a little after midnight, Oct. 8. The *Detroit* mounted 6 guns, with a crew of 56; the *Caledonia* mounted 2 guns, and had a smaller complement. About 40 American prisoners were found on board these vessels. The *Caledonia* was safely brought over to the American side, but the *Detroit* was compelled to drop down the river, passing the British batteries under a heavy fire, and anchoring within reach of their guns. In the end this vessel was burned by the Americans, most of her stores having first been removed. For this exploit Elliott was voted a sword by congress. In July, 1813, he was promoted to the rank of master commandant, and appointed to the *Niagara*, a brig of 20 guns, on Lake Erie. In Perry's memorable engagement with the British squadron, Sept. 10, 1813, Elliott was second in command, and a gold medal was voted him by congress for his conduct on the occasion. After the battle of Lake Erie, Elliott returned to Lake Ontario, where he was actively employed until Nov. 1813, when he was appointed to the command of the Ontario sloop of war, which had just been built at Baltimore. This vessel was one of the squadron of Commodore Decatur employed against Algiers in 1815, and assisted in the capture of an Algerine frigate off Cape de Gatt. In March, 1818, he was promoted to the rank of captain, and subsequently had the command of squadrons on the coast of Brazil, in the West Indies, and in the Mediterranean, and of the navy yards at Boston and Philadelphia. His conduct while

in command of the Mediterranean squadron did not meet the approval of the executive, and resulted in his trial by court martial in June, 1840, and suspension from duty for 4 years. In Oct. 1843, the period of his suspension which then remained was remitted by the president. Commodore Elliott's name was much before the public for many years, as his conduct in the battle of Lake Erie unfortunately became the subject of a controversy which lasted until his death.

ELLIOTT, STEPHEN, an American naturalist, born in Beaufort, S. C., Nov. 11, 1771, died in Charleston, March 28, 1830. He was graduated at Yale college in 1791, and 2 years later was elected a member of the legislature of South Carolina, a position which he retained until the establishment of the "Bank of the State" in 1812, of which he was chosen the president. He retained this office till his death. His leisure hours were devoted to literary and scientific pursuits, and he cultivated the study of botany with enthusiasm. In 1813 he was instrumental in founding the literary and philosophical societies of South Carolina, of each of which he was the president. He lectured gratuitously on his favorite science, and was for some time chief editor of the "Southern Review," to which he contributed a number of articles. In 1825 he aided in establishing the medical college of the state, and was elected one of the faculty, and professor of natural history and botany. He is the author of the "Botany of South Carolina and Georgia" (2 vols. 8vo., Charleston, 1821-'24), in the preparation of which he was assisted by Dr. James McBride, and left a number of works in manuscript. His acquaintance with general literature was extensive, and he was thoroughly read in the scientific works of the modern French school. His collection in the several departments of natural history was at the time of his death one of the most extensive in the country. The degree of LL.D. was conferred upon him by Yale and Harvard colleges.—STEPHEN, D.D., son of the preceding, bishop of the Protestant Episcopal church for the diocese of Georgia, born at Beaufort, S. C., in 1806. He was graduated at Harvard college in 1824, and was ordained a deacon in 1835, and a priest in 1836, soon after which he became professor of sacred literature in the South Carolina college. In 1840 he was elected bishop of Georgia, and in Feb. 1841, was consecrated.

ELLIOTT, WILLIAM, an American author and politician, born in Beaufort, S. C., April 27, 1788. He was entered in Harvard college at the age of 18, but ill health compelled him to return home before the completion of his academical career. For many years he devoted himself to the management of his estates, and served with credit in both branches of the state legislature. During the nullification crisis in South Carolina in 1832 he held the office of senator in the state legislature, but resigned upon being instructed by his constituents to vote to nullify the tariff law. He has since participated less frequently in public affairs, his letters against secession signed

"Agricola," and published in 1851, being among his latest expressions of opinion on political subjects. He has contributed largely to the periodical press of the South. His published works consist of an "Address before the St. Paul's Agricultural Society" (Charleston, 1850), and "Carolina Sports by Land and Water" (1856). He is also the author of "Fiesco," a tragedy printed for the author in 1850, and of a number of occasional poems of merit, few of which, however, have been published.

ELLIPSE, one of the conic sections, a figure bounded by a curve line produced by cutting through a cone with a plane, or by letting the shadow of a circle fall on a plane. The discussion of this curve began with Plato, 480-347 B. C., and was continued with great zeal for about 2 centuries. No important advance in the knowledge of the ellipse was then made for about 1700 years, when the research into its properties was renewed and still continues. The ellipticity of the planetary orbits is one of the immortal discoveries of Kepler. The knowledge of this curve is essential in the mathematical investigation of many physical problems. One of the most important properties of the curve line bounding an ellipse is that every point in this line is at such distances from 2 points in the figure called the foci, that the sum of the 2 distances is always equal to the longest diameter of the ellipse. An ellipse may therefore be drawn by driving 2 pins in a board, to mark the foci, putting a loose loop of inelastic thread over the pins, and then drawing the curve with a pencil placed inside the loop and stretched out as far as the loop will allow. A second important property of the curve is that lines from any point of it drawn to the foci make equal angles with the curve. Hence light emanating from one focus would be reflected by the curve to the other focus. If the other focus were at an immeasurable distance, the curve would be a parabola, and the light would proceed out in parallel lines; or light coming from an inverse distance would be reflected into the focus. Hence the parabola gives the proper form for a telescopic mirror. These are the most important of the simpler properties of the ellipse; the higher and equally important properties are scarcely capable of expression without the use of mathematical forms. When an ellipse, instead of being traced on a plane surface, is traced on the surface of a sphere, it is called a spherical ellipse.

ELLIS, a N. co. of Texas, drained by Trinity river, which forms its E. boundary; area, 1,000 sq. m.; pop. in 1858, 8,212, of whom 723 were slaves. The surface is occupied by prairies and tracts of hard timber. The prairies are very fertile, and produce maize and cotton. In 1850 there were raised here 28,744 bushels of Indian corn, 2,617 of potatoes, 17,220 lbs. of butter and cheese, 287 of rice, and 200 of tobacco. Value of real estate in 1858, \$545,600. Capital, Waxahachie. Formed in 1849.

ELLIS, GEORGE EDWARD, an American clergyman, pastor of the Harvard church, Charles-

town, Mass., born in Boston in 1815. He was graduated at Harvard college in 1833, studied theology at the Cambridge divinity school until 1836, and after a year's travel in Europe was ordained in 1840 as pastor of the church still under his charge, and previously under the charge of the Rev. James Walker, now president of Harvard university. He has been an industrious and successful writer, is the author of the lives of John Mason, Anne Hutchinson, and William Penn, in Sparks's "American Biography," and in 1857 published a very elaborate work, the "Half Century of the Unitarian Controversy." He edited for a time the "Christian Register," the religious newspaper of the Massachusetts Unitarians, and for some years, in connection with the Rev. George Putnam, D.D., he conducted the "Christian Examiner." He has contributed largely to various periodicals, including the "New York Review," the "North American," the "Christian Examiner," and the "Atlantic Monthly," most frequently upon topics of American history. In 1857 he was appointed professor of doctrinal theology in the Cambridge divinity school, and received the degree of D.D. from Harvard university. He is a prominent member of the Massachusetts historical society, and active in its antiquarian researches and collections. In his religious views he belongs to the more conservative class of Unitarians, and takes a decided stand against the new rationalism. He is a zealous friend of popular education, and has spoken and written much for common schools. His published sermons, addresses, pamphlets, &c., have been numerous.

ELLIS, GEORGE, an English author, born in 1745, died April 15, 1815. He commenced his literary career as a writer of political satires, and became favorably known as a contributor to the "Rolliad," and subsequently to the "Anti-Jacobin." The study of early English literature, however, occupied his leisure hours, and in 1780 he produced "Specimens of Ancient English Poetry," of which enlarged editions appeared in 1801 and 1811. A companion work, "Specimens of Ancient English Romances," appeared in 3 vols. 8vo. in 1805, and has since been republished in Bohn's "Antiquarian Library" (London, 1848).

ELLIS, SIR HENRY, an English author and antiquary, born in London in 1777. He was educated at St. John's college, Oxford, and in 1805 became one of the assistant librarians of the British museum. A new and enlarged edition of Brand's "Popular Antiquities" was issued under his care in 1813, and was republished in a cheaper form in 1842. In 1816 he wrote a careful and elaborate introduction to the "Domesday Book," and in 1824 published a series of "Original Letters illustrative of English History," from autographs in the British museum (3 vols. 8vo.); a second series, in 4 vols., in 1827; and a third, in 4 vols., in 1846. Sir H. Ellis was from 1827 to 1856 head librarian of the British museum.

ELLIS, WILLIAM, an English missionary and

author, born in the latter part of the last century. In 1815 he became officially connected with the London missionary society, under whose auspices, in Jan. 1816, he sailed with his wife for Polynesia. He spent nearly 10 years in promoting the spiritual welfare of the natives of the South sea islands (at one of which, Tahiti, he erected the first printing press in Polynesia), and in 1824 returned to England on account of the illness of his wife, stopping for some time on the way in the United States, where he received much attention. For some years he was employed in the business of the London missionary society at home, and published "Narrative of a Tour through Owhyhee" (8vo., London, 1826); "Polynesian Researches" (3 vols. 8vo., 1829); "History of Madagascar," compiled from information received from missionaries and government documents (2 vols. 8vo., 1839); "History of the London Missionary Society" (8vo., 1844); "Village Lectures on Popery" (8vo., 1851), &c. In 1835 his wife died, and 2 years later he was married a second time to Miss Sarah Stickney, with whom he resided for many years in Hoddeston, Hertfordshire, where Mrs. Ellis conducted a school for girls. In 1853 Mr. Ellis proceeded to Madagascar on a mission of observation for the London missionary society, and after three visits to that island published an interesting and valuable work, under the title of "Three Visits to Madagascar, during 1853-'56, with Notices of the People, Natural History, &c." (London, 1859), of which 2 republications have appeared in the United States.—SARAH STICKNEY, wife of the preceding, an English authoress, born in the beginning of the present century. Her parents belonged to the society of Friends, among whom she received her education. Her first literary production was a didactic work for the young, entitled the "Poetry of Life;" and since her marriage in 1837, she has written many volumes devoted to the moral and mental culture of her sex. The principal of these are: "Home, or the Iron Rule;" the well-known series, entitled the "Women of England" (1838), the "Daughters of England" (1842) the "Wives of England" (1843), and the "Mothers of England" (1848); "Look to the End" (2 vols. 8vo., 1845); "Hearts and Homes" (3 vols. 8vo., 1848-'9), &c. She is now (1859) engaged upon the preparation of a new work to be called "Mothers of Great Men." Her publications, numbering between 20 and 30, have exercised a beneficial influence in the domestic life of Great Britain and the United States.

ELLISTON, ROBERT WILLIAM, an English actor, born in London, April 7, 1774, died there, July 7, 1831. He was educated at St. Paul's school, but at the age of 17 ran away and joined a theatrical company at Bath, where he made his first appearance on the stage in April, 1791. Five years later he made his debut in London, at the Haymarket theatre, and in 1806 became principal actor and acting manager of that house. In the succeeding year he was

engaged at Drury Lane, but after the burning of the theatre, having quarrelled with Thomas Sheridan, he left the company, and opened the Surrey theatre. On the rebuilding of Drury Lane he was again engaged as a leading actor, and recited the address written by Lord Byron for the opening night. In 1819 he became the lessee of Drury Lane, but in 1826 retired a bankrupt. Subsequently he was again manager of the Surrey theatre, and continued occasionally to perform his principal characters until the close of his life. Elliston was called the first comedian of his time. His chief merit perhaps was the facility with which he adapted himself to every variety of characters, from the broadly humorous to the tragic. He possessed an inordinate self-esteem, and many anecdotes are told of his whimsical eccentricities.

ELLORA, ELORA, or ELOURO, a decayed town of Hindostan, in Hyderabad, 13 miles N. W. from Aurungabad, and celebrated for its cave temples, excavated from the inner slope of a horse-shoe-shaped hill, about a mile from the town. These caverns are sculptured over an extent $1\frac{1}{2}$ mile in length, and may be regarded as a Hindoo pantheon, since every divinity of India has there a shrine. Most of the caves are not less than 100 feet in depth; 20 of them are consecrated to Siva, and 2 to the Trimurti, or Brahminic trinity. They are all adorned with colossal statues and innumerable sculptures and bass-reliefs. The greatest and most remarkable of these monuments is the *Kailasa*, or paradise, dedicated to Siva, and designed to represent the court of that divinity where he receives those of his worshippers who, having escaped metempsychosis, come after death to enjoy eternal happiness. This does not, like the others, extend subterraneously, but rises to a lofty height in a vast excavation. It is composed of a portico, a chapel, and a grand pagoda. The portico is sustained by pillars and flanked by curious sculptures. Two obelisks, 60 feet in height, and 2 gigantic elephants, surround and support the chapel, which is likewise adorned on every side by statuary. The pagoda rises from the centre of the whole structure to the height of 95 feet, and is surrounded externally by mythological designs and sculptures representing lions, tigers, elephants, and fantastic animals of all sorts. Within are 42 colossal figures of Hindoo divinities, each one the centre of a group; and beyond this main temple may be seen others of smaller size and similar decorations. These gigantic works are of unknown antiquity, and seem to have been executed by Buddhists as well as by Brahmins. The village of Ellora is small, and is resorted to by numerous pilgrims.

ELLSWORTH, a port of entry, and capital of Hancock co., Maine, on both sides of the Union river, a navigable stream, which empties into Frenchman's bay about 4 miles below this point, the opposite banks being connected by 4 bridges; pop. in 1850, 4,009; in 1854, about 5,000. Ellsworth is one of the most flourishing

towns in the state, and a place of commercial importance. It is extensively engaged in the lumber trade, exporting every year about 50,000,000 feet of lumber. It contains the county buildings, and in 1859 had 2 churches, a high school, a newspaper office, 2 hotels, 2 banks, 9 saw mills, 2 grist mills, 9 lath machines, 1 shingle factory, 1 tannery, 1 machine shop, 1 carding mill, 1 pottery, 8 brick yards, and 13 ship-building yards. Capital invested in manufactures, about \$2,000,000. The tonnage of the district (Frenchman's bay), June 30, 1858, was 27,632 enrolled and licensed, and 6,783 registered.

ELLSWORTH, OLIVER, LL.D., 2d chief justice of the United States, born in Windsor, Conn., April 29, 1745, died Nov. 26, 1807. He was graduated at the college of New Jersey in 1766, and soon after commenced the practice of law. In 1777 he was chosen a delegate to the continental congress, and in 1780 was elected a member of the council of Connecticut, in which body he continued till 1784, when he was appointed a judge of the superior court. In 1787 he was elected to the convention which framed the federal constitution, and was afterward a member of the state convention, where he earnestly advocated the ratification of that important instrument, which his exertions had essentially aided in producing. In 1789 he was chosen a senator of the United States, which station he filled till 1796, when he was nominated by Washington chief justice of the supreme court of the United States, over which he presided with great distinction, his opinions being marked by sound legal and ethical principles, in clear and felicitous language. In 1799 he was appointed, by the elder Adams, envoy extraordinary to Paris, and with his associates, Davie and Murray, he successfully negotiated a treaty with the French. This accomplished, and his health beginning to fail, he visited England for the benefit of its mineral waters; but his infirmities increasing, he resigned his office of chief justice in 1800. Returning to Connecticut, he was again elected a member of the council; and in 1807 he was appointed chief justice of the state, which office he declined, under the impression that he could not long survive under the distressing malady which soon closed his days. He was eminently distinguished both for public and private virtues, and his reputation was so irreproachable that in the hottest partisan conflicts his character was never assailed.

ELLWOOD, THOMAS, a minister of the Friends, a friend of Milton, born in Crowell, Oxfordshire, in 1689, died in 1713. At an early age he attached himself to the society of Friends, thereby giving great offence to his father, but neither blows nor persuasions could induce the son to renounce his new sentiments, to take off his hat before his parents, or to address them with other pronouns than "thou" and "thee." He was, like most of the other ministers of his time, the author of numerous controversial works. The most considerable of these is his "Sacred

History of the Old and New Testaments." He also wrote a poem entitled *David's*, of which King David was the hero. But he is chiefly known from the circumstance that he was one of those selected by the poet Milton to read to him after the loss of his sight. During the raging of the plague in London in 1665 he obtained a retreat for Milton at Chalfont, and there he is said first to have suggested the idea of the "Paradise Regained."

ELM (*ulmus*, Linn.), a tree of the natural order *ulmaceæ*, which embraces some of the noblest and most important species in the United States. All the plants belonging to this family have simple, rough, serrate, unequal-sided leaves; flowers small, in bunches on the side of the twigs; the fruit either a winged samara or a drupe. Three genera of *ulmaceæ* are found within the limits of the United States. The most conspicuous of these is *ulmus*, of which we especially notice the white or American elm (*U. Americana*, Linn.). No tree can surpass this in the beauty of its proportions. In old trees especially, from the wide-spreading, buttress-like roots to the wider spreading branches, the curvature is beautiful and graceful in the extreme. Situation seems, however, to give variety to the outline. In wet pastures or similar places, a tall, slender trunk, crowned with a few pendent limbs, and clothed nearly from the ground with a feathery investment of small branches, which are scarcely more than leafy branches of twigs, is a pleasing object seldom overlooked or casually regarded. The rapidity of the growth of the white elm adapts it to artificial planting where shade is soon needed. Hardy to an unusual degree, it soon becomes a favorite with the tree planter, ranging in its distribution from Saskatchewan on Hudson's bay to Georgia. The wood of the white elm is used for making hubs of wheels, and is preferred for that purpose to any other native wood. Yokes are made of it, and near the coast ship blocks are constructed of its timber. The white elm grows readily from seed, which should be sown as soon as ripe, and may be gathered in almost any desirable quantity from the ground under the trees, falling as early as June. The seeds should be very slightly covered, and the young plants will rise in a few weeks, when they should be watched and weeded, and in succeeding seasons should be thinned out and transplanted to insure well-formed trees. In transplanting full-grown and vigorous young specimens found where they have appeared spontaneously, it is necessary to secure as many of the fibrous roots as possible, and have them spread out in large and ample holes, well prepared with good soil; care must be taken not to have them too deeply covered. The slippery elm (*U. fulva*, Mx.) is a much smaller tree, with larger and more beautiful foliage, and soft, downy, rusty-haired buds, whence the name sometimes applied of red elm. Its flowers are in lateral clusters; the samara is larger and with a broader border. The inner bark contains a great quan-

tity of mucilage, of much value in medicine. Michaux considers its wood as superior to that of the white elm. The tree can be readily grafted upon the white elm, and if only for ornament it is well worthy of cultivation. The corky white elm (*U. racemosa*, Thomas) has its branches often beset with corky ridges; its leaves are similar to those of the white elm; its flowers are in racemes; its wood is tougher and finer grained. The wahoo or winged elm (*U. alata*, Mx.) is a small tree, seldom exceeding 30 feet in height, has a fine-grained, valuable wood, and is to be found in Virginia and southward. The English elm (*U. campestris*, Linn.) was early introduced into this country, and is a stately tree, contrasting finely with the American. Its branches, unlike that, tend upward, or else spread more horizontally, and its foliage is of a darker green and more pleasing to the eye. The wych elm (*U. montana*, Bauhin) has been partially introduced; it is much cultivated in Scotland, and goes by the name of the Scotch elm. It resembles the slippery elm. The nuttle tree has a trunk from 20 to 60 feet high. Its leaves are obliquely lanceolate, acuminate, sharply serrate; its fruit is a sort of plum or drupe of a yellowish green color. It has several varieties, considered by some botanists as distinct species, but probably nothing more than forms of *celtis occidentalis* (Linn.). They grow on the poorest and most arid soils, but flourish best in a rich and moist ground. Michaux says that the wood of the hackberry (*C. crassifolia*, Mx.) is fine-grained and compact, but not heavy. The planer tree (*planera aquatica*, Gmelin) has small leaves like those of elms; the flowers are borne in small axillary clusters; the fruit is nut-like. According to Michaux, it grows on wet banks in Kentucky and southward. He considers its wood as hard, strong, and proper for various purposes. It has not, however, been put to any use in this country, and is so little esteemed as to have received no popular name. It is worthy of attempts at cultivation northward, and can be readily propagated by grafting it upon the elm.

ELMACINUS, or EL MACIN, GEORGE, known in the East by the name of Ibn Amid, an Arabian historian, born in Egypt in 1223, died in Damascus in 1273. He was a Christian, and held at the court of the sultans of Cairo the office of *ketib* or secretary. He wrote a history of the East, especially of the Arabs, from the creation of the world to his time, a portion of which was published both in Arabic and Latin by Erpenius, at Leyden, in 1625; the Latin version was soon reprinted, and was followed by a French translation. A complete edition in Arabic remains in use among the Christians of the Levant.

ELMES, JAMES, an English architect, born in London, Oct. 15, 1782. He practised his profession in the early part of his life, and gained the silver medal in architecture at the royal academy in 1804. He was for some time surveyor and civil engineer of the port of London,

but loss of sight, which, however, he afterward partially recovered, caused him to relinquish the office in 1828. He has published "Memoirs of the Life and Works of Sir Christopher Wren" (4to., London, 1823); "Lectures on Architecture" (8vo., 1823); "General and Bibliographical Dictionary of the Fine Arts" (8vo., 1826); "On the Law of Dilapidations" (royal 8vo., 1826); "Treatise on Architectural Jurisprudence" (8vo., 1827). Among his most recent productions is a work on Thomas Clarkson (London, 1854).

ELMINA, or **ST. GEORGE DEL MINA**, a town in Ashantee, W. Africa, capital of the Dutch settlements on the Gold Coast, on a small bay near the mouth of the river Beira, 5 or 6 m. W. of Cape Coast Castle. It is a large and dirty town, containing a considerable native population of traders, fishermen, servants, and artificers, the last being very numerous and mostly held as slaves. There are several country residences and farms belonging to the governor and merchants, back of which is an undulating country covered with dense forests. The fortress, situated on a low, rocky peninsula, is very strong, and was the first European establishment on this coast. It was built by the Portuguese in 1481, captured by the Dutch in 1637, and finally ceded by Portugal to the latter nation with other possessions in 1641.

ELMIRA, a post village and township and the capital of Chemung co., N. Y.; pop. in 1855, 8,486. It is situated on Chemung river, near the mouth of Newtown creek, and has easy communication both by land and by water with all the principal cities of the northern and middle states. The New York and Erie railroad crosses the river at this point; the Williamsburg and Elmira railroad connects with other roads to Philadelphia, and the Elmira, Canandaigua, and Niagara Falls railroad opens a communication to Canada. It is also on the line of the Chemung and the Junction canals, the former uniting it with Seneca lake and the latter with the central parts of Pennsylvania. It presents every indication of prosperity, and has increased more rapidly than any other place on the New York and Erie railroad. It is well laid out, and contained in 1859 the county buildings; 9 churches, viz.: 2 Baptist, 1 Congregational, 1 Episcopal, 3 Methodist, 1 Presbyterian, and 1 Roman Catholic; 1 daily and 2 weekly newspaper offices, numerous good schools and academies, 5 grist mills, 10 saw and 2 planing mills, 1 manufactory of edge tools, 2 of soap and candles, 4 of coaches and wagons, 1 of woollen goods, 1 car factory and repair shop, 8 breweries, 4 furnaces, 3 machine shops, 4 tanneries, gas works, &c. Elmira is the seat of a female college capable of accommodating 800 pupils.

ELMORE, **FRANKLIN HARPER**, an American financier and politician, born in Laurens district, S. C., in 1799, died in Washington, D. C., May 29, 1850. He was graduated at South Carolina college in 1819, subsequently studied law, and in 1821 was admitted to the bar. In 1822 he

was elected the solicitor, or public prosecuting officer, of the southern circuit, an office which he retained by successive reëlections until 1836, when he was chosen a representative to fill a vacancy in the 24th congress. He subsequently served throughout the 25th congress, and in 1839 was made president of the bank of the state of South Carolina, which position he held with credit until elected in 1850 to fill the vacancy in the U. S. senate occasioned by the death of Mr. Calhoun. He died immediately after entering upon the duties of his new office. In 1838 he was selected by the South Carolina delegation in congress as one of a committee to obtain authentic information respecting the anti-slavery movement. He addressed, Feb. 16, 1838, a letter to James G. Birney, corresponding secretary of the American anti-slavery society, enclosing a series of interrogatories as to the number of anti-slavery societies and members in the United States, their objects, expectations, means, and modes of operation. Mr. Birney replied at great length in a letter, which, with the other letters on both sides, was printed, and went through many editions under the title of "The Elmore Correspondence."

ELMSLEY, **PETER**, an English scholar, born in 1773, died March 8, 1825. He was educated at Westminster school, and at Merton college, Oxford, and was graduated master of arts in 1797. He officiated for a time to a small chapel in Little Horkesley; but becoming master of a fortune by the death of an uncle, he devoted himself from that time to literary studies, and particularly to Greek literature. He lived for a while in Edinburgh, where he was intimately associated with the founders of the "Edinburgh Review," and contributed to that periodical several articles, among which were reviews of Heyne's "Homer," Schweighäuser's "Athenæus," Blomfield's "Prometheus," and Porson's "Hecuba." In 1816 he made a voyage to Italy in search for manuscripts, and passed the winter of 1818 in researches in the Laurentian library at Florence. The next year he was appointed to assist Sir Humphry Davy in the unavailing task of trying to decipher some of the papyri found at Herculaneum. After his return to England he published editions of several of the Greek tragedies.

ELOCUTION. See **ORATORY**, and **VOICE**.

ELOHIM, one of the Hebrew names of the Deity, the plural of *Eloah*. The name is also applied to angels, princes, judges, great men, and even to false gods.

ELPHINSTON, **JAMES**, a Scotch grammarian, born in Edinburgh in 1721, died in Hammersmith, Oct. 8, 1809. He studied at the university of Edinburgh, became tutor to Lord Blantyre, superintended an edition of the "Rambler" in his native town, and in 1751 opened a school at Kensington. He was a zealous advocate of a change in English orthography, and published several works on the subject which exposed him to great ridicule. A translation of Martial (4to., 1782) was no better received.

His principal works are: "French and English Languages" (2 vols. 12mo., 1756); "Education, a Poem" (1763); "English Language" (2 vols. 12mo., 1765); "Propriety ascertained in her Picture" (1786); *Poetae Sententiosi, Latini, &c.* (1794); "Fifty Years' Correspondence, English, French, and Latin, in Prose and Verse, between Geniusses of both Sexes, and James Elphinstone" (8 vols. 12mo., 1794).

ELPHINSTONE, GEORGE. See KEITH.

ELPHINSTONE, MOUNTSTUART, 4th son of John, 11th Baron Elphinstone, an English statesman and historian, born about 1780. He entered the service of the East India company at an early age, was made assistant to the judge of Benares, rose rapidly to the post of resident at Poonah, and in 1809 was sent as ambassador extraordinary to the Afghan court at Cabool, where he succeeded in concluding a treaty against the French. The overthrow of the Afghan monarch in the same year rendered the compact inoperative, but, as the fruit of this mission, Mr. Elphinstone published his valuable "Account of the Kingdom of Cabul and its Dependencies in Persia, Tartary, and India," (4to., London, 1815), which has been twice reprinted. His conduct at Poonah during the troubles with the peishwa in 1817 was highly praised. He introduced many reforms in his district, and in Oct. 1818, was named governor of Bombay, on assuming which station he addressed to the Calcutta government a "Report on the Territories conquered from the Peishwa." His liberal policy, care of education, and study of the welfare of the natives, are commended by Bishop Heber in his "Indian Journal." Mr. Elphinstone retired from the Indian service in 1826, and on his departure for England the citizens of Bombay presented him with a service of plate, and founded in his honor the institution in Bombay which bears his name. In 1841 he produced his "History of India; the Hindoo and Mahometan Periods" (2 vols. 8vo.), a third edition of which appeared in 1848.

ELPHINSTONE, WILLIAM, a Scotch prelate and statesman, born in Glasgow in 1437, died in Edinburgh, Oct. 25, 1514. He was educated at the university of Glasgow, received the degree of M.A., applied himself to theological studies, and was for 4 years rector of Kirkmichael, in Glasgow. Subsequently, while studying in Paris, he attracted the attention of the university by the extent and variety of his learning, and was appointed to the professorship of civil and canon law, first at Paris, and afterward at Orleans. After residing 9 years in France, he returned to Scotland, was made rector of the university at Glasgow and official or commissary of 2 dioceses, and at the same time was called to a seat in parliament and in the privy council. He settled a misunderstanding between James III. of Scotland and Louis XI. of France, and prevented a war. He was made bishop of Ross about 1480, and was successful in a second diplomatic mission in arranging a truce between Scotland and England, after

which he was made lord high chancellor of Scotland. He was called to take part at the coronation of James IV. in 1488, and was immediately after sent as an ambassador to the emperor Maximilian to negotiate a marriage between the king of Scotland and the emperor's daughter; and on his way he concluded a treaty of alliance between Scotland and the states of Holland. At his suggestion the pope granted, in 1494, authority for the foundation of King's college in Old Aberdeen, which was erected in 1506. He wrote the lives of the Scottish saints, a work which has not reached our times, and a history of Scotland, which is still preserved in the Bodleian library at Oxford. After the defeat and death of James IV. at Flodden he was never seen to smile, and his death has been attributed to grief at that disaster.

ELSINORE, or ELSINER (Dan. *Helsingør*), a maritime town of Denmark, in the bailiwick of Frederiksborg, island of Seeland, 23½ m. N. E. from Copenhagen; lat. 56° 2' 11" N., long. 12° 36' 49" E.; pop. about 8,000. The town is built on the narrowest part of the sound, here but 3½ m. in width, opposite the Swedish town of Helsingborg. It commands the principal passage between the Cattegat and the Baltic, and is the spot where the sound dues (abolished in 1857) were formerly paid by all foreign vessels, except those of Sweden, navigating that channel. The town is substantially but irregularly built on ground rising gradually from the shore, with one main street crossed by others at right angles, and contains 2 churches, a town hall, a high school, an infirmary, a hospital, a theatre, and a cemetery beautifully laid out. The harbor is little more than the shelter afforded by a wooden pier, but the roadstead is excellent and is generally crowded with vessels. Adjacent to it, on the N. E., on a tongue of land running out into the sea, is the castle of Kronborg (Crown castle), built by Frederic II. about 1580. Modern fortifications have since added to its strength. It is now chiefly used as a prison. Caroline Matilda, queen of Christian VII., was imprisoned here until the interference of her brother, George III. of England. Under the castle are casemates capable of holding 1,000 men. According to a popular tradition, Holger Danske, the legendary hero of Denmark, resides in one of the subterranean vaults. In the courtyard of the castle is the lighthouse, showing a fixed light 113 feet above the sea level. A short distance N. W. of the town is the palace of Marienlyst (Mary's delight), once a royal residence, but now in private occupation. Near by is shown a pile of rocks, erroneously called the tomb of Hamlet, of whose story, as told by Shakespeare, Elsinore is the scene. Elsinore enjoys a good foreign trade. Most of the maritime nations have consuls, and several British mercantile houses have agencies here. Local industry is mostly engaged in the refining of sugar and brandy, printing cottons, fishing, &c. As the principal communication be-

tween Sweden and the continent passes through this port, facilities for travel are abundant. Steam communication exists with Copenhagen and Helsingborg. An extensive manufactory of arms is in operation at Hammerwolle, in the suburbs. Elsinore was erected into a city in 1425; was taken and burned by the forces of Lübeck in 1522, and again in 1535 by Christian II. It was enlarged by the Dutch colonists in 1576. The castle was taken, Sept. 6, 1658, by the Swedes, under the orders of Gen. Wrangel, but was restored to the Danes in 1660. It failed to prevent the passage of the British fleet under Sir Hyde Parker, with Nelson as his second in command, in 1802.

ELSSLER, FANNY and THERESE, two sisters celebrated as dancers, born in Vienna, Therese in 1808, Fanny in 1811. Fanny, the more famous, was instructed in the juvenile ballet corps of the Viennese theatre, and at the age of 6 made her appearance on the stage. Subsequently she received instructions from Aumer, and a marked influence upon her general æsthetic culture was exercised by Baron Friedrich von Gentz. The two sisters, who were inseparable, gave performances at Naples for some time, and in 1830 made their first appearance at Berlin. Here the public had been in some measure prepared for Fanny's talent by the account given of her by Gentz to his friend Rahel Varnhagen von Ense, but her poetical conceptions of her art, and graceful presence, far surpassed all expectations. Henceforward her career assumed the character of a series of triumphal ovations. Vienna, which had been so slow to appreciate her, soon joined the general chorus of enthusiasm. While engaged at Berlin she made occasional excursions to London and other cities, and in 1834 she reached France. The sisters made their first appearance before a Parisian audience, Sept. 19, in *La tempête*, a ballet adapted from Shakespeare's "Tempest," by Adolphe Nourrit. Fanny was received with much applause, and considered entitled to the same rank with Taglioni, then at the head of her profession in Paris. She, however, found an occasion to eclipse her celebrated rival in the Spanish cachucha, a dance which she introduced for the first time in the ballet of *Le diable boiteux*. This was received with prodigious applause. The noted Dr. Véron offered her his hand; Jules Janin was in ecstasy; a romantic young Pole glorified her in *Lettres à une artiste* published by him at Brussels; Paris proclaimed her inimitable. In 1841 the sisters visited the United States, where they met with brilliant success, and afterward reaped another harvest of gold and glory in Russia. In 1851, after giving a few farewell performances at Vienna, Fanny retired from the stage with an immense fortune, and now resides at a villa near Hamburg. Her sister, who retired at the same time, contracted, April 25, 1851, a morganatic marriage with Prince Adalbert, of Prussia, and was ennobled under the title of Frau von Barnem.

ELTON, a salt lake in the government of Saratov, Russia, 70 m. E. of the Volga, and 180

sq. m. in extent. It yields annually upward of 100,000 tons of salt, the collection of which gives employment to 10,000 persons. In the hottest season the crystallized salt along its banks and on its surface gives it the appearance of a vast sheet of ice or frozen snow. It is nowhere more than 15 inches deep.

ELVAS, a fortified frontier town of Portugal, in the province of Alemtejo, 10 m. W. of Badajos, on a hill near the bank of the Guadiana; pop. 16,460. It is an important stronghold, having an arsenal, and spacious bomb-proof barracks. The fort of La Lippe on a neighboring hill is deemed impregnable. The town itself is poorly built, and many of the venerable Moorish buildings which line its streets are crumbling to pieces. It is supplied with water from a distance of 8 miles, by means of a fine Moorish aqueduct. During the peninsular war in 1808 Elvas was taken by the French under Marshal Junot, and held during several months.

ELVES, genii of the northern mythology, forming, according to some classifications, with the undines, salamanders, and gnomes, groups of elementary sprites identified respectively with the water, fire, earth, and air. The elves are of the air, and have been more widely received in the faith and poetry of Europe under this name than under their Hellenic name of sylphs. They are capricious spirits, of diminutive size but preternatural power. Their stature is less than the size of a young girl's thumb, yet their limbs are most delicately formed, and when they will they can hurl granite blocks, bind the strongest man, or shake a house. They are divided in the sagas into good and bad, or light and dark elves, the former having eyes like the stars, countenances brighter than the sun, and golden yellow hair, the latter being blacker than pitch, and fearfully dangerous. The elves ordinarily wear glass shoes, and a cap with a little bell hanging from it. Whoever finds one of these slippers or bells may obtain from the elf who has lost it any thing which he asks for. In the winter they retire to the depths of mountains, where they live in much the same way as men, and in the first days of spring issue from their grottoes, run along the sides of hills, and swing upon the branches of the trees. In the morning they sleep in blossoms or watch the people who pass by, but at the evening twilight they meet together in the fields, join hands, and sing and dance by the light of the moon. They are generally invisible, but children born on Sunday can see them, and the elves may extend the privilege to whomsoever they please. In England and Scotland they were subject to a king and queen. The islands of Stern and Rugen, in the Baltic, are especially subject to the king of the elves, who rides in a chariot drawn by 4 black horses, and whose passage from island to island is recognized by the neighing of the steeds, the blackness of the water, and the bustle of the great aerial company who follow in his train. The elves sometimes become domestic servants, and would be valuable as such

if they were less easily offended and less dangerous after taking offence. As long as their caprices are gratified, their food and drink regularly left at an appointed place, and no attempt made to interfere with their freedom, the furniture is sure to be dusted, the floor to be swept, and every chamber to be perfectly in order. But the brothers Grimm, in their *Deutsche Sagen*, have chronicled the misfortunes of many a young girl, who, having called an elf to her aid, repented too late of having offended it. The brownie of Scottish fame is one of these domestic elves.

ELWES, JOHN, an English miser, born in Southwark about 1712, died Nov. 26, 1789. His own family name was Meggot, but he exchanged it for that of his uncle, from whom he received a large inheritance. At an early period of his life he attended Westminster school, and became a good classical scholar, though at no subsequent period was he ever seen with a book. He was sent to Geneva to complete his education, and there distinguished himself as one of the boldest riders in Europe. After returning to England he began to indulge in gambling, frequenting the most noted gaming houses, and sitting up whole nights with the most fashionable and profligate men of the time. After thus making or losing thousands, he would go to the cattle market at Smithfield and dispute with the butchers for a shilling. He next took to hunting, and his stable of foxhounds was considered the best in the kingdom, yet he kept but a single servant to attend to all his cows, dogs, and horses. From his parsimonious mode of life his fortune rapidly increased, and when worth half a million he refused to accept a seat in parliament unless on the express stipulation that he should be brought in for nothing, and, owing to peculiar circumstances, was actually elected. His miserly habits increased with his fortune, and during the latter years of his life he abandoned gaming, hunting, and every comfort, and died the possessor of £800,000, after having suffered greatly from fear of poverty.

ELY, a city of Cambridgeshire, England, on an eminence near the Ouse, 16 m. N. N. E. from Cambridge; pop. in 1851, 6,176. It consists principally of one street, and contains many old buildings. It is the seat of a bishopric which was founded in 1107. Its cathedral is a splendid structure, built in successive centuries, and presenting a singular mixture of the Saxon, Norman, and early English styles of architecture. The churches of St. Mary and of the Holy Trinity are also remarkable both for their age and splendor. A famous convent was founded here about 670 by Ethelreda, wife of Oswy, king of Northumberland, and she became its first abbess. It was destroyed by the Danes in 870, and 100 years later was rebuilt by Ethelwold, bishop of Winchester, who placed in it monks instead of nuns. Ely has important manufactures of earthenware and tobacco pipes, extensive gardens in its vicinity, the produce of which is sent to the London and Cambridge

markets, and several benevolent institutions and schools, among which is a grammar school founded by Henry VIII. It is the capital of a division of Cambridgeshire, called the "isle of Ely," separated from the rest of the county by the Ouse. This district is included in the reclaimed marsh known as Bedford Level.

ELYMAIS, in the Bible Elam, now Luristan, a province of Susiana, now Khoozistan, in Persia, a mountainous region, watered by the Eulæus (Heb. *Ulai*), and inhabited by a people of Semitic descent (Genesis x. 22). The people of Elam appear as bold and rude mountaineers, skilled in archery, and are often mentioned in connection with some warlike expedition, from the battle of Chedorlaomer, in the time of Abraham, down to the conquest of Babylon by the Medes and Persians. In Isaiah (xxi. and xxii.), we see them marching with their mighty quivers, with chariots and horses, to fatal sieges; in Jeremiah (xlix.), we see their bow, their chief strength, broken; in Ezekiel (xxxii.), we find them among those inhabitants of the nether world who had spread their terror among the living. (See SUSIANA.)

ELYSIUM, or ELYSIAN FIELDS, among the Greeks and Romans, the dwelling place of the blessed after death. While the oriental and most other peoples sought this abode in the upper regions of the sky, the Greeks placed it in the west on the ends of, or beneath, the earth, where the sun goes down. According to Homer, Elysium was a plain on the ends of the earth, where men live without toil or care, where there is neither snow, nor winter storms, nor rains; where the lovely and cooling zephyrs blow unceasingly with light murmur, and where dwell Rhadamanthus, who, in the upper world, was the justest of men. The position of Elysium changed with the progress in geographical knowledge, proceeding further and further to the west. Hesiod speaks of the happy isles of the ocean, and other writers supposed it to be somewhere in the Atlantic, till Pindar and the later poets put it beneath the earth. According to the later descriptions, the meads of Elysium 3 times in a year brought forth the most beautiful flowers. The inhabitants enjoyed the reward for their virtues on earth, and whoever had 3 times resisted a temptation to do evil attained to this abode. A never-setting sun shone upon them, and melancholy was removed far away. The airs, fragrant and tinted with purple, breathed softly from the sea, the flowers were twined into wreaths for the dwellers, peaceful waveless rivers flowed by, and horse races, games, music, and conversation, occupied the hours. According to Homer, Rhadamanthus alone ruled Elysium, being admitted there on peculiar grounds as the representative of the idea of justice. Hesiod knows Elysium only by the name of the isles of the Blessed, where Kronos rules, and the Titans and other Homeric heroes dwell.

ELZEVIR, or more properly ELAEVIR or ELZEVIER, the name of a family of Dutch print-

ers, established at Leyden, Amsterdam, the Hague, and Utrecht, in the 16th and 17th centuries, and who for nearly a hundred consecutive years were distinguished for the number and elegance of the publications, especially the editions of ancient authors, which issued from their press.—Louis, the founder of the family, born in Louvain in 1540, emigrated to Holland in 1580, in consequence of the religious troubles which agitated his native city, and settled in Leyden, where he died, Feb. 4, 1617. He became a petty officer of the university of Leyden, and also engaged in the business of a bookseller and printer. In the latter capacity he is said to have produced, between 1583 (when the *Drusii Ebraicarum Quæstionum ac Responsionum libri duo*, the first book bearing the imprint of Elzevir, appeared) and his death, 150 works. He is said to have been the first printer who observed the distinction between the vowels *i* and *u* and the corresponding consonants *j* and *v*. Of the 7 sons of Louis, 5 followed the business of their father, viz.: MATTHEUS, who was established at Leyden, where upon his death in 1640 he was succeeded by his son Abraham; LOUIS (II.), who in 1590 established a printing house at the Hague, and died there in 1621; GILLES, who was in business at the Hague and subsequently in Leyden; JOOST, who settled in Utrecht; and BONAVENTURE, born in 1583, died in 1652. In 1626 the last named entered into a partnership with his nephew ABRAHAM, the son of Mattheus, at Leyden, which terminated only with their deaths in 1652, within a month of each other. They were the most distinguished of the family, and from their press issued those numerous exquisite little editions of the classics, as also those on history and politics (62 vols. 16mo.), called by the French *Les petites républiques*, with which the name of Elzevir is now most familiarly associated. The Livy and Tacitus of 1634, the Pliny of 1635, the Virgil of 1636, and the Cicero of 1642, are among the best of their productions. The business was carried on for two years by JAN, the son of Abraham, and DANIEL, the son of Bonaventure; afterward by Jan alone, and by his widow. Louis (III.), son of Louis (II.), founded the Elzevir printing establishment at Amsterdam in 1638, entered into a partnership with his cousin Daniel in 1654, which lasted 10 years, and died in 1670, at which time the reputation of the Elzevirs had reached its highest point. Among their chief publications are the celebrated New Testament of 1658, a series of Latin classics, the *Etymologicon Linguae Latinæ*, and an edition of the *Corpus Juris*. Between 1664 and 1680, the year of his death, Daniel carried on the business alone, and in that period published 152 works. He was the last of his family who excelled in printing, although his widow and PIETER, grandson of Joost, carried on the business for some years.—The merit of the Elzevirs consisted less in their learning or critical abilities, in which they were inferior to the Aldi, the Stephenses, and others of the celebrated printers of the 15th,

16th, and 17th centuries, than in the clearness and beauty of their type, the excellent quality of their paper, made in Angoulême, and in the general elegance of their publications. The texts of their editions of the classics were not founded on or collated by old manuscripts, as were those of many of their predecessors, who were scholars as well as printers, but were generally reprints, and were sometimes pirated from other sources. All their choice works, particularly the small editions of the classics, bring large prices at the present day; and the name Elzevir applied to a book has become a synonyme for typographical correctness and elegance. The Elzevirs printed several catalogues of their works, but the best account of them is to be found in the *Notice de la collection d'auteurs Latins, Français, et Italiens, imprimées de format petit en 12mo. par les Elzevier*, in Brunet's *Manuel du libraire* (Paris, 1820), and in Bérard's *Essai bibliographique sur les éditions des Elzevirs* (Paris, 1822). See also Pieter's *Annales de l'imprimerie Elzévirienne* (Ghent, 1851-'52), in which the number of works printed by the Elzevirs is stated at 1,213, of which 968 were in Latin, 44 in Greek, 126 in French, 82 in Flemish, 22 in oriental languages, 11 in German, and 10 in Italian. Their imprint was: *Apud Elzevirios*, or *Ex Officina Elzeviriorum* or *Elzeviriana*; and frequently the title page of their books contains a device of a blazing wood pile, emblematic of their name, compounded of *els*, alder, and *uur*, fire.

EMANCIPATION. See SLAVERY.

EMANUEL, an E. co. of Ga., bounded N. by the Ogeechee river, and S. W. by Pendleton's creek; area, about 1,000 sq. m.; pop. in 1852, 4,883, of whom 1,009 were slaves. The principal streams which intersect it are the Great Ochoopee and the Cannouchee. It has a level surface, and a sandy, unproductive soil. Timber is abundant. Cotton, grain, and potatoes are the chief agricultural staples, and in 1850 the county yielded 559 bales of cotton, 121,874 bushels of Indian corn, 2,259 of oats, and 49,389 of sweet potatoes. There were 17 churches, and 202 pupils attending public schools. Value of real estate in 1856, \$684,372. The county was organized in 1812. Capital, Swainsborough.

EMANUEL (Port. MANUEL) I., king of Portugal, called the Great, and the Happy, born in Alconchete, May 8, 1469, ascended the throne upon the death of John II. in 1495, died in Lisbon, Dec. 13, 1521. He was the son of Duke Ferdinand of Visen, grandson of King Edward of Portugal, nephew of King Alfonso V., and cousin of John II. His father, accused of conspiracy against John II., was slain by the latter with his own hand. Emanuel, bearing the title of the duke of Beja, was educated in Spain, where he married Isabella, daughter of Ferdinand and Isabella, and heir to the crown of Castile; after whose death in 1498 he married Donna Maria, her sister. He received the kingdom from his predecessors in a state of prosperity, and by his activity and sagacity raised

Portugal to her most brilliant point of power and glory. He signalized the beginning of his reign by pursuing with an ardor surpassing that of all his predecessors the long-sought passage by sea to India. Mainly under his patronage were made the voyages of Vasco da Gama, Albuquerque, and Pedro Alvarez de Cabral; in his reign Goa became a Portuguese settlement, and Brazil, the Moluccas, &c., were discovered; the commerce of the Indies was opened to Portugal, wealth accumulated, and a spirit of enterprise took possession of the nation, which could now boast of a brilliant succession of navigators and generals. Less successful were Emanuel's efforts for conquest in Morocco, where dearly purchased victories secured no lasting gain. He zealously devoted himself to the interests of the Roman Catholic church, sent missionaries on board all his fleets to convert whatsoever people they might discover, and sought to reform the character of the Portuguese ecclesiastics at home. He persecuted the Jews, banished the Moors, and introduced the inquisition. Though he ruled 20 years without convening the cortes, his home administration was marked by justice, and he gave completeness to the institutions of his kingdom by publishing a code of laws. He succeeded in remaining at peace with all Europe, and even preserved a difficult neutrality toward Francis I. and Charles V. He was a patron of men of letters, and himself the author of memoirs of the Indies. He was thrice married, his last wife being Eleonora of Austria, sister of Charles V.

EMBALMING (Gr. *βαλσαμον*, balsam or balm, from the resinous substances employed in the operation), the process of preserving animal bodies from corruption by introducing antiseptic substances into the spaces left vacant by the removal of the internal parts. The art was extensively practised by the ancient Egyptians, and the mummies found at this day in their sepulchres, where they have lain for 3,000 years or more, testify to the perfection it had reached in those remote periods. With them it was not limited to the preservation of human bodies alone, but no reptile appears to be so mean as not to have been held sacred and worthy of this care of its remains; and when, in addition to the countless bodies of human beings still to be found in the places where they were deposited, are reckoned the millions of dogs, apes, crocodiles, cats, ibises, bulls, rams, foxes, asps, &c., of more than 50 species in all, it is a matter of wonder whence were obtained all the resins, drugs, spices, &c., which are described as essential to the process. After Egypt became a Roman province the art continued to be practised, and was adopted to some extent by the Romans themselves. Among other races also the same practice has in former times prevailed; or at least a modification of it designed to produce a similar result; such, for example, as drying the bodies of the dead. This was probably the custom of the Guanches, the former inhabitants of the Canary islands. The ancient Peruvians preserved the bodies of

their incas, according to Garcilasso, "perfect as life, without so much as a hair or an eyebrow wanting." In the great temple of the sun at Cuzco their bodies, ranged on one side, and those of their queens on the other, sat clothed in their former princely attire upon chairs of gold, their heads inclined downward, covered with raven black or silver gray hair, and their hands placidly crossed over their bosoms. (Prescott's "Conquest of Peru," vol. i., p. 38.) Exposure of the bodies to the exceedingly dry and cold air of the mountainous region, it was thought by Garcilasso, was sufficient to preserve these bodies without recourse to the artificial processes adopted by the Egyptians. These have been particularly described by Herodotus and Diodorus Siculus, and the accounts of the former especially have been regarded by most authorities as presenting an exact exposition of them. Some, however, question the adequacy of the processes thus given to account for the results, and state that modern experimenters fail entirely of success in endeavoring to perform the operation by their instructions. The account given by Herodotus (ii. 86), is as follows: "There are a set of men in Egypt who practise the art of embalming, and make it their proper business. These persons, when a body is brought to them, show the bearers various models of corpses, made in wood, and painted so as to resemble nature. The most perfect is said to be after the manner of him [Osiris] whom I do not think it religious to name in connection with such a matter; the second sort is inferior to the first, and less costly; the third is the cheapest of all. All this the embalmers explain, and then ask in which way it is wished that the corpse should be prepared. The bearers tell them, and having concluded their bargain, take their departure, while the embalmers, left to themselves, proceed to their task. The mode of embalming, according to the most perfect process, is the following: They take first a crooked piece of iron and with it draw out the brain through the nostrils, thus getting rid of a portion, while the skull is cleared of the rest by rinsing with drugs; next they make a cut along the flank with a sharp Ethiopian stone, and take out the whole contents of the abdomen, which they then cleanse, washing it thoroughly with palm wine, and again frequently with an infusion of pounded aromatics. After this they fill the cavity with the purest bruised myrrh, with cassia, and every other sort of spicery except frankincense, and sew up the opening. Then the body is placed in natrum for 70 days, and covered entirely over. After the expiration of that space of time, which must not be exceeded, the body is washed, and wrapped round from head to foot with bandages of fine linen cloth, smeared over with gum, which is used generally by the Egyptians in the place of glue, and in this state it is given back to the relatives, who enclose it in a wooden case which they have had made for the purpose, shaped into the figure of a man. Then fastening the case, they place it in a sepulchral chamber, up-

right against the wall. Such is the most costly way of embalming the dead. If persons wish to avoid expense and choose the second process, the following is the method pursued: Syringes are filled with oil made from the cedar tree, which is then, without any incision or disembowelling, injected into the abdomen. The passage by which it might be likely to return is stopped, and the body laid in natrum the prescribed number of days. At the end of the time the cedar oil is allowed to make its escape; and such is its power that it brings with it the whole stomach and intestines in a liquid state. The natrum meanwhile has dissolved the flesh, and so nothing is left of the dead body but the skin and the bones. It is returned in this condition to the relatives, without any further trouble being bestowed upon it. The third method of embalming, which is practised in the case of the poorer classes, is to clean out the intestines with a clyster, and let the body lie in natrum the 70 days, after which it is at once given to those who come to fetch it away." Both with the Egyptians and Peruvians the same practice is said to have obtained of preserving all the internal parts extracted from the body in vases deposited near the mummies. Dr. Cormack of London, who has recently investigated the subject, is of opinion that the essential part of the process was the application of heat to the bodies, which were filled with some form of bitumen. By this means creosote was generated and diffused throughout all tissues of the body, and this method was never divulged, while the other operations may have been practised the better to conceal this, as well as to add dignity and mystery to the art.—The substances found in mummies are altogether of a resinous nature, and the tissue is impregnated with resinous matter; but this and the wine said to be employed could not preserve the animal substance. All parts, and the linen used for enveloping the body in folds sometimes of 1,000 yards, bear the marks of heat; the bandages are commonly reduced almost to tinder. The object of the gum with which they were smeared may have been to produce creosote by the calcination to which they were subjected. Bitumen also appears to have been employed in a liquid state for filling the cavities of the bodies, though no mention is made of heat being applied to effect its decomposition. The cost of the most expensive method of embalming was a talent of silver, about £187 10s., or, according to Calmet, about £300; £60 was a moderate price.—Thénard's "Chemistry" contains a description of a method employed in recent times by Dr. Ohausier. The body, thoroughly emptied, and washed in water, is kept constantly saturated with corrosive sublimate. The salt gradually combines with the flesh, gives it firmness, and renders it imputrescible and incapable of being injured by insects and worms. The author states that he had seen a head thus prepared, which for several years had been exposed to the alternations of sun and rain without hav-

ing suffered the slightest change. It was very little deformed, and easily recognized, although the flesh had become as hard as wood. A process has been introduced into France by J. N. Gannal of injecting a concentrated solution of sulphate of alumina into the veins of the body, which is employed for anatomical preparations as well as for embalming. Dr. Ure states that a solution of chloride of mercury and wood vinegar is most efficacious for similar uses. He is also of opinion from the statements of Pliny, that wood vinegar, the antiseptic virtue of which is in the creosote it contains, was the essential means employed by the ancient Egyptians in preparing their mummies, and that the odoriferous resins were of inferior consequence. M. Falconi, in a paper read to the French academy, states that after a series of experiments made with different salts, he finds that sulphate of zinc, prepared of different degrees of strength, is the best material. An injection of about a gallon would perfectly well preserve a dead body, as is proved by the preparations belonging to the anatomical cabinet at Genoa. Bodies so prepared preserve all their flexibility for 40 days. It is only after that period that they begin to dry up, still preserving, however, their natural color. Chloride of zinc and sulphate of soda are sometimes used also.

EMBANKMENT. See DIKE.

EMBARGO (Sp. *embargo*, an impediment), a public prohibition forbidding ships to sail, generally adopted with a view to impending hostilities. In 1794 the American congress laid an embargo for 60 days upon all vessels in the ports of the confederation. This was said by the opponents of the measure to be done to obstruct the supply of provisions to the British forces in the West Indies, then engaged in hostilities against the French republic. But the embargo most famous in American history is that intended to countervail Napoleon's Berlin and Milan decrees and the British orders in council. On Dec. 22, 1807, on the recommendation of President Jefferson, a law was enacted by congress prohibiting the departure from the ports of the United States of all but foreign armed vessels with public commissions, or foreign merchant ships in ballast, or with such cargo only as they might have on board when notified of the act. All American vessels engaged in the coasting trade were required to give heavy bonds to land their cargoes in the United States. This embargo was repealed by an act passed Feb. 27, 1809, and taking effect March 15, 1809, except so far as related to France and Great Britain and their dependencies; and in regard to them also it was to take effect after the conclusion of the next succeeding session of congress. A 3d embargo, laid April 4, 1812, was superseded by the declaration of war against England, June 18, 1812. A 4th embargo was laid by act of Dec. 19, 1813, prohibiting all exports whatever, and even stopping the coasting trade; fishermen were required to give bonds not to violate the act. This was repealed 4 months afterward.

EMBER DAYS, certain days set apart by the church as early as the 8d century for the purpose of prayer and fasting. They are the Wednesday, Friday, and Saturday after the 1st Sunday in Lent, after the feast of Whitsunday, after the 14th of September, and after the 13th of December. The weeks in which these days fall are called ember weeks. The name is probably of Anglo-Saxon derivation, meaning the circular days, and in the canons they are termed the *quatuor anni tempora*, the 4 cardinal seasons. Some, however, have supposed the name to be taken from the ancient custom of using ashes or embers in connection with fasting.

EMBEZZLEMENT, the wrongful appropriation of the goods of another, differing from larceny in this, that in the case of embezzlement the property is in the possession or control of the wrong doer. It was therefore not an indictable offence at common law, and the owner of the property embezzled had no other remedy but a civil action for damages, or in some cases for the recovery of the property itself. Thus if a man hired a horse and fraudulently sold him, if the sale was made in the usual course, *i. e.* in market overt, and there was nothing to put the purchaser upon his guard, the sale was valid, and the owner could only recover damages against the man who had committed the fraud; but if a horse had been stolen, although it should afterward have been sold in market overt, the title did not pass, and the owner could reclaim his property. It has never been settled by a positive rule of general application what would be sufficient notice to the purchaser in the case of a fraudulent sale of property intrusted to another. Any circumstance that should have put him upon inquiry would be deemed equivalent to actual notice, and in such a case the sale would not be deemed *bona fide*. Whenever there are circumstances indicating that there is possession without property or only for a special purpose, as in the case of a pawnbroker or common carrier, the rule would apply that the purchaser takes the risk of any fraud that may be committed by the seller. So in cases of sale by the owner, but of non-compliance with the conditions of sale by the vendee, a difficult question sometimes arises. Actual delivery of the property to the vendee with the intention of giving him the ownership, even if such delivery was obtained by fraudulent representations, or if a fraud was committed by not paying for the property, if the price was payable on delivery, still transfers the right of property so far that the fraudulent vendee can make a valid sale to another person who is ignorant of the fraud; but the owner will have the right to reclaim the property from the vendee himself so long as it is in his possession, unless a claim by creditors of the vendee should intervene. Thus, although stolen property could be reclaimed, in whose hands soever it should be found, yet in the case of embezzlement, which was in fact a greater offence than larceny, the ownership might be lost; nor was the offender

punishable criminally, except in the case of a common carrier who should break open a cask, bale, or package of goods, and appropriate a part of the contents, or should carry off the entire cask, bale, or package after it had been brought to its destination, which appropriation or carrying off was held to be larceny. To remedy this defect, various statutes have been enacted whereby the embezzling of the goods of a master by a servant, or by a clerk or person employed, provided such servant or clerk had the custody of the goods, was made felony; so of a guest in an inn, or a lodger in furnished rooms, carrying off any of the effects which he had possession of for use, it was declared to be larceny. Severe penalties were also enacted against embezzlement by clerks in the post office, or by brokers, bankers, attorneys, &c., of any moneys or valuable securities placed in their hands for safe keeping or any special purpose. In the state of New York these provisions have been adopted with some amplification. The embezzling of property, or the converting of it to his own use, by a clerk or servant of any private person or co-partnership, or by any officer, agent, clerk, or servant of an incorporated company, which shall have come into his possession or under his care, is made punishable in like manner as larceny. It is also enacted that a carrier shall be punishable for embezzling goods in the mass without breaking the package, box, &c., before delivery at the place of destination, in like manner as if he had broken such package, in which latter case he was, as before mentioned, liable at common law. (See 2 Rev. Stat. 678, 679.)

EMBLEMENTS, a term applied to the growing crops of land, when the estate of a tenant for life has expired by the death of the tenant, or when an estate at will has been determined by the lessor. In either case the emblements belong to the tenant or his legal representatives. But when the estate is determined by the lease itself, as when there is an estate for a term of years, the rule is otherwise; for the law does not relieve a man from the consequences of his own voluntary act.

EMBOSSING (Fr. *bosse*, a protuberance), the art of producing raised figures upon plane surfaces, as upon leather for book-binding; upon paper, as stamped envelopes; upon wood in architecture, and bronze, &c., in sculpture. In the two last-named arts, according as the figures are more or less prominent, they are said to be in *alto*, *mezzo*, or *basso rilievo*. Various methods and machines are in use for producing this effect. Leather, paper, and the textile fabrics are embossed by powerful presses, furnished with dies, which give their pattern to the object to be embossed. The press of Messrs. R. Hoe and co. of New York is of very simple and powerful construction. The power is applied by a treadle to straighten a bent arm, as in the old form of the printing press, and the hands of the operator are thus at liberty. Steam is introduced to keep the plate at the temperature

found most suitable. A very ingenious method of embossing wood was introduced in 1824 by Mr. J. Straker of London. The pattern being drawn upon its surface, the parts intended to be in relief are sunk by the application of a blunt steel tool as deep into the wood as they are intended to appear raised above the surface, care being taken not to injure the grain of the wood. The surface is next planed or filed down to the level of the depressed portions. The wood then being placed in water, the compressed parts rise and remain permanently in their original position, and the work is finished by carving as ordinarily practised. A method of softening wood, so that it shall receive impressions from iron moulds into which it is forced, has recently attracted much notice in Paris. The wood is softened by steam, and some ingredients are added to increase its ductility. The bass-relief impressions are said to be sharp and permanent, and to project from 4 to 5 millimetres. The art is named xyloplasty.

EMBRACERY, an attempt to influence a juror by any unlawful consideration, as by private influence or by bribery. This was a criminal offence at common law, though the punishment has been prescribed by different statutes in England. The term is not used in the statutes in the United States, but the offence itself is subject to a penalty. In the state of New York the attempt to corrupt a juror, referee, or arbitrator, by a gift or gratuity, is punishable by imprisonment in the state prison for a term not exceeding 5 years; and so also the receiving of such gift or gratuity by a juror, referee, or arbitrator, is punishable in like manner.

EMBROIDERY, the art of working silk, woollen, cotton, or linen threads with a needle into woollen, muslin, or other fabric. It is of two sorts: embroidery on stuffs, with colored threads, sometimes with the introduction of gold and precious stones, which is done on a loom or frame, chiefly for tents, curtains, housings, &c.; and embroidery on muslin or some delicate fabric, with linen or cotton threads, for the female dress. The latter is worked either by a pattern drawn upon the fabric itself, or by stretching it over a pattern drawn on paper. Tents, which are so much used among the wandering tribes of the East, are often richly adorned by the embroiderer. A tent of a late king of Persia, said to have cost £2,000,000, "was embroidered with burnished gold, studded with precious stones and diamonds, interspersed with rubies and emeralds set with rows of pearls; and there were painted thereon specimens of every created thing, birds and trees, and towns, cities, seas, and continents, beasts and reptiles." The art of embroidery was practised at a very early period, as we find from mention made of it by both sacred and profane writers. Instructions were given to the Hebrews for embroidering the curtains for the tabernacle, with such magnificence that we have reason to suppose that their knowledge of the art was very great. (Exodus xxvi. 1-31;

see also xxxix. 2-8, &c.) It is probable that they acquired it in Egypt, where it was commonly practised. They also made an embroidered coat of fine linen, and a girdle of needle-work, for Aaron. The Babylonians were celebrated for the beauty of their embroidered draperies, but this art seems to have been very generally known among the Asiatic nations. The women of Sidon had acquired great celebrity for their skill in ornamental needle-work long before the Trojan war; and the Grecian women at a later period attained to such a degree of perfection in this accomplishment, that their performances were said to equal the finest paintings. The Phrygians were supposed to be the inventors of this art, and by them it was probably first introduced into Greece. In later times the Moguls were celebrated among all the eastern nations for the splendor of their embroideries, their floors, as well as their walls and couches, being covered with fabrics richly wrought and inlaid with gold and precious stones. At the great exhibition of 1851 the finest specimens of modern embroidery were from Turkey. Embroidery upon canvas with the brilliantly dyed wools of Germany is much practised by the women of America as well as of Europe. The variety and delicate shadings of their colors furnish every tint which can be required for the imitation of the most beautiful objects in nature. The Chinese are at the present day the most indefatigable embroiderers, and their work is always executed with the greatest neatness and regularity; but among the French and Germans the art has been cultivated with wonderful success, and furnishes not merely a pretty occupation for the ladies of those countries, but gives the means of support to a large portion of the population. In England, Scotland, and Ireland, also, it is carried on to a great extent. A machine was invented in 1834, by which one person was able to execute the most difficult and intricate patterns, using 130 needles, all kept in motion at once. It was supposed that this would entirely supersede the old-fashioned method of hand working, but in 1857 one house in Glasgow is said to have employed upward of 30,000 men and women in Scotland and Ireland in the embroidery of muslins, all the work being done by hand, as the machines failed, or proved too expensive. Over 50 firms were engaged in the business, and about £750,000 a year was paid in wages to females in the west of Scotland and in Ireland. From a paper read before the society of arts in London in 1859, it appears that certain difficulties which seemed almost insurmountable in embroidering by machinery had been overcome, and the manufacture was successfully conducted in the establishment of Messrs. Houldsworth of Manchester. The machine was an improvement on that originally contrived by M. Heilmann. A pantagraph was used to copy the pattern to the scale required. Each machine was usually worked by 3 young women and 2 girls. The advantages of its use were the rapidity, accuracy, and ex-

cellence of work in the production of repetitions of the design in borders, flounces, and trimmings for dresses, and the perfect embroidery of a pattern on each side of the fabric, especially useful in window curtains, table covers, and trimmings for upholstery.

EMBRYOLOGY, the study of the mode of formation and development of the animal foetus. The progress of our knowledge on this subject has been marked by several well defined epochs, corresponding with the successive discoveries of as many different investigators. Though many important facts bearing upon embryology were known to the earlier anatomists and physiologists, they were often misinterpreted, and their true relations consequently mistaken. Aristotle and his followers recognized three different modes of generation as occurring among animals, viz.: oviparous, viviparous, and spontaneous generation. Oviparous generation was that form in which the female parent produced eggs, from which the young were hatched, as in most fish, reptiles, and birds. Viviparous generation was that in which the young were discharged alive and fully formed from the body of the parent, as in quadrupeds and the human species; while spontaneous or equivocal generation was that in which certain animals of a low order, such as worms, insects, parasites, maggots, &c., were supposed to be produced spontaneously, without parents, from the soil, the water, or decaying animal and vegetable substances. By the progress of investigation, however, the last mode of generation was shown to be much less frequent in its occurrence than Aristotle had supposed. The first advance in this direction was made about the end of the 17th century, when Redi, an Italian naturalist, studied with care the generation and metamorphoses of insects, showing that many worms and maggots, instead of being produced without parents, were in reality hatched from eggs laid by perfect insects, and that they afterward became transformed, by the process of growth, into similar forms. He also in 1684 showed that most parasitic animals were provided with sexual organs, and produced their young in the same manner with other and larger species. Valisnieri soon afterward (1700) extended the observations of Redi, and applied the same conclusions to other species of insects, and to the parasites inhabiting vegetables. In this way the number of species in which spontaneous generation was regarded as possible or probable gradually diminished, as zoological science became more extended and more accurate; until, in 1837, Schultze demonstrated, by his experiments upon the infusoria, that even these microscopic animalcules are never produced in situations where their germs neither existed before nor could gain access from without. Since then it has been generally acknowledged by physiologists that spontaneous generation is a thing unknown in nature, and that the supposed instances of its occurrence are only cases in which the real process of generation has not been sufficiently investigated. The dis-

inction between oviparous and viviparous animals was also supposed by the ancients to indicate a fundamental difference in their mode of generation. In oviparous animals the eggs were known to be produced by the female, and fecundated by the male, after which the young were hatched from them by incubation. In the viviparous species the embryo was thought to be produced by a mixture of the male sperm with the fluids of the female generative organs; some thinking that the material for the body of the embryo was supplied by the menstrual blood, others that it came from a kind of female sperm, or seminal fluid secreted by the female organs. In 1651 Dr. William Harvey, in his book on generation, first announced the fact that there is no essential difference in the mode of generation between oviparous and viviparous animals, but that "all animals whatsoever, even the viviparous, and man himself not excepted, are produced from ova." But though the truth of this opinion has since been amply confirmed, and its expression (*omne animal ex ovo*) has now passed into a physiological aphorism, yet it was not intended by Harvey precisely in the sense which is now given to it. Harvey never saw the unimpregnated eggs of the quadrupeds, nor did he have any idea of the real structure and function of the ovaries in these animals; and in stating the opinion that the young of the vivipara and of man were produced from eggs, he only meant to say that after sexual intercourse and conception, the first thing produced in the uterus was not the embryo, but rather resembled an egg; and that the embryo was afterward formed from this, by the process of growth. In 1672 Régnier de Graaf showed that the ovaries, in women and in female quadrupeds, were filled with globular vesicles, visible to the eye, similar in appearance to the eggs of birds and fishes. These vesicles he pronounced to be eggs; and the organs in which they were found then took the name of ovaries. A century and a half later (1827) Ch. Ernst von Baer discovered, by the microscope, the real egg of the human female and of the viviparous animals, which is contained in the interior of the vesicles of De Graaf. These eggs were shown to exist in the ovaries of virgin females, as well as of those in whom sexual intercourse had taken place; and it was accordingly demonstrated that, in all animals and in man, the eggs are formed originally in the ovaries of the female, independently of the male; and that these eggs are afterward fecundated, and developed into embryos. Another important discovery remained to complete our knowledge on this part of the subject, viz., that of the spontaneous ripening and discharge of the eggs, in quadrupeds and in man. Négrier, Pouchet, and Bischoff demonstrated (1840-'2-'3) that the eggs of the female, originally produced in the ovaries, ripen and are discharged, independently of sexual intercourse, at certain regular periods; and that the impregnation of these eggs by the male sperm is a subsequent process, taking place after the eggs have

and which form accordingly a continuous membrane, which is called the blastodermic membrane. In eggs which have a large-sized yolk, as those of the birds, lizards, and turtles, the formation of the blastodermic membrane begins at a particular spot on the surface of the vitellus, termed the *blastopore*, and thence spreads in every direction, so as to enclose gradually all the rest of the yolk. But in those which are of minute size, as in quadrupeds and the human species, the whole vitellus is converted into the blastodermic membrane, which after its formation encloses only a small cavity filled with transparent, watery fluid. The blastodermic membrane then becomes variously altered and developed in different parts, so as to form the various organs and tissues of the embryo. A line or furrow first shows itself, in the thickest and most condensed portion, known as the primitive trace. This indicates the future situation of the spinal column; and the different parts of the vertebrae gradually grow around it, forming a chain of cartilaginous rings, with transverse and oblique processes, which envelope the primitive trace or furrow, and convert it into a closed canal, large and rounded at the anterior extremity, or head, but narrow and pointed at the posterior extremity, or tail. In this canal the brain and spinal cord are formed

swells up into a tremulous gelatinous mass, which floats near the surface, with the eggs imbedded in its substance. The formation of the embryo then goes on as above described, and the young animal, at first curled up in the interior of the vitelline membrane, soon ruptures it and effects its escape. The body is at this time of an elongated form, terminating behind in a narrow, compressed tail. The integument is covered with vibrating cilia, which produce a constant current of fresh water over the surface of the body. Respiration is performed by gills, situated at the sides of the neck, which are at first exposed, but afterward become covered by a fold of integument. The muscular system is very feeble, and the young animal remains nearly motionless, attached by the mouth to the gelatinous matter around the eggs, upon which he feeds for several days. As he increases in size and becomes stronger, he abandons the spawn and swims about freely in the water, feeding upon the juices and tissues of aquatic vegetables. The cilia with which the body was covered disappear. The alimentary canal is at this time very long in proportion to the size of the whole body, being coiled up in the abdomen in a spiral form. During the summer lungs are developed in the interior, and the young tadpole frequently comes to the surface to take in air. But the

gills also continue, and are still the most active organs of respiration. Toward the end of the season anterior and posterior extremities or limbs begin to grow; the posterior sprouting externally from each side, in the neighborhood of the anus; the anterior remaining concealed under the integument, just below the situation of the gills. The tadpole passes the winter in this transition state. The next spring the lungs increase in size, and the gills become less active as organs of respiration. The anterior extremities are liberated from their confinement by a rupture of the integument which covered them, and both anterior and posterior grow rapidly in size and strength. The tadpole at this time, therefore, has both fore and hind legs and a tail. The tail, early in the summer, becomes atrophied; and finally withers and disappears altogether; while the limbs, and especially the hind legs, grow to a disproportionate size. At the same time, the lungs attaining their full development, and the gills finally disappearing, the tadpole is thus converted into a perfect frog, capable of living and moving upon the land as well as in the water. The tadpole swims by the tail and breathes by gills, while the frog swims by the legs and breathes by lungs. Simultaneously with these changes, the alimentary canal becomes very much shorter in proportion to the rest of the body, and the frog becomes carnivorous in its habits, living principally upon insects, which he is enabled to capture by the great development of his muscular system, and the rapidity and suddenness of his movements. —The process of development of the embryo consists, accordingly, in the successive formation and disappearance of different organs which are adapted to different modes of life. When these changes take place after the young embryo has left the egg, as in the case of the frog, and produce marked alterations in the external form of the body, they are termed transformations or metamorphoses. Thus the egg of the butterfly, when first hatched, produces a caterpillar, or larva—an animal with a worm-like body, sluggish crawling movements, and no sexual apparatus, but furnished with largely developed digestive organs and a voracious appetite. This condition is succeeded by the pupa state, in which the animal changes its skin, losing the legs and bristles which were its locomotory organs, and becomes motionless, nearly insensible to external impressions, and stops feeding altogether. During this period another integument grows underneath the old, with new legs and wings; and when the skin is again changed, the animal appears as a perfect insect, or imago, capable of rapid and sustained flight, ornamented with brilliant colors, provided with different sensory and digestive organs and a well developed sexual apparatus.—In those instances where the hatching of the egg is a longer process, similar changes to the above take place while the embryo is still retained in its interior. At the same time certain other organs are formed in addition, which either disappear before the time

of hatching, or are thrown off when the young animal leaves the egg. With turtles, for example, the eggs, consisting of the vitellus, albumen, and shell, are deposited in an excavation in the earth or sand, and allowed to hatch in these situations. In birds, they are placed usually in nests, formed of twigs, leaves, and fibres, and there kept constantly warmed and protected by contact with the body of the female parent. This process is termed incubation, and may be imitated artificially by keeping the eggs at a temperature of 104° F. and providing for the regular supply of fresh air and a proper regulation of the atmospheric moisture. During incubation the eggs of the common fowl lose 12 per cent. of their weight, of which 11 per cent. is due to the exhalation of moisture. They also absorb oxygen and exhale carbonic acid. The segmentation of the vitellus and formation of the blastodermic membrane, and of the organs of the embryo, take place for the most part according to the plan already described, but variations present themselves which make the process more complicated. The vitellus, for example, instead of being entirely surrounded by the abdominal walls, is divided into two portions by a constriction situated about its middle. One of these portions remains outside the abdomen of the embryo, though still connected with it by a narrow neck, and by blood vessels which ramify upon its surface. This sac, containing a portion of the vitellus, is called the umbilical vesicle. It supplies the embryo with nourishment during the whole period of incubation; for immediately after the egg is laid the albumen, which is at first gelatinous in consistency, begins to liquefy near the upper surface, and the liquefied portions are immediately absorbed into the yolk. The yolk, therefore, grows larger and more fluid than before, while the albumen diminishes in quantity, and loses its watery portions. The blood vessels of the embryo, ramifying over the surface of the vitellus and the umbilical vesicle, in their turn absorb the nutritious fluids from it, and convey them into the interior of the body, to be used in the formation of the tissues. At the end of incubation the albumen has disappeared and the umbilical vesicle has much diminished in size, while the body of the chick has increased, at the expense of both; but the umbilical vesicle, containing the remains of the yolk, still exists, and is enclosed within the abdominal walls when the chick leaves the egg. In quadrupeds and the human species the umbilical vesicle is much smaller in proportion to the body, and less important in function, than in birds and the scaly reptiles. In the human embryo, the umbilical vesicle, always very small, disappears soon after the end of the third month of gestation. In the egg of the fowl, certain accessory membranes or envelopes begin to grow around the embryo at an early period. The first of these is the amnion, which is formed by a double fold of the blastodermic membrane, rising up about the edges of the body of the embryo, so as to surround it by a

kind of circumvallation, or embankment. By continued growth these folds at last approach each other and meet over the back of the embryo, forming by their union and adhesion an enclosing membrane, or sac, which is the amnion. The amnion, therefore, is a membranous envelope, which is closed over the back of the embryo, but which remains open in front of the abdomen. About the same time a vascular, membranous diverticulum grows out from the alimentary canal, near its posterior extremity, and emerging from the open part of the abdomen turns upward over the back of the embryo, outside the amnion, and just inside the shell membranes. This vascular outgrowth is the allantois. It increases rapidly in size, growing upward and downward in every direction, until it finally envelopes completely the body of the embryo and the umbilical vesicle, taking the place of the albumen as it is gradually absorbed, and lining the whole interior of the egg shell with a continuous vascular membrane. The function of the allantois is principally to aerate the blood of the embryo, by bringing it into close contact with the porous egg shell, and thus allowing the absorption of oxygen and the exhalation of carbonic acid and watery vapor. Toward the latter period of incubation, the allantois becomes very closely adherent to the egg shell, and the shell itself grows thinner, more porous, and more fragile; whence it is believed that the allantois also serves to absorb calcareous matter from the shell, which it conveys into the interior of the body, to be used in the formation of the bones, the ossification of which takes place about this period. When the chick is sufficiently developed to leave the egg, usually at the end of the 21st day, by a sudden movement it strikes its bill through the end of the attenuated and brittle egg shell, and by inhaling the air and continuing its struggles, finally extricates itself from the cavity of the shell, leaving the allantois adherent to its internal surface. The bloodvessels of the allantois are torn off at the umbilicus, which afterward closes up, and unites by a permanent cicatrix. —Another important change which takes place in the development of birds and quadrupeds, in addition to those presented by frogs and fishes, is in the formation of the urinary apparatus. In fishes and batrachians the urinary organs are two long glandular bodies situated on each side the spinal column, which are known as the Wolffian bodies, and which remain permanent throughout the life of the animal, no true kidneys ever being produced. But in birds and quadrupeds, the Wolffian bodies, which are at first very large and important organs, disappear during the progress of embryonic development, while the kidneys are formed at the same time, and gradually take their place as urinary organs. The kidneys are accordingly substituted for the Wolffian bodies in these instances, very much as lungs are substituted for gills in the development of the frog.—In many species of quadrupeds the allantois attains a large

size, and performs a very important function, during extra-uterine life. In the ruminating animals, cows, sheep, goat, deer, &c., it forms an elongated sac, taking the form of the uterine cavity, and lying in close contact with the lining membrane of the uterus. The cavity of this sac communicates with the cavity of the posterior part of the intestine, from which it was originally developed, and receives the secretion of the Wolffian bodies, and afterward of the kidneys. Its exterior is covered with a large number (60 to 80) of tufted vascular prominences, which are entangled with similar elevations of the uterine mucous membrane, called cotyledons; and the blood of the embryo, while circulating through these bodies, absorbs from the maternal vessels the materials requisite for its nutrition. In the pig, the allantois is nearly smooth on its external surface, merely presenting transverse folds and ridges, which lie in contact with similar inequalities of the uterine mucous membrane. In the carnivorous animals its middle portion is shaggy and vascular, and entangled with the bloodvessels of the uterus, while its two extremities are smooth and unattached. In the human embryo, the amnion is formed in the same manner as already described; but the allantois, instead of constituting a hollow sac, with a cavity containing fluid and communicating with the intestine, spreads out into a continuous flattened membrane, the two layers of which are in contact with each other and adherent, leaving consequently no cavity between them. It extends, however, quite round the foetus, enveloping it in a continuous vascular membrane, which here takes the name of the chorion. The chorion is, accordingly, the same thing in the human species as the allantois in the lower animals, except that its cavity is obliterated by the adhesion of its walls. It is covered uniformly, at an early date, with tufted villousities, which become entangled with the mucous membrane of the uterus. But during the 3d month it begins to grow smooth over the greater portion of its surface, while at a certain part the villous tufts grow more rapidly than before, until they are finally converted into a thick vascular, spongy, and velvety mass of villousities, which penetrate into the uterine mucous membrane, and become adherent to its bloodvessels. This organ is then termed the placenta; and from that time forward it serves the foetus as an organ of absorption and nourishment, its bloodvessels imbibing from the circulation of the mother the albuminous fluids which it requires for growth and nutrition.—The amnion in the human species is at an early period so arranged that it closely invests the body of the embryo, while between it and the chorion there is interposed a thick layer of soft gelatinous material. During the 2d and 3d months the cavity of the amnion enlarges, by the accumulation of a watery and albuminous fluid (the amniotic fluid) in its interior, while the gelatinous matter between it and the chorion is gradually absorbed and disappears, in order to make way

for its expansion. By this enlargement the amnion approaches nearer the internal surface of the chorion, and by the beginning of the 5th month the two membranes come in contact with each other. By this means the foetus becomes enclosed in a large cavity (the amniotic cavity), filled with fluid, so that a free space is allowed for the movements of the foetal limbs. These movements begin to be perceived about the 5th month, at which time quickening is said to take place. They afterward become more strongly pronounced, and before birth are frequently very active. These movements are also favored by the formation and growth of the umbilical cord. The blood vessels of the foetus, termed the umbilical vessels, which pass out from the abdomen to the placenta and the chorion, become much elongated, and at the same time covered with a deposit of hard gelatinous matter, the whole being covered by a prolongation of the membrane of the amnion. This bundle of vessels, covered with the above investments, is termed the umbilical cord. It grows very long, and also becomes spirally twisted upon its own axis, usually in a direction from right to left. There are, in the latter periods of gestation, two umbilical arteries, carrying the blood of the foetus outward to the placenta, and one umbilical vein, in which it is returned to the body and the internal venous system.—The formation of the blood and blood vessels in the embryo takes place at a very early period. Soon after the production of the blastodermic membrane, some of the cells of which it is composed break down, and liquefy in such a manner as to leave irregular spaces, or canals, which inosculate with each other by frequent communications. These canals are destined afterward to become the blood vessels, the structure of which is gradually perfected by the growth of fibrous tissue in their walls, and their complete separation from the neighboring parts. In the interior of these canals, or imperfectly formed blood vessels, there is to be seen at first only a transparent, colorless fluid, holding in suspension a few large, roundish, nucleated cells, which move sluggishly to and fro, as the current of the circulating fluid begins to be established. These cells do not differ much at this period from those which constitute the general mass of the neighboring tissues; but soon afterward they begin to be modified in their appearance, and converted into true blood globules. Their surface becomes smooth, and a reddish coloring matter is produced in their interior, which gives them a tinge similar to that of the red globules of the blood in the adult condition. The red blood globules of the foetus, however, still differ in several important particulars from those of the adult. They are considerably larger and more globular in shape, and have also a very distinct nucleus, which is wanting in the blood globules of the adult, at least in the quadrupeds. They increase in numbers also, at this time, by spontaneous division, one globule becoming divided into two, which separate from each other

and afterward become themselves divided in a similar manner. In this way the quantity of the blood globules is very rapidly increased, and they soon become also still further altered in form and structure. They diminish in size, become in the human subject and the quadruped flattened and biconcave in form, and finally the nucleus disappears. These changes are all effected during foetal life, and for the most part during the early months, so that at the time of birth the blood globules have already the characteristics which distinguish them in adult life. The multiplication of the blood globules by subdivision is a process which takes place only in the embryo. The perfectly formed blood globules increase in number in some other way, probably by the isolated production and growth of new cells.—At the time of birth the foetal membranes (amnion and chorion) are ruptured, and the foetus escapes. The umbilical cord being at the same time divided and tied, the portion still connected with the foetus soon shrivels and separates by spontaneous ulceration, while the spot at which it was attached heals in a few days, leaving a cicatrix on the middle of the abdomen, which is permanent throughout life, and which is called the umbilicus.—The limbs grow, by a kind of budding or sprouting process, from the sides of the body. They are at first mere rounded eminences, without distinction of parts or articulations; but they subsequently become successively divided into fingers and toes, and the different joints of the arm and leg. The upper extremities, during the greater part of foetal life, are larger than the lower, but afterward the lower extremities and the pelvis grow faster than the arms and shoulders, and finally become after birth much the larger of the two. The lungs are small and solid in texture before birth, but immediately afterward they expand by the inhalation of air, and receive a much larger supply of blood than before. On the other hand, the liver is much larger in proportion to the rest of the body at an early period than subsequently. In some animals it amounts, during the first part of foetal life, to 12 per cent. of the entire weight of the body, and is reduced to 8 or 4 per cent. at the time of birth. In the human subject it is equal at birth to 8½ per cent. of the entire weight, but is reduced in the adult to less than 3 per cent. Great changes take place also during foetal life in the anatomy of the heart and circulatory system, as well as in the relative size and development of nearly all the organs in the body. These changes continue to take place after birth, though less rapidly than before, and the entire process of development is not regarded as complete until the individual has reached the adult condition.—A very singular modification of the above process of embryonic development among the mammals occurs in the marsupial animals, of which the American opossum (*Didelphis virginiana*) is a representative. In these animals the eggs are impregnated and the formation of the embryo commenced in the usual way; but after remain-

ing for a comparatively short time in the uterus, and while their development is still very incomplete, the embryos are discharged from the generative passages, and are immediately afterward found attached by the mouth to the teats of the parent. They are then less than half an inch in length, and quite gelatinous and embryonic in appearance. They are protected by a double fold of the integument of the abdomen, which forms a kind of pouch, surrounding the teats, and serving to enclose the young and helpless embryos. They remain in this situation during the completion of their development, continuing attached for the most part to the teats, from which they derive nourishment; and even after they have become capable of running about by themselves, they still, upon an alarm, take refuge for a time in the pouch as before. It is not known how the young embryos, when expelled from the uterus, find their way into the external pouch, so as to reach the teats, for, notwithstanding many attempts have been made to ascertain this point, the animal is so secret in her habits at the time of delivery, that they have been thus far entirely unsuccessful.—Among invertebrate animals the egg is constituted, as a general thing, in nearly the same way as in vertebrata, and its impregnation takes place also in a similar manner. The segmentation of the yolk goes on by repeated subdivisions, until the whole vitellus is converted into a mulberry-shaped mass, out of which the embryo is formed. While, however, in the vertebrate animals, the embryo always lies with its belly upon the surface of the yolk, in some of the invertebrates, as the articulatæ (insects, spiders, crustaceans), the back of the embryo is in contact with the yolk, and the closing up or union of the two sides of the body takes place along the dorsal line, instead of the abdominal. In many mollusks, as for example in snails, the embryo, soon after the commencement of its formation, begins to rotate slowly in the interior of the vitelline sac; and this rotation continues more or less rapid until the hatching of the egg. In the invertebrate classes the metamorphoses or transformations of the young animal are more frequent and more striking than in vertebrata. In many of them the young animal, when first hatched from the egg, is entirely unlike its parent in structure, external appearance, and habits of life. In the class of insects many of these transformations are well known, and have always attracted the attention of the curious. Frequently the young animal, in passing through several successive transformations in which he is adapted to different modes of life, necessarily changes his habitation; and being found accordingly in totally different localities, and presenting at successive intervals corresponding differences of organization, the same embryo at different ages is often mistaken by the ignorant for an entirely distinct species of animal. These changes of habitation, occurring in the course of embryonic development, are termed migrations. They are often very marked in parasitic animals. Thus the

tænia, or tapeworm, inhabiting the small intestines of certain animals, such as the dog, cat, &c., produces an egg containing a small globular embryo, armed with certain hard spikes, or curved prominences, capable of being moved by muscular fibres inserted into their base. The portion of the tapeworm in which these eggs are contained, known as the proglottis, is discharged from the intestine of the first animal, and the eggs, becoming mixed with vegetable matter, are devoured by animals belonging to other species, as for example the pig. Either in the process of mastication, or by the action of the digestive fluids of the stomach, the external envelope of the egg is destroyed, and the embryo set free. By means of its movable projecting spines, the embryo then makes its way through the walls of the stomach or intestine into the neighboring organs, and passing into the cavity of the blood vessels, is often transported by the current of the blood to distant regions of the body. Here, becoming arrested, it is temporarily fixed in place by the consolidation of the tissues round it, and becomes enlarged by the imbibition of fluid, assuming a vesicular form. A portion of this vesicle becomes inverted, and at the bottom of the inverted part a head is produced, upon which there are formed four muscular disks, or suckers, and a circle of calcareous spines or hooks, different from those present at an earlier period, which are thrown off and lost. In this state the animal receives the name of *scolex*, or *cysticercus*. It remains in that condition till the death of the animal whose tissues it inhabits, when being devoured with the flesh by an animal belonging to the first species, it passes into the intestine of the latter, and there becomes developed into the complete tapeworm, or *strobila*, similar to that from which its embryo was first produced. The same animal is accordingly a parasite in different organs, and even in different species, at different periods of its development. Some of the invertebrata are parasitic at one stage of their existence, and lead an independent life at another. Such are the small crustacea which infest the bodies and gills of certain fish. In the family of *æstridea*, or bot flies, the eggs are deposited by the female insect, and attached to the hairs of horses, cattle, &c.; from which situation, after the embryo has become partly developed, they are detached in some instances (as in *æstrus equi*) by licking, and swallowed into the stomach. Here the larva is set free, and attaches itself to the mucous membrane of the stomach, nourishing itself upon the fluids obtained from this source, and gradually increasing in size. After a certain period the larva lets go its hold, passes through the intestine, is discharged with the fæces, and assuming the pupa state, is finally transformed into the perfect insect. The process of embryonic development is accordingly a succession of changes, in which the structure and organization of the young animal are adapted to different modes of existence, and in which different organs and

apparatuses, successively appearing and disappearing, replace each other in the progress of growth, and give rise to the appearance of transformations, which affect the body as a whole.—See Harvey, *Exercitationes Anatomicae de Generatione Animalium* (London, 1651; Sydenham edition, London, 1847); Spallanzani, *Expériences pour servir à l'histoire de la génération* (Genève, 1786); Von Baer, *De Ovi Mammalium et Hominis Genesi Epistola* (Leipsic, 1827); Valentin, *Handbuch der Entwicklungsgeschichte des Menschen* (Berlin, 1835); Coste, *Recherches sur la génération des mammifères* (Paris, 1834); *Embryogénie comparée* (Paris, 1837); *Histoire générale et particulière du développement des corps organisés* (Paris, 1847, '49, '53); Pouchet, *Théorie positive de la fécondation des mammifères* (Paris, 1842); *Théorie positive de l'ovulation spontanée et de la fécondation des mammifères et de l'espèce humaine* (Paris, 1847); Bischoff, *Traité du développement de l'homme et des mammifères, sur la maturation et la chute périodique* (Paris, 1843); *De l'œuf de l'homme et des mammifères, indépendamment de la fécondation* (*Annales des sciences naturelles*, Aug. 1844); *Entwicklungsgeschichte des Meerschweinchens* (Giessen, 1852); Rathke, *Ueber die Entwicklung der Schildkröten* (Brunswick, 1848); H. EMBURY, EMMA CATHARINE, an American authoress, born in New York. She is the daughter of Dr. James R. Manley of that city, and was married to Mr. Daniel Embury in 1828. In the same year she published "Guido and other Poems." Since her marriage she has written more prose than verse, and her tales, like her poems, have been originally published in the columns of the periodical press. Of these some have appeared in a collected form, under the titles of "The Blind Girl and other Tales," "Glimpses of Home Life," and "Pictures of Early Life." In 1845 she supplied the letterpress, both prose and verse, to an illustrated gift book entitled "Nature's Gems, or American Wild Flowers," and in the succeeding year published a collection of poems called "Love's Token Flowers." Her last work is "The Waldorf Family, or Grandfather's Legends" (1848), a fairy tale of Brittany, partly a translation and partly original.

EMDEN, or EMBDEN, a seaport town of Hanover, in the province of Aurich (the former principality of East Friesland), situated a little below the outfall of the river Ems into the Dollart estuary; pop. 13,000. The harbor is shallow, but the roadstead is capable of accommodating large vessels. Canals intersect the town in various directions; one connects it with the town of Aurich, and another (opened since 1846, at a cost of \$230,000) with the river Ems. Another canal is now in course of

construction to connect the town with the deep waters of the Dollart. It is also to be protected by a high and strong embankment against the incursions of this estuary, from which it has frequently suffered. Although the town has declined in population and prosperity, it continues to be a commercial place of considerable importance. About 400 vessels enter and leave the port annually, and ship-building is extensively carried on. Emden is of very ancient origin, and resembles more a Dutch than a German town. In the present century it has passed through the hands of Prussia, Holland, and France, and came to Hanover in 1815.

EMERALD (Sp. *esmeralda*; Gr. *σμεραρα*, to shine), a name given to the finest crystals of the mineral species beryl, transparent and of rich green colors derived from oxide of chrome, which is present in the proportion of less than one per cent. (See BERYL for description of the species.) It is found in metamorphic rocks, the granites, hornblende rocks, dolomites, &c. The first known come from the vicinity of Bogota, the capital of New Granada, in South America, where they are said to be found in veins in a black limestone. It is from this region that the celebrated crystal in the cabinet of the duke of Devonshire is said to have been obtained. The Peruvian emeralds were famous from the time of the conquest of that country by Pizarro. They were obtained in the barren district of Atacama, and worked by the native artists with the skill of the modern lapidary. To this day a river and a village of Ecuador are known by the name of Esmeraldas from the abundance of emeralds formerly found in that region. Mexico, at the same early period, had produced crystals of rare beauty, which were no less appreciated and highly valued by the rulers of the Aztecs than were those of Peru by its incas. When Cortes on his return to Europe preferred, in the disposal of 5 of these magnificent jewels, his youthful bride to the queen of Charles V., a feeling of estrangement is thought to have been produced in the royal bosom, which had an unfavorable influence on the future fortunes of the conqueror. For one of these precious stones some Genoese merchants are said to have offered Cortes 40,000 ducats. They had been cut by the exquisite workmanship of the Aztecs, one in the form of a rose; the second in the form of a horn; the third like a fish, with eyes of gold; the fourth was like a little bell, with a fine pearl for the tongue. The fifth, which was the most valuable, was a small cup with a foot of gold, and with 4 little chains of the same metal attached to a large pearl as a button. From these sources were probably obtained the magnificent emeralds now in the royal collection at Madrid, some of which are stated to be as large as those of the duke of Devonshire, and of the finest water. The emerald has long been highly esteemed, ranking in value next to the diamond and the ruby. Pliny states that in his time those of considerable size, which were free from defects, were sold at exor-

mous prices. The color of the emerald is a peculiar shade of green, different from that of any other precious stone, and is called by the name of emerald green. It has different shades, some of verdigris or grass green, and some of a paler hue. They all appear best by daylight, and to retain their effect by candle light they require to be set with small diamonds or pearls. Emeralds are generally cut in the form of a square table, with bevelled edges, the lower surface being cut into facets, parallel to their sides. Beudant, in his *Minéralogie*, gives the value of emeralds of fine colors, and free from flaws, as follows: one of 4 grains, 100 to 120 francs; of 8 grains, 240 francs; of 15 grains, as high as 1,500 francs; and he cites a fine stone of 24 grains which was sold at 2,400 francs.

EMERSON, GEORGE BARRELL, an American educator, born in Kennebunk, York co., Maine, Sept. 12, 1797. He was graduated at Harvard college in 1817, and soon after took charge of an academy in Lancaster, Mass., having for some years previously employed portions of his college terms and vacations in teaching district schools in Maine and Massachusetts. Between 1819 and 1821 was the tutor in mathematics and natural philosophy in Harvard college, and in 1821 was chosen principal of the English high school for boys then recently established in Boston. In 1823 he opened a private school for girls in the same city, which he conducted until 1855, when he retired from professional life. He wrote the 2d part of the "School and Schoolmaster," of which the 1st part was written by Bishop Potter of Pennsylvania, and which was distributed by private munificence among the school districts of Massachusetts and New York; and is the author of a number of lectures on education, and of articles contributed to the periodical press. He was for many years president of the Boston society of natural history, and was appointed by Gov. Everett chairman of the commissioners for the zoological and botanical survey of Massachusetts, in which capacity he published a "Report of the Trees and Shrubs growing naturally in the Forests of Massachusetts" (Boston, 1846).

EMERSON, RALPH WALDO, an American poet and essayist, born in Boston, May 25, 1803. He is the son of the Rev. William Emerson, pastor of the 1st church in that city; in his 8th year, on the death of his father, he was sent to one of the public grammar schools, and was soon qualified to enter the Latin school. Here his first attempts in literary composition were made, consisting not merely of the ordinary exercises by which boys are drearily inducted into the mysteries of rhetoric, but of original poems recited at exhibitions of the school. In 1817 he entered Harvard college, and was graduated in August, 1821. He does not appear to have held a high rank in his class, though the records show that he twice received a Bowdoin prize for dissertations, and once a Boylston prize for declamation. He was also the poet of his class on "class day." While at the univer-

sity he made more use of the library than is common among students, and when graduated was distinguished among his classmates for his knowledge of general literature. For 5 years after leaving college he was engaged in teaching school. In 1826 he was "approbated to preach" by the Middlesex association of ministers, but his health at this time failing, he spent the winter in South Carolina and Florida. In March, 1829, he was ordained as colleague of Henry Ware, at the 2d Unitarian church of Boston. He belongs to a clerical race. For 8 generations, reckoning back to his ancestor Peter Bulkley, one of the founders of Concord, Mass., there had always been a clergyman in the family, either on the paternal or maternal side. He was the 8th, in orderly succession, of this consecutive line of ministers. In Sept. 1830, he was married to Ellen Louisa Tucker of Boston, who died in Feb. 1831. In 1832 he asked and received a dismission from the 2d church, on account of differences of opinion between himself and the church, touching the Lord's supper. From this period we may date that impatience with fixed forms of belief, and that instinctive suspicion of every thing having the faintest appearance of limiting his intellectual freedom, which were afterward so conspicuous in his writings, and which have sometimes been carried so far as to give a dash of wilfulness and eccentricity to his most austere honest thinking. In Dec. 1832, he sailed for Europe, where he remained nearly a year. On his return in the winter of 1833-'4 he began that career as a lecturer, in which he has since gained so much distinction, with a discourse before the Boston mechanics' institute, on the somewhat unpromising subject of "Water." Three others followed, two on Italy, descriptive of his recent tour in that country, and the last on the "Relation of Man to the Globe." In 1834 he delivered in Boston a series of biographical lectures on Michel Angelo, Milton, Luther, George Fox, and Edmund Burke, the first two of which were afterward published in the "North American Review." In this year also he read at Cambridge a poem before the Phi Beta Kappa society. In 1835 he fixed his residence at Concord, Mass., where he has since lived. In Sept. 1835, he married Lidian Jackson, daughter of Charles Jackson of Plymouth. During the winter he delivered in Boston a course of 10 lectures on English literature. These were followed, in 1836, by 12 lectures on the philosophy of history; in 1837, by 10 lectures on human culture; in 1838, by 10 lectures on human life; in 1839, by 10 lectures on the present age; in 1841, by 7 lectures on the times; and since that period he has delivered in Boston 5 or 6 courses of lectures, which are still among his unpublished writings. Of his printed works, a small volume entitled "Nature" (published in 1836), an oration before the Phi Beta Kappa society, with the general title of the "American Scholar" (1837), an address to the senior class of the Cambridge divinity school (1836), and the "Method of

Nature" (1841), contained the most prominent peculiarities of his scheme of idealism, and by their freshness and depth of thought and compact beauty of expression, allured many readers into disciples. In 1840 the school of New England transcendentalists was sufficiently large to demand an organ; and a quarterly periodical, called the "Dial," was started, with Miss Margaret Fuller as editor, assisted by A. B. Alcott, William H. Channing, Mr. Emerson, Theodore Parker, George Ripley, and others. It was published for 4 years, and during the last 2 years of its existence it was under the editorship of Mr. Emerson. In 1841 the first series of his "Essays" was published. The author might proudly say of these, as Bacon said of his own, "that their matter could not be found in books." It is probable that they would have been at once widely welcomed as a positive addition to literature, had it not been for some startling paradoxes and audacious statements, which, while they were in direct conflict with the theological beliefs of the people, were supported neither by facts nor arguments, but rested on the simple testimony of the author's individual consciousness. In 1844 a second series of essays was published, evincing, as compared with the first, equal brevity and beauty of expression. In 1846 he collected and published his poems. The next year he visited England for the purpose of fulfilling an engagement to deliver a series of lectures before a union of mechanics' institutes and other societies. In 1849 he collected in one volume his "Nature" and 9 lectures and college addresses, which had been previously issued in pamphlet form, or printed in the "Dial." In 1850, "Representative Men," a series of masterly mental portraits, with some of the features overcharged, was published. To the "Memoirs of Margaret Fuller Ossoli," which appeared in 1852, he contributed some admirable interpretative criticism. In 1856 he published "English Traits," a work in which he seizes and emphasizes the characteristics of the English mind and people. Mr. Emerson has also delivered many unpublished addresses on slavery, woman's rights, and other topics of public interest; and he has been one of the most prominent of the lecturers who address the lyceums of the country.—As a writer, Mr. Emerson is distinguished for a singular union of poetic imagination with practical acuteness. His vision takes a wide sweep in the realms of the ideal; but is no less firm and penetrating in the sphere of facts. His observations on society, on manners, on character, on institutions, are stamped with rare sagacity, indicating a familiar knowledge of the homely phases of life, which are seldom viewed in their poetical relations. One side of his wisdom is worldly wisdom. The brilliant transcendentalist is evidently a man not easy to be deceived in matters pertaining to the ordinary course of human affairs. His common sense shrewdness is vivified by a pervasive wit. With him, however, wit is not an end, but a means, and usually

employed for the detection of pretence and impostures. / Mr. Emerson's practical understanding is sometimes underrated from the fact that he never groups his thoughts by the methods of logic. He gives few reasons, even when he is most reasonable. He does not prove, but announces, aiming directly at the intelligence of his readers, without striving to extract a reluctant assent by force of argument. Insight, not reasoning, is his process. The bent of his mind is to ideal laws, which are perceived by the intuitive faculty, and are beyond the province of dialectics. Equally conspicuous is his tendency to embody ideas in the forms of imagination. No spiritual abstraction is so evanescent but he thus transforms it into a concrete reality. He seldom indulges in the expression of sentiment, and in his nature emotion seems to be less the product of the heart than of the brain. Mr. Emerson's style is in the nicest harmony with the character of his thought. It is condensed almost to abruptness. Occasionally he purchases compression at the expense of clearness, and his merits as a writer consist rather in the choice of words than in the connection of sentences, though his diction is vitalized by the presence of a powerful creative element. His thought dictates his word, stamps it with its own peculiar quality, and converts it from a fleeting sound into a solid fact. The singular beauty and intense life and significance of his language demonstrate that he has not only something to say, but knows exactly how to say it. Fluency, however, is out of the question in a style which combines such austere economy of words with the determination to load every word with vital meaning. But the great characteristic of Mr. Emerson's intellect is the perception and sentiment of beauty. So strong is this, that he accepts nothing in life that is morbid, uncomely, haggard, or ghastly. The fact that an opinion depresses, instead of invigorating, is with him a sufficient reason for its rejection. His observation, his wit, his reason, his imagination, his style, all obey the controlling sense of beauty, which is at the heart of his nature, and instinctively avoid the ugly and the base. Those portions of Mr. Emerson's writings which relate to philosophy and religion may be considered as fragmentary contributions to the "Philosophy of the Infinite." He has no system, and indeed system in his mind is associated with charlatanism. His largest generalization is "Existence." On this inscrutable theme, his conceptions vary with his moods and experience. Sometimes it seems to be man who parts with his personality in being united to God; sometimes it seems to be God who is impersonal, and who comes to personality only in man; and the real obscurity or vacillation of his metaphysical ideas is increased by the vivid and positive concrete forms in which they are successively clothed. Generally, the divine Being is felt or conceived as a life-imparting influence divinizing nature and man, and as identical with both. He adores the Spirit of God rather than God, the

rays of the sun rather than the sun, and does not appear to give sufficient prominence to the obvious principle that the individuality of the Divine Nature, being an infinite individuality, may include infinite expansiveness and infinite variety of working in infinite self-consciousness; and that the appearance of impersonality comes from the conception of personality under finite human limitations.

EMERY, a mineral substance usually described as a variety of corundum, but really a mechanical mixture of this mineral with oxide of iron, so intimately associated that the smallest fragment commonly exhibits the two together. In some instances, when separated into different portions by washing with oil, fine crystals of corundum have been detected by the microscope. Its extreme hardness, derived from the corundum, and the ease with which it is obtained in large quantities, have led to its extensive use in the arts, for grinding and polishing hard stones, metals, and glass. The localities from which it is obtained in the Grecian archipelago, and in the vicinity of Smyrna and Ephesus in Asia Minor, were probably some of them known to the ancient Greeks and Romans, as the use of a substance of this nature seems to have been required by the lapidaries of Magnesia, Ephesus, Tralles, and Tyre. In later times the island of Naxos in the archipelago has furnished all the supplies of commerce, the mineral being shipped from the port of Smyrna, and known by the name of Smyrna emery. From 1835 to 1846 the trade in emery was a monopoly granted by the Greek government to an English merchant, who so regulated the supply as to raise the price from its former rate of \$40 a ton to about \$140. This monopoly was broken up and the whole trade changed in consequence of the discoveries of Dr. J. Lawrence Smith of the United States, who in the course of his explorations in the service of the Porte discovered in 1847 a number of localities of the mineral belonging both to the Turkish and Greek governments. By an arrangement with the former, operations were commenced in the same year at some of the localities and afterward extended to others, so that the price has since been reduced to \$50 per ton. At the mountain of Gumuch-dagh, 12 m. E. of the ruins of Ephesus, Dr. Smith found the emery upon the summit scattered about in loose pieces of all sizes, up to masses of several tons weight. The rock to which it belonged was a bluish metamorphic marble, reposing upon mica slate and gneiss. In this rock the mineral was found in nodules, and in amorphous masses, some of which were several yards in length and breadth, and of the weight of 30 to 40 tons. The structure of this rock is compact and tolerably regular, but the surface presents a granular appearance. Unless traversed by fissures, the rock is broken with great difficulty, and attempts to drill it are made in vain from its wear upon the tools. As the transportation from the quarries is only on the backs of camels or horses, many

of the heavier masses are necessarily left behind. Some of the blocks, however, yield to the hammers after being exposed for some hours to the action of fire. The color of the powder varies from dark gray to black; but its shade has no relation to its hardness, and is consequently no index of the value of the article. The relative degrees of hardness of different samples were determined by Dr. Smith by collecting the powder just coarse enough to pass through a sieve of 400 holes to the inch, and with weighed samples of this rubbing little test plates of glass till they ceased to be further reduced. The rubber was the smooth bottom surface of an agate mortar. The loss in weight experienced by the glass plates gave the relative values of the samples of emery. On this plan Dr. Smith prepared a table exhibiting the different degrees of hardness; and making use of sapphire of Ceylon as the standard of comparison, the hardness of which he called 100, and the effective wear of which upon glass was equal to about $\frac{1}{3}$ of its own weight, that of the best emery was about $\frac{1}{4}$ of its weight. This table, to which were appended the results of the analyses of many samples of the mineral made by Dr. Smith, was published in the elaborate articles he furnished to the "American Journal of Science," 2d series, vols. x. and xi. The hardness of the sapphire as rated upon the mineralogical scale is 9, next to the diamond, which is 10. That of emery is not necessarily indicated by the proportion of alumina, for a part of this may be in combination with the silica. It seems to vary with the water present, those samples containing the least water being the hardest.—In 1855 the annual production of emery was 2,000 tons of Naxos stone and 1,600 tons of Turkish. The whole business was concentrated in the hands of Mr. Abbott, who held the contract with the Greek government extending for 10 years, and had purchased the Turkish firman unlimited in time for the annual payment of \$55,000. An arrangement was entered into with the house of Messrs. John Taylor and sons of England to employ a capital of £120,000 in this business, and supply the emery either in the stone or powder to all parts of the world, with the guarantee of its being free from adulterations, such as had previously impaired its qualities and reduced its value. The principal consumption of the article is in polishing plate glass, and the increase of this business causes a constantly increasing demand for emery. The discovery of new localities is a matter of great importance, the few that are known in other parts of the world furnishing no supply capable of competing with that brought from the head of the Mediterranean. It is said to be found near Petschkau in Bohemia, near Ekaterinburg in the Ural, near Miask in the Ilmen mountains, and in Frederic valley, Australia.—Emery is prepared for use by crushing the stone under stamps, and sorting the powder into different sizes by appropriate sieves. For the most delicate uses of opticians, &c., it is separated in

a small way by a system of washing over called by chemists elutriation. After being ground, the powder is thrown into water, or water containing gum arabic, or it may be oil, and allowed to subside for a certain number of seconds or minutes. The process being systematically conducted, the powder is sorted into many sizes, and named according to the time the fluid was allowed to stand before the substance in suspension was collected, as emery of 10 seconds, of 30 seconds, 2 minutes, 30, 60, 80 minutes, &c. Emery is applied to paper, thin cloth, and slips of wood, by dusting the powder upon these articles, which are first coated with thin glue. They are then ready for sale or for use under the name of emery paper, cloth, or sticks. Mixed with paper pulp and fine glass and rolled into sheets, it forms the patent razor-strop paper; and by a variety of other methods it is prepared for its most convenient application to its numerous uses of grinding and polishing.

EMETICS, medicines used to produce vomiting. They may be divided into two classes, specific and irritant. The first class require for their operation that they be taken into the circulation, and they produce their specific effects whether they are absorbed from the stomach or injected directly into the blood. When taken internally their action does not commonly commence until after 20 or 30 minutes; then nausea, chilliness, and a feeling of weakness are produced, while the pulse is slow and soft; and as vomiting is induced, these give way to a flushed countenance, a warm skin, and a full pulse. Irritant emetics, as sulphate of zinc, copper, mustard, &c., on the other hand, produce vomiting by their direct effect upon the lining membrane of the stomach. Their action is immediate and unpreceded by any nausea or other precursory symptoms. They are used chiefly in cases of narcotic poisoning, and in cases of accumulation in the bronchial tubes, where from the feebleness of the patient it is desirable to shun the depression preceding the action of ordinary emetics, while full and prompt vomiting is required.

EMIGRATION, the act of leaving the country or place where one has previously resided, in order to reside elsewhere. In all European countries, Great Britain excepted, a formal relinquishment of the rights and duties of citizenship by the emigrant and the government respectively is required in order to render emigration legal. If no "certificate of expatriation" is obtained by the emigrant, his former government retains its claims on him, whether he becomes a naturalized citizen of another country or not. But even those emigrants who have been legally dismissed from the country of their birth are, in many European states, regarded as remaining under certain moral obligations toward their former government. They may be treated as traitors if they carry arms against their native state; it is also customary not to receive them as representatives of the foreign country to which they may emigrate. Thus the English government refused to receive

Count Rumford as the minister of Bavaria, he having been born a subject of the British crown. Formerly the principle that no subject could ever cease to owe allegiance to his government prevailed in Europe, and the statute books of England still contain laws forbidding the emigration of several classes of artisans; but they have become obsolete. The general rule in European countries is now to allow emigration, provided the emigrant has fulfilled all his obligations toward his native state; yet the question is still surrounded with many difficulties. The United States, by adopting foreigners as citizens without requiring a certificate of their dismissal from their original citizenship, have implicitly proclaimed the natural right of expatriation, that is to say, the right of every man to choose a government under which he intends to live. To this extent the right has not been acknowledged by any European state except Great Britain, and by the latter only practically, not legally. Cases have frequently arisen in which naturalized citizens of the United States, even those who came here as minors by the will of their parents, have been compelled, on travelling through the country of their birth, to do military duty, or have been punished for having failed to do so. The policy of the government of the United States in regard to such cases has been as unsettled as that of Great Britain. While, in 1853, Mr. Marcy, then secretary of state, in his famous Koszta letter, demonstrated the right and duty of the United States to protect even "inchoate citizens" against exactions arising from their former political relations, in 1858 the representative of the United States at Berlin was not sustained by his government in protesting against the forcible enrollment of naturalized American citizens in the Prussian army. It was held then, that when a foreigner became naturalized in the United States without having obtained permission to do so from his former government, he was entitled to the protection of the American government only within the territory of the United States, and, when returning to his native country under cover of an American passport, did so at his own risk. A distinct legal definition of the bearing of the act of naturalization upon the rights of the naturalized citizen in regard to his former government has never been attempted.—In some cases governments have been glad to lose a portion of their population, especially where the Malthusian theory of over-population prevails. Thus, British economists congratulated their country upon the great migration from Ireland to America about the middle of this century. Their theory was that by thus thinning out the population, the means of subsistence for those remaining must necessarily be increased. Possibly the peculiar political institutions of a country may authorize such a belief, but general experience tends to prove that an absolute over-population is out of the question even in the most densely settled European

countries. A relative over-population, caused by partial and insufficient development of natural resources, exists in the most thinly settled countries. Indeed, the lower the state of civilization the more frequent is a relative over-population. This is proved by the example of the American Indians, a few thousands of whom may starve for want of food on a territory large enough for a European kingdom. The limit of absolute over-population, that is, of the insufficiency of the natural resources to subsist a people, may have been reached in some provinces of China, but has not yet been pointed out by actual experience in Europe. It is a significant fact that the emigration from some European countries, Rhenish Prussia and Westphalia for instance, is in an inverse ratio to population; that is to say, the largest number emigrate from the most thinly settled agricultural districts, these having, relatively, a larger over-population than those in which agricultural and manufacturing pursuits are combined. The monarchical governments of Europe have from time to time endeavored to diminish emigration by oppressive laws, and by levying heavy taxes upon emigrants; but of late they have begun to perceive that such measures fail entirely to produce the desired result, and have therefore confined their efforts to the regulation and protection of emigration. Associations have been formed in many European states for this special purpose. In the United States there are likewise a number of similar associations devoting themselves to the assistance of immigrants. The United States government has passed laws for the regulation of emigrant ships (March 2, 1819; Feb. 22, 1847; May 17, 1848; March 8, 1849, &c.). The state of New York has established a board of commissioners which requires a tax of \$2 from every immigrant, and applies the proceeds of this taxation to the support of the needy and destitute among them. A depot for all immigrants arriving at New York, designed to protect them against fraud and violence, was opened in 1855. Similar measures have been adopted or proposed in the states of Wisconsin, Illinois, and Michigan, the latter of which in 1859 appointed agents for the purpose of drawing a portion of the emigration from Europe to the state of Michigan. In 1858 the German diet proposed certain rules for the restriction of emigration from Germany to America, but their adoption was retarded by the war beginning in April, 1859.—The history of emigration in the broadest meaning of the word is, in fact, the history of mankind. Of the earliest migrations by which the fundamental features of European history have been defined, no records remain, but numerous traces of them are found by the archæologist, ethnologist, and linguist. In the earliest stages of civilized life, when hunting was man's only means of subsistence, his wild roamings over large territories could scarcely be called emigration, since there were no settled habitations to leave or to go to. Emigration proper commenced when herdsmen congregated into

nomadic tribes. Of such corporate emigration patriarchal history records some examples, as those of Lot, Abraham, and Jacob. With the progress of agriculture and the growth of more definite political relations, trade, and commerce, began the emigration of single bodies of adventurers to distant countries. In this way Phœnicians, led by Cadmus, and Egyptians, led by Danaus and Cecrops, emigrated to Greece, the Heraclidæ from Greece to Asia Minor, the Tyrrhenians to Italy. Unlike these, the exodus of the Israelites from Egypt to Canaan was a corporate emigration of a people, on account of religious and political oppression, for which modern history furnishes parallels in the Mormon emigration to Utah and the emigration of the Boers in southern Africa. During the historical times of ancient Greece emigration generally assumed the character of colonization. Many flourishing and powerful colonies were thus sent forth along the shores of the Mediterranean and Black seas by Greece, the relative position of which in ancient history is similar in that respect to that of the Germanic (Anglo-Saxon) nations as contrasted to that of the Roman race. The colonies of ancient Rome for the most part were rather outposts of an army and combinations of fortune hunters than settlements of men intending to found permanent residences. The great migration of the Germanic nations having destroyed the Roman empire, the movements of European society were for centuries not unlike the whirlpool caused by the sinking of a large vessel. Nations and races were tossed hither and thither, and only a few out-of-the-way nooks and corners of Europe remained undisturbed. Charlemagne changed the direction of German emigration from the south to the east and north. While from that time the movements of German nations toward Italy assumed the character of mere military conquests, their emigration conquered nearly the whole country between the Elbe and Vistula rivers from the Slavic race. A counter current from Asia, which set in at various periods of the middle ages, consisting of Magyars and Tartars, was successfully resisted, and the tide was even turned upon Asia by the crusades; but at a later period another Asiatic race, the Osmanli (Turks), succeeded in displacing the most decayed of Christian nations in south-eastern Europe, while almost simultaneously still another Asiatic race (the Arabs) was expelled from the south-western peninsula (Spain), to which they had emigrated 8 centuries before.—Individual emigration, as distinguished from the movements of whole nations, commenced on a large scale after the discovery of America. During the 16th century the nations in which the Roman element predominated, Spain, Portugal, and France, sent forth a great number of emigrants, most of them mere adventurers who did not intend to stay longer than might be necessary to become rich. The first attempts by the English to organize emigration to America likewise originated in adventurous designs. In such attempts

800 men and £40,000 were lost from 1585 to 1590. In 1606 over 2,000 emigrants were sent from England to North America to seek for gold, but they perished miserably, and in 1609 but 60 of them remained. The Hakluyt company for the colonization of Virginia lost 2,000 men and £100,000. At last religious contests laid a firm foundation for the permanent settlement of the North American continent. The emigration of the Puritans and their successful establishment in New England served as an example to all those who in Europe were oppressed for the sake of their religion. Beside, the ground having been broken for the settlement of what are now the southern states of the Union, the fertility of their soil, their genial climate, and withal the still lingering hope of sudden enrichment by discoveries of precious metals, attracted large numbers of colonists. A strong tide of emigration from Germany set in toward Pennsylvania near the end of the 17th and during the 18th century; the Dutch colonized New York; the Swedes Delaware; Canada and Louisiana were settled by French adventurers. Still the current of emigration to America during the 170 years of the colonial history was slow and tedious when compared with that which commenced after the war of independence, and especially when the success of American institutions had been tested by the experience of one generation. Statistical tables of the number of alien immigrants were not kept until, in compliance with an act of congress of March 2, 1819, collectors of the customs began to report quarterly to the secretary of state the number, sex, age, &c., of passengers arriving by sea. There are, however, reasons to doubt the accuracy of the reports made within the first 10 or 15 years succeeding the passage of the act. Mr. F. Kapp attempts to prove from the records of several settlements, established between 1620 and 1830, that the number of immigrants who arrived during that time was larger than that given in the official reports. The immigration from 1784 to 1794 is stated by Mr. Samuel Blodget (1806) to have averaged 4,000 per annum. During 1794, 10,000 immigrants were estimated to have arrived in the United States, but this was an extraordinary number for the time. The yearly average of the immigration during 20 years, from 1790 to 1810, is assumed by Dr. Adam Seybert to have been 6,000. During the 10 years from 1806 to 1816 extensive emigration to the United States was precluded by the unfriendly relations at that time existing between Great Britain, France, and the United States; but soon after the restoration of peace it began again. During the year 1817 over 20,000 immigrants arrived. No trustworthy data exist on the immigration of the 21 months from Jan. 1, 1818, to Sept. 30, 1819. From the latter date to 1855, the number of alien passengers, and from 1856 to 1858 the total number of passengers (natives of the United States included) arriving by sea, are officially reported as follows:

The total number of alien immigrants who arrived in the United States from Sept. 30, 1819, to Dec. 31, 1855, is 4,912,624. Of the passengers coming by sea during the 8 years ending Dec. 1858, deducting therefrom those born in the United States, as also those who merely passed through the United States to the British provinces, &c., there remain about 550,000 souls. Estimating the number of immigrants who arrived from 1784 to 1819 at 150,000, we obtain a grand total of 4,912,624, or, in round numbers, 5,000,000 immigrants into the United States from 1784 to Jan. 1, 1859. Of this number about 2,600,000 came from Great Britain and Ireland; about 1,600,000 from Germany (including the whole of Prussia and Austria); 200,000 from France; 100,000 from British America; 50,000 from Sweden and Norway; 50,000 (?) from China; 40,000 from Switzerland; 36,000 from the West Indies; 12,000 from Holland; 16,000 from Mexico; 8,000 from Italy; 7,000 from Belgium; 5,500 from South America; 2,000 from Portugal; 1,800 from the Azores; 1,000 from Russia. It will be seen from the above table that the emigration to the United States increased in an unprecedented proportion from 1845 to 1854. This was owing in the first instance to the great famine in Ireland; in the second, to the revolutions of 1848, by which great numbers of those whose prospects had been blighted by political convul-

sions were induced to remove to the western continent. The year 1854 was also the turning point in the numerical proportion of the emigration from Ireland and Germany. In 1852 Ireland sent 160,000 emigrants to the United States, Germany but 145,918; in 1853 there arrived 164,000 emigrants from Ireland, and 141,946 from Germany; but in 1854 the Irish immigration fell to about 103,000, while the German increased to 215,009, and in 1855 there arrived 71,918 Germans (including Prussians and Austrians), and 50,000 Irishmen. In the port of New York there arrived in 1856, 56,117 German, and 43,996 Irish immigrants; in 1857, 86,859 German, and 57,106 Irish; in 1858, 31,874 German, and 25,097 Irish. From Jan. 1 to April 7, 1859, there arrived in the port of New York 7,193 immigrants, against 8,018 during the same period in 1858. The steady falling off of the immigration since 1854 is attributed to various causes, prominent among which are the strong reaction of the native American sentiment against the supposed deluge of the United States by aliens, and the financial crises of 1854-'7. It has been calculated that the number of 2,500,000 foreigners who had settled in the United States from 1784 to 1850 had during that period been swelled to 4,000,000 including their descendants. Assuming this to be correct, in 1860 the total of that portion of the population of the United States which is the product of immigration since 1784 would be near 7,000,000. But a close calculation is rendered exceedingly difficult by the fact that the proportion of age in an immigrant population is very different from that in a native one, there being always among the former a greater number of marriageable persons, but also a greater proportion nearer to the average period of human life. Of the total emigration from Europe, the largest portion is identical with the immigration into the United States. In a comparative statistical table, published by the French government in 1859, the total emigration during 10 years, from 1848 to 1858, from Great Britain and Ireland, is given at 2,750,000, from Germany at 1,200,000 (this number is given as 1,187,088 in the consular reports), but less than 200,000 from France. Hence it would appear that emigration is almost monopolized by the Germanic nations, among whom, in this respect, Sweden and Norway have since the middle of the 19th century begun to take a place. The total emigration from Europe in 1857 was, according to official statements, 352,378, viz.: 190,600 from Germany, 99,631 from Great Britain, 86,288 from Ireland, 13,802 from France, 8,151 from Sweden and Norway, 5,000 from Switzerland, 1,734 from Holland, 660 from Belgium, and 400 from Italy.—Next to the United States, the British colonies in America and Australia attract the greatest number of emigrants. The emigration from Great Britain and Ireland to British America from 1846 to 1857 averaged 40,000 per annum. The year of the Irish famine (1846) drew thither 109,680

emigrants. The emigration to Australia was formerly for the most part a forced one. From 1793 to 1838, about 74,000 convicts were transported thither. Since then the free emigration has gradually increased; in 1837, it was 2,664; 1838, 6,102; 1839, 7,852; 1840, 5,216; 1841, 12,188; 1842, 5,071; 1848, 23,904; 1849, 32,091; 1850, 16,037; 1851, 21,532; 1852, 87,424; 1853, 61,401; 1857, 61,248. The total emigration to Australia from 1849 to 1859 will scarcely fall short of 550,000. The aggregate of those who have emigrated from the United Kingdom either to British colonies or foreign countries from 1815 to 1853, is given by Mr. McCulloch at 3,793,529. Adding to this the emigration of subsequent years, as stated by other authorities (viz.: 339,524 in 1854, nearly 200,000 in 1855, 165,951 in 1856, 212,875 in 1857), we obtain a total of over 4,500,000 emigrants from the United Kingdom during a period of 43 years.—The emigration from Europe to other distant countries than those in which the Anglo-Saxon race predominates, has always been comparatively insignificant, in spite of all efforts of continental governments to push it in that direction. Algeria, in 1851, full 20 years after its conquest by the French, had an immigrant population of only 65,233. The emigration from France to Algeria amounted in 1856 to 8,564, and in 1857 only to 7,992.—Of the South American states, Brazil as early as 1819 endeavored to attract emigration from Germany and Switzerland, but the manner in which the emigrants were treated by the large property holders frustrated these efforts, although energetically repeated from time to time. Still, a few Swiss and German colonies have, after having passed through the severest ordeals, obtained a considerable degree of prosperity. Among these are New Freiburg, Petropolis, Leopoldina, and San Amarros, all in the neighborhood of the capital, and containing altogether some 12,000 inhabitants. Since 1851 the colonies of Donna Francisca, Blumenau on the Itajahazy, province of Santa Catarina, and Ybicaba, province of San Paulo, have been established. Emigration from Germany and Belgium to Costa Rica and Nicaragua (1850), and from Austria (Tyrol) to Peru (1857-'8), has generally resulted in failure. Emigration from Germany to Chili has been attempted with better success. The agricultural colonies established since 1850 in the province of Valdivia are in a highly prosperous condition, and may in no very remote time form the nucleus of a strong German population on the western slope of the South American continent. In 1859 a joint stock company for the establishment of German emigrant settlements in the republic of Ecuador was organized by German merchants in London under favorable auspices. An isolated case of successful colonization by people of the Roman race is the establishment of about 30,000 Frenchmen and Italians in the Argentine republic near the mouth of the river La Plata. Since 1857 strong efforts have been made in Germany to turn em-

igration in the same direction, and the hope has been expressed that by this means the La Plata country might be permanently acquired for the German race, but as yet scarcely any thing has been done to that effect.—In Europe, Russia was among the earliest to perceive the advantages of immigration. Peter the Great invited emigrants from all nations to settle in Russia. His successors followed the same policy by granting premiums and valuable privileges, such as exemption from taxation for a certain number of years, exemption from military duty, and free homesteads to colonists. Induced by these advantages, a large number of emigrants from the Palatinate settled in southern Russia in 1784. Immediately after the Napoleonic wars an extensive Germanic emigration to Russia (including Poland) took place. The total number of Germans who emigrated thither between the years 1816 and 1826 is estimated at 250,000. The agricultural colonies of Vielovish, in the government of Tchernigov, and Riebendorf, in that of Voronezh, a manufacturing colony near Pultowa, a Moravian settlement at Sarepta, and a number of German colonies in the Crimea, originated in this way. During the reign of Nicholas emigration to Russia ceased almost entirely, but since the accession of Alexander II. it has, to some degree, commenced anew in the northeastern provinces of Prussia, whence of late a considerable number of agriculturists have emigrated to Poland.—The Austrian government holds out inducements in order to draw a portion of the German emigration to Hungary, but so far with poor success. Immediately after the close of the Russo-Turkish war, the question was seriously discussed whether it would not be possible to regenerate the Orient by turning the tide of westward emigration to the lower Danubian countries and Asia Minor.—Of Asiatic nations, China furnishes the largest number of emigrants, hundreds of thousands of whom settle on the different islands of the Malay archipelago, the British, Dutch, Spanish, and Danish colonies, and also in Australia, the Sandwich Islands, and California. The annual average of Chinese emigration may reach some 200,000, but most of them do not remain permanently abroad. They return to their native country as soon as they have earned enough to live comfortably at home. We may here mention the peculiar system of emigration which within the last few years has been carried on under the auspices of the French government, viz.: the professedly voluntary emigration of negroes from the coast of Africa to French colonies. It is generally considered that this is simply the old slave trade in disguise.—That emigration which is uninterruptedly going on within the territory of the United States among the different states can scarcely be considered under the same head with the emigrations from nation to nation. According to the census of 1850, there lived in the different states and territories of the Union 4,176,225 white persons (viz.: 2,219,331 males, and 1,956,894 females)

born out of those states and territories respectively, but within the United States.

EMIR, an Arabic title, meaning prince or ruler, given in Turkey particularly to those thought to be of the line of Mohammed through his daughter Fatima, and to whom, in distinction from all others, belongs the right to wear a green turban. Properly, the emirs constitute with the ulemas only the first of the 4 castes of the Turks, but their number has so much increased that they are now estimated at $\frac{1}{3}$ part of the population of the Ottoman empire, and they are found in every class of people, even among the beggars. Emirs who perform servile duties do not degrade the green turban by continuing to wear it; and those who become generals, pashas, ministers, or even grand viziers, also dispense with it on public occasions, lest they may offend the sultan, who has not the honor of wearing it, not being of the race of Mohammed.

EMLYN, THOMAS, an English Unitarian divine, born in Stamford, May 27, 1668, died July 30, 1743. He was educated at Cambridge, and after travelling over England and Ireland settled in 1691 in Dublin, where he gained great reputation as a preacher. In 1697 he advanced doctrines upon the subject of the Trinity at variance with those of his congregation, declaring the Father preëminent over the Son and Spirit, and thus reviving Arianism. The opposition which was excited against him obliged him to leave Ireland, and he published in England a work declaring and aiming to justify his opinions. This book brought upon him a prosecution for blasphemy, and he was condemned to the penalty of a fine and a year's imprisonment. He did not pay the fine, but remained in prison 2 years, and after his release preached to a congregation of his friends in London. His character was amiable, and his life irreproachable. Beside his theological writings, which have been republished, he left memoirs of the life and sentiments of Dr. Samuel Clarke.

EMMANUEL, the same as IMMANUEL, a Hebrew word signifying "God with us." It is used by Isaiah in a prophecy which according to Matthew was accomplished in Jesus Christ, who is thus divinely recognized as the predicted Messiah, the true Immanuel, or "God with us."

EMMET. I. A N. W. co. of Iowa, bordering on Minn., intersected by the Des Moines river; area, about 450 sq. m. In its N. E. part are several small lakes. It has been formed since 1850, and was named in honor of Robert Emmet, the Irish patriot. It is not included in the state census of 1856. II. A new co. of Mich., called also Tonedagana, comprising the northern extremity of the lower peninsula, bordering on Lake Michigan; area, about 200 sq. m. It is not included in the census of 1850.

EMMET, ROBERT, an Irish revolutionist, born in Dublin in 1780, hanged in the same city, Sept. 20, 1803. He gained high honors at Trinity college, from which he was ultimately

expelled for avowing himself a republican. He joined the association of united Irishmen, whose object was to separate Ireland from Great Britain and to establish an independent republic, and he was implicated in the rebellion of 1798. After the failure of this attempt he escaped to France, returned secretly to Dublin in 1802, reorganized the malcontents, established various depots of powder and firearms in different parts of the city, and fixed upon July 23, 1803, as the time to seize the castle and arsenals of Dublin. On the evening of that day he directed the distribution of pikes among the assembled conspirators, to whom he delivered an animated harangue. The insurgent band, marching with cheers into the principal street, and being swelled into an immense and furious mob, assassinated Chief Justice Kilwarden, who was passing by in his carriage, but hesitated to follow their enthusiastic leader to the castle, and dispersed at the first volley from a small party of soldiers. Emmet, in disgust at the outrages and pusillanimity of the insurgents, abandoned them and escaped to the Wicklow mountains. After the failure of the first blow he checked the other movements which had been projected, husbanding his resources in the hope of soon renewing the revolt. He might have evaded the pursuit of the government, but a tender attachment which subsisted between him and Miss Curran, the daughter of the celebrated barrister, induced him to return to Dublin to bid her farewell before leaving the country. He was tracked, apprehended, tried, and convicted of high treason. He defended his own cause, delivering an address to the judge and jury of remarkable eloquence and pathos, met his fate with courage, and won general admiration for the purity and loftiness of his motives. His fate and that of Miss Curran are the subjects of two of the finest of Moore's Irish melodies.—THOMAS ADDIS, brother of the preceding, a politician and lawyer, born in Cork in 1765, died in New York, Nov. 14, 1827. He was graduated at Trinity college, Dublin, studied medicine at the university of Edinburgh, visited the most celebrated schools of the continent, then selected the legal profession, studied 2 years at the temple in London, and was admitted to the bar of Dublin in 1791. He soon became a leader of the association of united Irishmen, and was one of a general committee to superintend all similar associations, having rebellion for their ultimate object. Disclosures being made to the government, he was arrested with many of his associates in 1798, did not deny his purposes, and was finally conveyed a prisoner to Fort George in Scotland, where he was confined 2½ years. After the treaty of Amiens he was liberated and permitted to withdraw to France, the severest penalties being pronounced against him if he should return to Ireland. His wife obtained permission to join him on condition that she should never again set foot on British soil. From Brussels, where he passed the winter of 1802-'3, he saw his brother Robert

embark in the enterprise which led him to the scaffold. He came to America in 1804, rose to eminence in his profession in New York, and was attorney-general of that state in 1812. While in prison in Scotland he wrote sketches of Irish history, illustrative especially of the political events in which he had taken part, which were printed in New York in 1807.—JOHN PARSON, son of the preceding, an American physician, born in Dublin, April 8, 1797, died in New York, Aug. 13, 1842. He came with his father and other Irish exiles to the United States, was educated for 3 years in the military school at West Point, resided for one year in Italy, and studied medicine after his return. His delicate health obliging him to seek a milder climate, he removed to Charleston in 1822, and began the practice of his profession. He was in 1824 elected professor of chemistry and natural history in the university of Virginia, and during several years was a contributor to Silliman's "Journal."

EMMITSBURG, a post village of Frederick co., Md., in the midst of a fertile and thickly populated region; pop. in 1850, 812. It contains several churches, an academy, an asylum for female orphans, an institute for girls, under the care of the sisters of charity, and Mount St. Mary's college and theological seminary, a flourishing institution supported by Roman Catholics, which in 1858 had 24 professors, 126 pupils, and a library of 4,000 vols.

EMMONS, NATHANIEL, D.D., an American theologian, born in East Haddam, Conn., April 20, 1745, died in Franklin, Mass., Sept. 23, 1840. He was graduated at Yale college in 1767, was licensed to preach in 1769, and ordained pastor of the church in Franklin, where he spent his days, in April, 1778. He continued in the pastorate till 1827, a period of 54 years. He claimed to be a genuine Calvinist, though differing from the theological views of Calvin in several important respects. Of some of his peculiar speculations, one is, that there is no such thing as holiness or sinfulness, except in the exercise of the voluntary affections, so that there is no depravity except in voluntary disobedience; and another, that God is the efficient, producing cause of every act of the human mind, thus making the will of God the source of all sinfulness as well as holiness, while every moral act, he would claim, is at the same time perfectly free and voluntary on the part of man. Dr. Emmons was one of the founders and first president of the Massachusetts missionary society, and one of the editors of the "Massachusetts Missionary Magazine." He guided the studies of some 87 theological students. His writings published in his lifetime were numerous, and his complete works, in 6 vols., edited with a memoir by the Rev. Jacob Ide, D.D., were published in Boston in 1842.

EMORY, JOHN, D.D., bishop of the Methodist Episcopal church, born at Spaniard's Neck, Queen Anne's co., Md., April 11, 1789, died Dec. 16, 1835. He was graduated at Washing-

ton college, Md., studied law, and was admitted to the bar in 1808; but after practising a short time with success, he resolved to devote himself to the ministry, and entered the Philadelphia M. E. conference in the spring of 1810. From 1813 to 1820 he filled some of the most important stations in the church, including Philadelphia, Baltimore, Washington, and other cities, and was sent as a delegate to every general conference, except one, from the time he became eligible until the close of his life. At the conference of 1820 he was chosen to represent the American Methodist church in the British conference, and in 1824 was elected junior agent of the Methodist book concern, and principal agent at the ensuing conference, in 1828. His labors in this department of the church were of great service, and, having placed the institution upon a permanent basis, he was elected bishop by the general conference of 1832. His presidency in all the conferences during the short period of his episcopate was entirely satisfactory. He not only attended the sessions of the various conferences falling in his division of the plan of episcopal visitations, but he entered largely into the subject of education, assisting in the organization of the New York university, as well as the Wesleyan university and Dickinson college. He also directed his attention to the improvement of the ministry, and prepared a course of study which has proved of great service in elevating the standard of ministerial education in the Methodist Episcopal church. He was killed by being thrown from his carriage. Bishop Emory's writings were mainly controversial, among them being "Defence of our Fathers" (8vo., New York, 1827), and "The Episcopal Controversy Reviewed" (8vo., 1838). These, with a life by his son, reappeared in 1 vol. 8vo. in 1841.—ROBERT, son of the preceding, an American clergyman, born in Philadelphia, July 29, 1814, died in Baltimore, May 18, 1848. He was graduated at Columbia college in 1831, and shortly afterward commenced the study of law. In 1834, upon the reorganization of Dickinson college, he was called to the chair of ancient languages, but resigned his professorship in 1839, in order to embrace the ministry, and entered the Baltimore annual conference of the Methodist Episcopal church. He was, however, in 1842, by the unanimous request of the faculty of the college, recalled, as president *pro tem.*, during the absence in Europe of President Durbin, upon whose resignation Dr. Emory was chosen his successor. This office he held until the close of his life. Beside a life of his father, he left a "History of the Discipline of the Methodist Episcopal Church" (8vo., New York, 1843, revised and brought down to 1856 by the Rev. W. P. Strickland, D.D.), and an unfinished "Analysis of Butler's Analogy," which was completed by the Rev. George R. Crooks, D.D. (12mo., 1856), and has been introduced as a text-book into many institutions of learning.

EMPEDOCLES, a Greek philosopher, born at Agrigentum, in Sicily, flourished about the

middle of the 5th century B. C. The son of a rich family, he was instructed by the Pythagoreans, and was acquainted, it is said, with Parmenides and Anaxagoras. Like his father, Meton, the leader of the popular party at Agrigentum, he saved the republic from a dangerous conspiracy, and refused the supreme power when it was offered him. A priest and a poet, a physician and a philosopher, his contemporaries esteemed him as a god; Plato and Aristotle admired him, and Lucretius sang his praises. He saved the life of a woman plunged into a lethargy, from which the art of other physicians was powerless to revive her. He blocked up a mountain gorge through which pestilential winds were driving upon Agrigentum, and at another time stopped the raging of the plague by turning two rivers through a morass. His vanity equalled his ability. He appeared in public only in the midst of a retinue of attendants, with a crown upon his head, sandals of brass on his feet, his hair floating over his shoulders, and a branch of laurel in his hand. He proclaimed his divinity himself, and it was recognized throughout Sicily. In acting his part and spreading his ideas among men, it was his aim not less to affect the imagination than the reason. In his old age he left Sicily, not, as has been said, to converse with the priests of Egypt and the magi of the East, but to teach philosophy in Greece. He visited Thurium and Athens, sojourned in the Peloponnesus, and read a poem at the Olympic games which gained the applause of all Greece. His last days were passed in obscurity in the Peloponnesus. Some imagined that he was translated to heaven and received among the gods; others that he was drowned in the sea, that he fell from his chariot, that he was strangled by his own hand, or that he plunged into the crater of Etna, in order by hiding his body to certify his divinity, but that the volcano subsequently belched forth one of his sandals. Of all these fables the last, which has been the most widely received, is the most preposterous. The works of Empedocles were all in verse, embracing tragedies, epigrams, hymns, and an epic. The most important of them were two didactic poems, one on "Nature," treating of cosmology, physiology, and psychology all together; the other on "Purifications," treating of worship and magic, and containing his religious precepts. Fragments only of these remain, but those of the treatise on nature are sufficient to give an idea of the plan of the work. It consists of 3 books: in the first, after stating the conditions of human knowledge, he treats of the universe in general, of the forces which produce it, and the elements which compose it; in the second, of natural objects, of plants and animals; and in the third, of the gods and divine things, and of the soul and its destiny. Even in philosophy, Empedocles remains a poet. A Homeric spirit, as Aristotle calls him, he personifies and deifies every thing, and robes himself in symbols and mystery. The doctrine of Empedocles is developed in the "Sophist," the

"Meno," and the "Phædo" of Plato, and in the "Soul" and the "Metaphysics" of Aristotle. The best edition of his remains is that by Karsten (Amsterdam, 1838), which is furnished with admirable dissertations.

EMPEROR (Lat. *imperator*, commander), a title bestowed in the Roman republic on chief commanders of great armies, on consuls elect before entering upon their office, and often used by victorious troops to hail on the battle field a successful general. In later times it designated the highest authority in the state. Cæsar, returning from his last campaign, after the victory of Munda (45 B. C.), and Octavianus Augustus, after the battle of Actium (31 B. C.), assumed this now regal title in preference to the odious *rex*, and Rome became an empire. Augustus and his successors took in addition the name of Cæsar, and both the title and the name (*Kaiser*) were afterward adopted by monarchs of other states. When the rule of the Roman empire was divided, the name Cæsar designated the adopted assistant of the emperor, who was himself honored by the title of Augustus. These titles disappeared in the West with the fall of Rome (476), but were saved in the eastern or Byzantine empire for nearly 10 centuries, not by the virtues or warlike spirit of those who bore them, but by the happy location of the capital, by the Greek fire, and Grecian bribery. During the crusades we find also a Nicæan and a Trapezuntine empire in the East. But all these eastern states were swept away and replaced by the power of the Turks, whose sultans, however, never officially adopted the title of the vanquished Christian monarchs. This had been restored in the meanwhile in the West by Charlemagne, who received the imperial crown from the hands of Leo III. at Rome on Christmas day, 800, and was hailed by the people with shouts of "Life and victory to Carolus Augustus, the God-sent, pious, and great emperor of Rome, the bringer of peace." When the empire of this great Frankish monarch was divided by his grandsons, the title of emperor of Rome was given to the eldest of them, the king of Italy, and his descendants bore it until it was taken (962) by the mightier king of Germany, Otho I. And now began a long series of expeditions to Italy, undertaken by the German monarchs, in order to be crowned in Milan with the iron crown of Lombardy, and in Rome by the pope with that of the Roman empire; a series of struggles between the emperors, claiming the sovereignty of the Roman world according to their title, and the popes, claiming the same as successors of St. Peter; between the worldly and spiritual heads of the Christian nations, the Othos, the Henrys, and the Frederics, and the Gregorys, the Alexanders, and the Innocents. German bravery and Italian diplomacy, the sword and the bull, were by turns victorious and vanquished; emperors were humiliated, popes were ignominiously stripped of their dignity; Germany was distracted and Italy desolated. But new states had grown, new ideas sprung

up, new aspirations arisen; the reformation struck boldly at the pope, and indirectly at the empire. It was at that time that the German kings, who usually had been elected as such, exclusively from Frankish or German houses, in earlier times by all, but later only by the greatest princes of Germany, who were hence called electors, gave up their Roman imperial pretensions, and were crowned in Germany as emperors of that country. At their coronation, celebrated in Aix la Chapelle, Augsburg, Ratisbon, or Frankfort, with great display both of splendor and servility, the emperors were obliged to sign an instrument, called capitulation, containing the conditions under which they were raised to their dignity. They lived in *palatia* set apart for their use (*Pfalzen*), in later times in their hereditary dominions. The wars of the reformation broke the ancient forms and institutions; the imperial dignity became almost hereditary in the house of Austria; the other German states were made nearly independent; Prussia became a kingdom under Frederic I.; the unity of Germany was virtually destroyed. The wars that followed the French revolution wrought still greater changes, and when Napoleon had assumed the imperial dignity (1804), and founded the Rhenish confederacy, Francis II. in 1806 changed his title into that of emperor of Austria (as such Francis I.), and what was once the Roman, now the German, empire expired. Its restoration was during the revolutionary period of 1848-'9 the favorite idea of a party in the Frankfort parliament. The refusal of the king of Prussia to accept the imperial crown made the scheme a failure. In the meanwhile several other monarchies of Europe had taken the imperial title. Russia assumed it under Peter the Great (1721), and the assumption was in time acknowledged by all the states of Europe. The empire of the French, founded by Napoleon on the ruins of the republic, perished at Waterloo (1815), to be revived after two revolutions by the nephew of its founder (1852). On the American continent several empires have been established, but most of them destroyed by revolutions. That of Mexico under Iturbide (1822) was ephemeral; that of Brazil is governed constitutionally; that of Hayti, which was nominally constitutional, was overthrown in Jan. 1859, and replaced by a republic. The Asiatic states of China, Japan, and Anam, the African Fez and Morocco, are also often called empires.

EMPHYSEMA, a diseased condition of man and animals, in which gases are developed in or have been introduced into any part of the body; restricted, however, generally to the dilatation of the cells of areolar tissue or of the lungs by atmospheric air. Gaseous collections in serous cavities, or in canals lined with mucous membrane, have received other special names. Three kinds are usually described, which may be called surgical or traumatic, spontaneous, and pulmonary emphysema. Traumatic emphysema, though always subcutaneous in the com-

mencement, is not always accompanied by wound of the skin; it may occur after severe contusions of the chest, or after fracture of the ribs, the air cells of the lungs being ruptured, and in the latter case punctured by the broken bone, with or without external communication. In any of these conditions, if the wound of the lung be small, and especially if it be not in direct connection with an opening in the skin, the respired air, not being able to pass out freely, becomes infiltrated in the areolar or cellular tissue, forming a soft and crepitating swelling, which may extend over a great part of the body; during inspiration the air escapes into the cavity of the chest through the wound in the lung, and during expiration, being compressed between the lung and the thoracic walls, it is forced into the subcutaneous cells, the amount tending to increase at each performance of the respiratory act. Emphysema may arise from any portion of the air passages, and frequently is seen accompanying wounds of the larynx and trachea; if the external wound be extensive, and the opening in the lung or trachea small, this complication is not likely to occur. The ordinary symptoms are painful constriction of the chest at the injured part, and difficulty of breathing, which may become almost insupportable, and even produce death by suffocation. The swelling of emphysema may be distinguished from effusions of fluids under the skin by its crepitation and elasticity, by its not pitting on pressure of the finger, and by the absence of redness, pain, and weight. After distending the cellular tissue under the skin, the air may penetrate between the muscles, along mucous canals, vessels, and nerves, to the inmost recesses of the organism. The treatment consists in letting out the confined air by minute punctures with a lancet, by preventing its reaccumulation by proper bandages, and in cases of extreme oppression by paracentesis or incision of the thoracic walls; the cure may be hastened by antiphlogistic measures, and by stimulating applications and frictions. In Europe it is not uncommon for persons desirous of securing immunity from military service, and for purposes of mendicancy and deception, to artificially inflate with air various parts of the surface of the body, and to pretend that their condition is the result of chronic or congenital diseases; the treatment in these cases consists in scarifications, bandages, and tonic frictions. After exposure to great cold, in certain cases of internal poisoning and of poisonous bites, after copious bleedings and various severe accidents, and in debilitated conditions accompanied by gangrene, there occasionally arises an emphysematous complication, which is treated in the same manner as the preceding variety.—Pulmonary emphysema may be either vascular or interlobular. In the first the vesicles are enlarged, ruptured, and united together, and the lungs, when the chest is opened, may be so distended, more especially the upper lobes, as to protrude from its cavity; when only one side is affected, it press-

es upon and displaces the heart and the other lung; such diseased portions are strongly crepitant, part with their contained air with difficulty, and float very lightly on water. In interlobular emphysema the distended vesicles assume an irregular form, sometimes of considerable size, and are situated just under the pleura; they may be made by pressure to move under the serous covering as far as the next lobular division of the organ; sometimes the enlarged vesicles are not in the subserous tissue, but in the tissue separating the lobules, between which they may descend to a considerable depth. These varieties are usually combined, their symptoms are the same, and the latter is generally considered the consequence of the former, the distention and rupture of the vesicles proceeding to a greater extent. Laennec and Piorry maintained that pulmonary catarrh was one of the principal causes of the dilatation of the vesicles, which, unable to free themselves from the viscid mucus without great effort, of necessity became enlarged; Louis seems to consider that there is some power of active dilatation brought into play, though he gives no satisfactory definition of the agency. Admitting the connection between emphysema and obstructed bronchi, with the first-named authors, there is no necessity for making the former a direct consequence of the latter; measured by a pressure gauge, the forced expiratory act has been found $\frac{1}{2}$ more powerful than the act of forced inspiration; as Dr. W. T. Gairdner has well observed (in his work on bronchitis), whenever viscid obstructions are to be removed from the air passages, the air is gradually expelled from the affected part of the lung by expiration, and they become collapsed in proportion to the obstruction. Emphysema is the direct opposite to bronchial collapse, and the indirect consequence of it; because, whenever a part of the lung is obstructed or collapsed from bronchitis or any other cause, the air during inspiration must rush with greater force and volume into the portions still freely open. Bronchitic accumulation and collapse are most common at the posterior and lower part of the lungs, and emphysema on the free anterior borders; the emphysematous portions are easily inflated from the bronchi, while the collapsed parts are not. Emphysema is, therefore, essentially a mechanical lesion from distention of the air cells, in proportion to which the flow of blood through the ultimate capillaries of the lungs is arrested, causing absorption of their walls, and tension and obliteration of their vessels. In the case of Mr. E. A. Groux, with congenital fissure of the sternum, in the course of prolonged forced expiration, the chest and abdomen become smaller, the veins at the root of the neck swollen, the upper intercostal spaces convex, and the fissure assumes its greatest width; and above the pulsatile cardiac tumor is a protruding mass which percussion shows to be the anterior portion of the upper lobe of the right lung. This can throw little light on the ordinary

causes of emphysema, though the cells are doubtless dilated, because the protrusion is evidently due, not so much to the obstructed passage of air or blood, as to active muscular effort, and to the raising of the whole thoracic contents by the diaphragm and abdominal muscles in a cavity whose bony wall is deficient in front, where of course the free portion of the lung would protrude. Emphysema has been traced to compression of the bronchi by tumors; to the great respiratory efforts required in playing on certain wind instruments, showing the connection between this disease and forced expiration, and as partly exemplified in the above case of Mr. Groux; the disposition to this disease has also been considered hereditary, and doubtless many cases of so called hereditary phthisic or asthma are due to the vesicular dilatation consequent on spasmodic bronchial contractions. It is found in both sexes, at all ages, and in all constitutions; once developed, it remains during life, sometimes stationary, but generally increasing, with irregular intervals of ease; the dyspnoea is sometimes such that the patient is obliged to sit up in order to breathe; slight causes, as a catarrh, exposure to irritating gases or dust, or vivid emotions, are sufficient to bring on an attack. Examination of the chest will show an enlargement of the affected side at the upper region of the ribs and intercostal spaces. On percussion the chest is very sonorous, and the respiratory sounds feeble, with râles sonorous, dry, or humid, according to the accompanying catarrhal condition, and the presence or absence of cough. It is a very common disease, generally chronic in its nature, but sometimes acute and speedily fatal. It may be known by the occurrence of dyspnoea, without palpitations, disease of the heart, œdema, or fever, and often without any signs of catarrh. The principles of treatment are to guard against pulmonary congestion by proper depletives, to diminish the frequency of respiration by opium and other sedatives, to strengthen the weakened system by tonics, to relieve the obstructed bronchi by emetics and expectorants, and to avoid all the exciting causes of catarrh and bronchitis, the most frequent originators and aggravators of the disease.

EMPSON, WILLIAM, a British author and critic, born in 1790, died at Haileybury, near Hertford, Dec. 10, 1852. He was educated at Winchester and at Trinity college, Cambridge, and upon the retirement of Sir James Mackintosh became professor of law at the East India company's college at Haileybury, a position which he occupied until his death. Subsequent to 1830 he was the editor of the "Edinburgh Review," to which his contributions were numerous. That which attracted most attention was on Stanley's "Life of Arnold." He married the only child of Francis Jeffrey, who addressed to him some of his most interesting letters.

EMPYREUM, or EMPYREAN (Gr. *εὔρη*, in, and *πῦρ*, fire), a name given by the fathers of the church and the ancient theologians to the highest point of the heavens, where was the habi-

tation of the Deity, according to the description of St. Paul, *Lucem Deus habitat inaccessibilem*, and where the saints enjoyed the beatific vision.

EMS, or BAD-EMS, a German watering place in the duchy of Nassau, on the Lahn, 15 m. N. from Wiesbaden, to which and to Baden-Baden it is inferior in extent and splendor; pop. about 4,000. It is shut in by mountains, surrounded by picturesque scenery, and has a terrace by the river side serving for a promenade. The *Kurhaus*, a large chateau, formerly a ducal residence, is let in apartments to visitors, beside which the place has a number of lodging houses, and a new *Kursaal* built by the grand duke at the side of the Lahn, containing a *café*, a ball room, and gambling saloons. The number of visitors is about 4,000 or 5,000 annually, comprising many English and Russians. The revenue from the gaming tables forms an important item in the receipts of the duchy of Nassau, but the duke's subjects are not permitted to play. The springs, which have been famous since the 14th century, and are supposed to have been known to the Romans, are used for both bathing and drinking. The waters are more or less impregnated with carbonic acid, have a temperature of from 93° to 135° F., and are esteemed for their efficacy in nervous, liver, and dyspeptic complaints, and also in diseases of the chest and eyes.

EMS (anc. *Amisia* or *Amisius*), a river of N. W. Germany, rising in Lippe-Detmold, passing through Hanover, and flowing into the Dollart. It is an important channel of communication, is navigable about 13 m. by vessels of 200 tons, and is 234 m. long.

EMSER, HIERONYMUS, one of the most active opponents of Luther among the Roman Catholic theologians of Germany, born in Ulm in 1472, died Nov. 8, 1527. In 1502 he became professor at the university of Erfurt, where Luther is said by him to have been among his pupils. In 1504 he established himself at Leipzig, where he also lectured at the university, and in the year following Duke George of Saxony made him his secretary. With Luther and the theologians of Wittenberg generally he was on good terms until the disputation of Leipzig in 1519, from which time he made, in union with Dr. Eck, incessant endeavors to oppose the increasing influence of Luther and the progress of Protestantism. The German translation of the Bible by Luther was attacked by him as erroneous, whereupon it was forbidden in Saxony by Duke George. Emser then himself published a translation of the New Testament into German, made from the Vulgate (Dresden, 1527). He also wrote *Vita S. Bennonis*, as he ascribed to St. Benno his recovery from a severe sickness.

EMU (*dromaius Novæ Hollandiæ*, Latham), a bird closely allied to the cassowary, a native of New Holland and the adjacent islands. The emu differs from the cassowary in its broader bill, in its head covered with feathers above, and in its smaller and more obtuse claws; as in the latter, the cheeks and sides of the neck

are naked, the legs long and robust and protected by strong scales, and the wings and tail not apparent; the middle toe is the longest, the inner the shortest. This bird was named emu by the English colonists, who confounded it with the cassowary or emu of the Moluccas; to distinguish them, ornithologists call the present bird New Holland emu. There is only one species of the genus, living in the *eucalyptus* and *casuarina* forests in the Australian islands. Its length is about 7 feet; its plumage is thick, and of a brownish color. The feathers are remarkable from their two central stems being united at the base, bearing simple barbs, and sometimes very short barbules. The form is thick and heavy, the back arched, the denuded neck of a violet color, and the feathers on the head are few, simple, and hair-like. The emu presents the closest analogy to the ostrich in its anatomical structure; a wide membranous sac is formed below the crop by a dilatation of the œsophagus, which ends in a slightly developed gizzard; the intestinal canal is about 16 feet long; the windpipe is very long, and at its 52d ring opens into an immense muscular sac, whose use is not well ascertained; according to Wagner, the bones of the wrist are wanting in this bird. The natives of New South Wales call the emu *parembang*. It is a timid bird, running with great rapidity, and very rarely taken; it was once common in the neighborhood of Sydney, but civilization has now driven it beyond the Blue mountains. It prefers open shrubby places and sandy plains. When pursued it takes readily to the water, and swims with its body mostly submerged. It feeds on fruits, berries, roots, and various herbs. The female lays 6 or 7 eggs, in a slight hollow scratched in the earth; the male hatches the eggs, and takes care of the brood until they can provide for themselves; the young are of a grayish color, with 4 bands of bright red. The flesh is eaten by the natives, and is said to have the taste of beef.

ENALIOSAURIANS (Gr. *ενάλιος*, marine, and *σαυρος*, a lizard), an order of fossil marine reptiles, found in the liassic, triassic, and cretaceous epochs. They present the strangest forms, uniting in their structure characters which appear at first sight incompatible. They have the vertebræ of fishes, the teeth of crocodilians, the body of lizards, the paddles of cetaceans or marine turtles, and some have a long snake-like neck. Many of these aquatic saurians attained a large size, and from their voracity must have been the terror of the waters of the secondary epoch, after the disappearance of the great sauroid fishes of the carboniferous period. Pictet considers them as coming nearest to the saurians, though so different from any existing types as to require the establishment of a new order, whose principal characters are biconcave vertebræ, wider than long, with laminæ feebly united to the bodies; conical teeth, without cavity at their base, implanted in short deep-seated alveoli; and 4 short, flattened limbs, whose fingers are formed

by discoidal bones disposed like those of cetaceans. They have been divided into 2 groups whose characters correspond also to their geological position. The ichthyosaurians (including the *ichthyosaurus* and *plesiosaurus*) have well developed crania, with small fossæ and cavities; these have been found in the jurassic and cretaceous strata. The other group, the simosaurians (including *nothosaurus*, *simosaurus*, &c.), have the cranium with very large temporal, frontal, and orbital and nasal cavities; they are found only in the triassic strata. The first two groups are the best known, and the most common in the strata of England and Germany; the *ichthyosaurus* must have attained a length of nearly 20 feet, and the *plesiosaurus* of more than 12 feet; both presented forms most unlike those of any existing animals, though admirably adapted to the circumstances in which they lived. (§ ICHTHYOSAURUS, and PLESIOSAURUS.)

ENAMBUO, PIERRE VANDROSQUE DIEPPE, a French navigator, born in Dieppe, died in St. Christopher, W. I., Dec. 1686. Being of adventurous spirit, he sailed from Dieppe in 1625 in a brigantine of 8 guns, for the Antilles. He landed in the island of St. Christopher on the same day with a party of English colonists with whom he divided the island, and, at his death, held the French half of the colony with extraordinary tenacity. In 1685 he took possession of Martinique in the name of the king of France, and founded the town of St. Pierre.

ENAMELLING, the art of applying a coating of vitreous substances called enamels to the surface of glass or of metal, and baking this by a fusing heat. In its homeliest application it is a sort of glazing, and as applied by modern methods to ornament and protect the surface of cast or wrought iron, it may be considered simply a process of JAPANNING, which see. From the facility with which colors might be introduced in the vitreous compounds or applied to them and become fixed by a second baking, this art was in early times exceedingly popular, and in the middle ages it attained a higher reputation even than it now holds, as one of the fine arts. The ancient Persians and Arabians appear to have practised it upon earthenware and porcelain; and the mode of coloring this ware at the present day is properly a process of enamelling, as will be seen in the description to be given of this manufacture. Articles of pottery enamelled in colors are found among the ruins of ancient Thebes, and in many of the cities of Egypt are buildings constructed of enamelled brick taken from the ruins of older cities. Wilkinson states that "it has been questioned if the Egyptians understood the art of enamelling upon gold or silver, but we might infer it from an expression of Pliny, who says: 'The Egyptians paint their silver vases, representing Anubis upon them, the silver being painted and not engraved;' and M. Dubois had in his possession a specimen of Egyptian enamel." From the Egyptians the art is supposed to have passed to

the Greeks, and afterward to the Romans. Brongniart, however, in his *Traité des arts céramiques*, traces its introduction into Italy from the Balearic isles by the Spaniards, who derived the art from the Arabs. The Romans introduced it into Great Britain, as appears from various enamelled trinkets that have been dug up there with other vestiges of the Roman conquerors. That the Saxons practised the art appears from an enamelled jewel found in Somersetshire, and preserved at Oxford, which bears an inscription stating that it was made by direction of the great Alfred. The gold cup given by King John to the corporation of Lynn in Norfolk shows, by the colored enamelled dresses of the figures with which it is embellished, that the Normans also practised the art. Among the Gauls enamelling upon metallic surfaces is understood to have been in use in the 8d century. As practised upon earthenware in the style called by the French *faïence commune ou émaillée*, and by the Italians *majolica* ware, it was carried to great perfection in the 16th century at Castel Durante and at Florence by the brothers Fontana d' Urbino. Other Italian cities adopted the favorite art, and Faenza became famous for the works of Guido Selvaggio. The articles produced in this style were rather objects of luxury than of use. Some were utensils for the tables of princes, adorned with the most delicate sculptures and splendid paintings. There were also vases of numerous forms, small flasks covered with tendrils, figures of saints, birds of brilliant plumage, painted tiles, &c., all formed merely of baked clay covered with an opaque enamel composed of sand, lead, and tin, upon which the designs, in some instances those of Raphael, were painted in enamel colors and baked in. This high style hardly outlived the artists who perfected it; and from 1560 it gradually deteriorated. Bernard de Palissy, by practice of 25 years directed to the production of a cup like one of great beauty shown to him, sought to introduce the art in France, and his works became very famous, but his method died with him. His productions were interesting as true copies of natural objects, in relief, and colored with exact faithfulness. Some of these objects were fossil shells from the Paris basin. Of late years the art has been revived in France, chiefly through the skill of M. Brongniart; and in Berlin also beautiful work of the kind has been executed by M. Feilner.—Painting in enamel, as practised upon plates of gold and copper, can hardly be regarded as applied to works of high art until the 17th century. Jean Toutin, a goldsmith at Châteaudun, appears about the year 1680 to have first made enamels of fine opaque colors, and applied them to portraits and historical subjects. Other artists profited by his instructions, and several miniature painters attained great distinction in this branch. The art afterward fell into disuse, and was only applied to ornamenting watch cases and rings. In the early part of the present century it reappeared

in some fine portraits by Augustin, and various French and English artists have since executed many fine portraits in this style, distinguished for the brilliancy of their colors, and the more valuable for their permanency. A piece of 5 inches in its longest dimensions was considered the largest that could with safety be undertaken; for with the increase of size the liability of injury to the enamel by cracking, and to the plate by swelling and blistering in the several processes of baking, rapidly increased; but by backing the metallic plate with one of porcelain, the work is now executed in pieces of much larger dimensions, even 18 inches by nearly as great a breadth. The process is usually conducted as follows. The plate is coated on both sides with a ground of white enamel, and on this the design is lightly sketched with a pencil, using red vitriol mixed with oil of spike. The colors, finely ground and mixed with oil of spike, are then laid on as in miniature painting. By gentle heat the oil is evaporated, and in an enameller's fire the plate is next made red-hot to incorporate the colors with the enamel. The painting may then be retouched, and the colors, again be burned in, and this may be repeated several times if necessary. But the greatest accuracy in the first drawing and coloring is essential for a perfect picture. In this department may be consulted the work of Count de Laborda, *Notice des émaux exposés dans les galères du Louvre*.—In the ordinary processes of enamelling, the enamels used for the ground are opaque, and must bear a higher degree of heat without fusing than the colored enamels, which are afterward melted into them. They are made after a great variety of recipes, according to the uses to which they are to be applied. All those designed for metallic surfaces have a transparent base, which is rendered opaque by the substitution of combined oxide of lead and oxide of tin, in the place of the oxide of lead used as one of its ingredients. Five different mixtures of the two oxides are in use, the proportions varying from $3\frac{1}{2}$ parts of lead and 1 of tin to 7 parts of lead and 1 of tin. The two metals, in the desired proportion, are melted together, and the combined oxide is removed as fast as it appears upon the surface. When the oxidation is as thoroughly effected as practicable, the product is well washed to remove any particles of metal that may have escaped oxidation, as these would greatly impair the quality of the enamel; for the same reason it is essential that the metals themselves should be absolutely pure and free from the usual alloys found with them. One or other of the mixtures of oxides obtained by the method described is next melted with proper quantities of silica (pounded quartz), saltpetre, and a little borax; the last gives greater fusibility as its proportion is increased, and no more is used when the enamel is to be applied upon copper or silver than upon gold. The plates are sometimes chemically acted on by the enamel, and if the gold of the gold plates is alloyed with too much copper, the effect of this is perceived

in injuring the appearance of the enamel. For making colored enamels, either the opaque or transparent enamel serves as a base, and with it is melted a suitable proportion of some metallic oxide as a coloring matter; for a blue enamel, the opaque is used with oxide of cobalt; for a green, oxide of chromium, or binoxide of copper; for a violet, peroxide of manganese; for a yellow, chloride of silver; for a purple, purple of Cassius; and for a black, the transparent enamel is used with mixed oxides of copper, cobalt, and manganese. The different enamels, being prepared beforehand, are when wanted for use crushed to powder, and then kept at hand under water in vessels well covered to protect them from all impurities. The metallic surfaces to be coated are cleaned by boiling in an alkaline solution, and are then washed with pure water. The copper alloy in gold may be dissolved from the surface by boiling in a strong solution of 40 parts of saltpetre, 25 of alum, and 35 of common salt.—In the manufacture of enamelled earthenware, the white enamel is prepared by melting 100 lbs. of lead with 15 to 50 lbs. of tin, and adding to the oxides thus obtained the same weight of quartz sand, and 30 lbs. or thereabout of common salt. The whole being well rubbed together is melted; and though it may appear of dark color, it afterward becomes white when reduced to powder and baked upon the utensils. The proportions of the materials employed are very variable, and other ingredients also are often introduced, particularly oxide of manganese, the effect of which in small quantity is to yield its oxygen to any carbonaceous impurities that may be present, and remove these in the form of carbonic acid from the melted mass. The colored enamels are applied by painting them when finely ground, and mixed with some vegetable oil, as that of spike lavender, upon the white enamel, either before or after this has been once heated, and then baking them in. The ovens for metallic articles are muffles made to slide closely into the furnace, and furnished with a small aperture through which the progress of the operation may be observed.—The enamelling of cast iron cooking utensils was practised at the close of the last century, and a number of different mixtures of the materials employed have since been in use. The use of lead must be carefully avoided in articles of this kind. Vessels of wrought iron are also treated by the same process; and iron pipe for conveying water is advantageously protected by a clean silicious enamel not liable to affect the purity of the water.—The patent right of Messrs. Clarke of England, of 1839, consisted in the use of the following composition and method: 100 lbs. of calcined ground flints and 50 lbs. of borax calcined and finely ground, to be mixed, fused, and gradually cooled. Of this, 40 lbs. are mixed with 5 lbs. of potters' clay, and ground in water to a pasty mass. The vessel, first thoroughly cleaned, is lined with a coating of this about $\frac{1}{4}$ of an inch thick, and left for it to harden in a warm

room. A new coating is next added prepared from 125 lbs. of white glass without lead, 25 lbs. of borax, 20 lbs. of soda in crystals, which have been pulverized and fused together, ground, cooled in water, and dried. To 45 lbs. of this 1 lb. of soda is added, the whole mixed in hot water, dried and pounded. A portion of it is sifted over the other coating while it is still moist, and dried in a stove at the temperature of boiling water. The vessel is then heated in a stove muffle till the glaze fuses. It is taken out, new glaze powder is dusted on the glaze already in fusion, and it is again subjected to heat. The process now employed successfully by Messrs. T. F. Griffiths and co. of Birmingham, of coating the interior surface of wrought iron vessels, consists in first brushing it over, when thoroughly cleaned, with a solution of gum arabic; on this is sifted a fine vitreous powder, consisting of 130 parts of powdered flint glass, 20 $\frac{1}{2}$ of carbonate of soda, and 12 of boracic acid. These are to be well mixed, melted in a glass maker's crucible, and pulverized so as to pass through a sieve of 60 holes to the inch. The article thus coated is placed in an oven heated to from 212° to 300° F., and when dry is removed to another oven, and heated to a bright red till the glass is seen through the aperture to be melted. It is then taken out and annealed. A second application is made if the first prove imperfect. Great care is required that the glassy preparation be protected from mixture with foreign matters, and it is well to glaze the interior of the crucibles before using them. Colored enamels may afterward be applied to the surface of the white coating if desired. By this method iron plates have been made to imitate marble, and mantels for fireplaces, tables, &c., have been produced in New York almost equal in beauty to the originals. There is, however, a tendency in the plates to warp by heat, and is the enamel to scale off; and this latter defect is a serious objection to the enamelled iron cooking utensils sold in the United States. The metal and the glaze do not expand and contract together.—Small articles of enamel, as little toys imitating the figures of birds, &c., and also artificial eyes, are made by melting with the table blowpipe rods or tubes of enamel prepared for this purpose, and shaping them by hand, just as the glass blower works with tubes and rods of glass. Artificial eyes are thus made with great perfection.—Enamelling of slates to imitate marble and malachite was introduced in London not many years since by Mr. G. E. Magnus; and the specimens, then quite novel, exhibited at the great exhibition of 1851, received high praise in the report of the juries, and a prize medal was awarded to the exhibitor. The art was first practised in the United States at Boston, and slates from Wales were imported to be used for this purpose. Subsequently the slates of the Lehigh river were applied to this use in Lehigh co., Penn., and were also sent to Philadelphia to be there enamelled. In Vermont the same business is now carried on at West Castleton, where are exten-

sive quarries of slate, and an establishment of the same kind is in operation in New York. A great variety of useful articles are produced, among which the most important are billiard and other tables, mantels, tubs for bathing, sinks, &c. The slates as received from the quarries are first sawed to proper shape, then planed to uniform thickness, and rubbed smooth with polishing stones. The ground color adapted to the marble it is designed to imitate is then laid on, and after this the variegated colors. The slab is then placed in an oven heated to 200°, and allowed to remain over night. In the morning after cooling it receives a coat of varnish, and is returned to the oven till the next day. Other heatings and varnishings alternately succeed, with rubbing with pumice stone, and a final polishing with pumice stone, rotten stone, and the hand, completes the process.

ENAREA, or ENARYA, a country of E. Africa, W. of Abyssinia, between lat. 6° and 8° N. and long. 33° and 37° E., 15 days' journey from the Nile. It is elevated above the adjacent regions, traversed by a range of hills, in many parts densely wooded, fertile, and watered by several rivers. It is peopled by Gallas, among whom are found a few Mohammedans and Abyssinian Christians. It exports slaves, ivory, gold, coffee, horses, musk, and the skins of various wild animals, in exchange for rock salt (the national currency), beads, daggers, knives, guns, kitchen utensils, copper, and cotton goods. The capital, Sakka, is a considerable place, not far from the banks of the river Kibbe, and is visited by caravans which come from the Nile and from Gondar in Abyssinia.

ÉNAULT, Louis, a French writer, born at Isigny, Calvados, in 1824. After having travelled in various countries and visited the East in 1853, he went in 1854 to Northern Europe. His *Constantinople et la Turquie* appeared in 1855, and his *Voyage en Laponie et en Norvège* in 1857. He has been a frequent contributor to the leading reviews and newspapers of Paris under the *nom de plume* of Louis de Vermont, and has made translations from Goethe's *Werther*, Mrs. Stowe's "Uncle Tom's Cabin," and from the works of Dickens. He is now the literary critic of the *Paris Constitutionnel*.

ENCAUSTIO (Gr. *εν*, in, and *καυστικός*, burning), a term applied to the method of fixing colors upon objects by burning them in. Enamelling in colors is an encaustic process. The word is most commonly used in its application to an ancient method of painting, in which wax was employed with the colors, and a coating of the same material was finally applied to the picture to preserve it from the action of the atmosphere and light. In modern use a peculiar kind of tiles are called encaustic; and by the French the same epithet is applied to preparations of wax used for polishing and protecting the surface of wood. The little that is known of the ancient art of encaustic painting is derived from the mention made of it by Pliny ("Natural History," lib. xxxv. ch. xi.), Marcianus (lib. xvii.),

and Julius Paulus (lib. vii. *et seq.*). Count Caylus called the attention of the French academy of belles-lettres to it in 1755; and M. Bachelier, author of a treatise *De l'histoire et du secret de la peinture en cire*, had produced a picture in wax in 1749. In 1829 M. de Montabert, in his *Traité des tous les genres de peinture*, favorably noticed the process, and M. Durozier of Paris soon after announced that he had perfectly succeeded with the method given by Montabert. The ancient methods appear to have consisted in the use of wax crayons, in which the colors were embodied, and which were used upon a heated surface, the outline of the picture having been first traced. The whole was afterward covered with a varnish of wax melted in and polished. The method of Count Caylus consisted of rubbing and melting wax into the canvas or panel, then coating the surface with Spanish white, and painting upon this with water colors. By warming the picture the colors are absorbed into the wax, and thus protected. Mr. J. H. Muntz recommends waxing only one side of the canvas, painting on the other in water colors, and then melting the wax through to fix them.—ENCAUSTIC TILES consist of a body of red clay, faced with a finer clay, which bears the ornamental pattern, and strengthened at the base with a thin layer of a clay different from the body, which prevents warping. The clay of the body is exposed to the weather for 6 months or more, and is afterward thoroughly worked over and tempered, and mixed with other substances, and at last evaporated at the slip-kiln. From a cubical block of this, formed in the usual method by slapping, a square slab is cut off with a wire, upon which slab the facing of finer clay colored to the desired tint is battled out and slapped down; a backing is then applied in the same way to the other side of the tile. It is then covered with a piece of felt, and put into a box press; a plaster of Paris slab containing the pattern in relief is then brought down upon the face of the tile, and the design is impressed into the soft tinted clay. The hollows thus formed are filled with a semi-fluid clay of a rich or deep color poured into them and over the whole surface of the tile. In 24 hours this has become sufficiently hard to admit of the surplus clay being removed, which is done by placing the tile, still in the box, upon a horizontal wheel, and as it revolves applying a knife or scraper entirely across, so as to rest upon the edges of the box. The surface is thus cut down so as to expose the pattern and the ground. The defects are removed with a knife, and the edges after being squared are rounded off with sand paper. The tiles are kept for a week in a warm room called the green-house, and the drying is afterward completed in another called the hot-house. They are then baked like other articles of pottery, except that double the ordinary time is given to the process, and the oven is left 6 days to cool before the tiles are taken out. They contract in baking from $\frac{1}{4}$ to $\frac{1}{8}$ of their dimensions. The process is supposed to be

nearly the same as that employed in the middle ages in France and England in making pavements for churches, and also for the beautiful pottery called Henry II.'s ware, peculiar to France in the 16th century.—The French apply the term *encaustic* to preparations of wax used for polishing furniture. (See FRENCH POLISH.)

ENCHASING, or CHASING, a process analogous to that of sculpture, being the art of finishing ornamental designs in raised work upon surfaces of sheet metal. When these designs have received their general form by casting, hammering, or other means, the work is finished, all but polishing, with punches or chasing tools. These are of a great variety of shapes and sizes, fitted to correspond with the minute details of the most complex work. Some are grooved and checkered at the ends, and some are nicely polished. They act on a small scale like the dies used for striking coins and medals; and the smallest of them are struck with hammers of diminutive size. In order that the form of hollow articles may not be injured in the operation, these are filled with a composition of melted pitch and brick dust or rosin, or with pitch alone. They are moreover supported upon a sand bag like those used by engravers. Works in copper and brass are sometimes filled with lead to give them a firm support within; but this will not do for articles in gold and silver, which melted lead would seriously injure. The models upon which the sand moulds for receiving objects intended for chasing are prepared, are themselves sometimes chased nearly to the required forms. Excellent specimens of chased work are seen in pieces of ancient armor, and in vases and other ornaments in gold and silver plate. The most beautiful are those by Benvenuto Cellini, who died in 1570. In France the art is practised only in one small district of Paris, and chiefly limited to the production of the richly wrought articles of bronze.

ENCKE, JOHANN FRANZ, a German astronomer, born at Hamburg, Sept. 23, 1791. His father, a clergyman, educated him at home until he was sent to the university of Göttingen. In 1813 and 1814 he served in the Hanseatic legion against Napoleon, and in 1815 he entered the Prussian military service, but afterward accepted a situation in the observatory of Seeberg, near Gotha. In 1825 he was appointed director of the royal observatory at Berlin, and has ever since remained in charge of this institution. He is the author of many valuable memoirs on astronomical subjects, of which the most interesting and important are the treatises published in the *Astronomische Nachrichten*, at Berlin, in 1831 and 1832, upon the comet then called by the name of Pons, the astronomer of Marseilles, who discovered it in Nov. 1818, but now known as the comet of Encke. Since its discovery Encke had diligently applied himself to the determination of its orbit. Making use of the methods of his former instructor, Prof. Gauss, as explained in his work *Theoria Motus Corporum Caeles-*

tium, of calculating an orbit assumed to be elliptical, he showed that its period of recurrence must be about $8\frac{1}{2}$ years, and that it was probably the same comet observed by Mechain in 1786, by Miss Herschel in 1795, and by Pons in 1805. He calculated the effects of the perturbations it would experience from the planetary bodies, especially from Jupiter, and predicted its return in 1822, though it would probably not be visible in Europe. On June 3 of that year it was discovered at the observatory of St Thomas Brisbane, governor of New South Wales. He predicted its return in 1825, and with each reappearance as predicted more elements were afforded for computing its exact orbit. It appeared again Oct. 30, 1828, and Encke was able to fix its orbit as within that of Jupiter, its greatest distance from the sun being 4 times the earth's distance, and its least distance but $\frac{1}{2}$ that of the earth, and its period of revolution 3.29 years. By comparison of the times of its earlier and later apparitions, Encke was afterward led to detect a gradual acceleration of its movement, amounting to about $2\frac{1}{2}$ hours on each revolution. This secular acceleration, never before recognized in the movement of any other celestial body, Encke ascribed to a resisting medium, which sensibly affects a body of the extreme rarity of this comet, which is transparent to its centre, but has no perceptible effect upon the denser planetary bodies. Resistance shortens the time of the revolution by giving greater effect to the attraction of the sun, which then draws the body more forcibly toward itself, lessening the major axis of the ellipse and thus its orbit of revolution. In investigating the perturbing effects of the planets upon this comet, of Jupiter in its aphelion, and of Mercury in its perihelion, he was led to suspect that the mass of the former had been greatly underrated (a fact afterward established by Prof. Airy); and in 1838 Encke proved that Lagrange had ascribed nearly 3 times too great a bulk to Mercury. Encke's explanation of the cause of the acceleration is not universally accepted, though the fact itself is not questioned. Bessel particularly opposed the explanation; by the English astronomers it is more favorably received. Beside these investigations, Encke has improved the theory of Vesta, and published a new method of computing perturbations, especially for orbits considerably elliptical. The planet Neptune was discovered at his observatory by J. Galle, his assistant. Since 1830 Encke has annually published the "Astronomical Year Book," and since 1840 "Astronomical Observations made at the Royal Observatory at Berlin." In 1845 he published dissertations *De Formis Dioptricis*; and in 1846 a treatise "On the Relation of Astronomy to the other Sciences."

ENCRINITE (Gr. *κρίνον*, a lily), a fossil genus of the family *crinoidea* and class *echinodermata*. It appeared among the earliest forms of animal life, its remains being preserved in the rocks of the silurian period. In succeeding formations, nearly to the lias, they are often

abundant that calcareous strata extending over many miles are in great part made up of them. As described by Mr. Miller in his work on the crinoidea, the animals of this family are furnished "with a round, oval, or angular column composed of numerous articulating joints, supporting at its summit a series of plates or joints, which form a cup-like body containing the viscera, from whose upper rim proceed 5 articulated arms, dividing into tentaculated fingers more or less numerous surrounding the aperture of the mouth." In the encrinite the stem is cylindrical; in the kindred genus pentacrinite it is five-sided. The cup-like body is the portion representing the flower of the lily, for which the creature is named. When the tentacula are spread out, the appearance is that of an opened flower; when closed, they represent the unopened bud. The stem served to attach the animal to any bodies in the water, and by the manner of articulation of the plates composing it, it admitted of much motion, swaying back and forth. By this means the head with its tentacula was brought within reach of its prey. The plates of the stem, separating into short cylinders, present the form in which the remains of this animal are most commonly seen. In the marbles used for chimney pieces they are often very abundant, the polished surface presenting some of them of a different color from the ground in longitudinal section, some in oblique conical formed cutting, and some in circular disks, being transverse sections across the cylinder. By the disintegration of the rock containing them, the little joints of the fossil stem frequently fall out, and may be gathered in great numbers. Each has a hole through its centre, admitting of their being strung together. Dr. Mantell states that he has found them preserved in tumuli of the ancient Britons, having evidently been worn by them as ornaments. In the north of England they are called "wheel stones" and "St. Cuthbert's beads," and were formerly used as rosaries. The encrinites are remarkable for the multiplicity of small calcareous pieces, which make up the various parts of the animal—the stem, the parts that may be called the 10 arms, the hands and fingers, and the numerous tentacula which proceed from them all. These pieces, as enumerated by Parkinson in his "Organic Remains," amount to not less than 26,000, thus showing a complexity of structure equal to any that is met with in the nearest living analogues of these ancient animals. The structure of one of the fossil pentacrinites (a genus which began to abound as the encrinite disappeared, and has been represented in some of its species down to the present time from the lias, or indeed in a single species from epochs much more remote), has been cited by Dr. Buckland as "showing an equal degree of perfection, and a more elaborate combination of analogous organs than occurs in any other fossil species of more recent date, or in its living representative." The species thus cited is the Briarean pentacrinite of the lias. The living species is the

pentacrinus caput medusa, almost the only living analogue of the ancient crinoidea. As Dr. Buckland remarks, the primeval perfection of the fossil affords an example at variance with the doctrine of the progression of animal life from simple rudiments, through a series of gradually improving and more perfect forms, to its fullest development in existing species.

ENCYCLOPÆDIA. See CYCLOPÆDIA.

ENDEMIC DISEASES (Gr. *εν*, in or among, and *δημος*, people) are diseases produced by local causes, generally persistent and appreciable, and consequently peculiar to certain climates and localities, during the whole year or at fixed seasons; in the last respect they differ from epidemic diseases, which prevail more or less extensively from accidental, temporary, and generally inappreciable causes. As examples of endemic diseases may be mentioned the cholera of India, the yellow fever of the southern United States, the intermittent fevers of the western states and other marshy districts, the coast fevers of western Africa and Central America, the bronchocele and cretinism of the Alpine valleys, the periodic dysenteries of the East Indies, the yaws of the West Indies, and perhaps the elephantiasis of the blacks in Brazil. Many exanthematous and catarrhal diseases, ordinarily attacking single or few individuals in a community, under the influence of certain ill-understood atmospheric, telluric, or electric conditions, may become epidemic, and affect many persons at a time; the cholera, endemic in India, has raged as an epidemic in Europe and America; and the history of diseases exhibits the occurrence of various epidemics before unknown, appearing without evident cause, defying all treatment, spontaneously disappearing, and not returning afterward. Endemics and epidemics may or may not be contagious (including under that term infection, which amounts practically to nearly the same thing); the endemic dysentery of India, the typhus fever of certain localities, the ophthalmia of Egypt, under favorable conditions, become contagious; the same is true of epidemics of the eruptive fevers, erysipelas, and puerperal fever. The investigation of the causes of endemics and epidemics is one of the most difficult as well as the most important duties of the physician; the lives of thousands may be endangered or saved by the neglect or adoption of proper sanitary, hygienic, and medical treatment; the temperature, electric, and chemical constitution of the atmosphere, the position and nature of the soil, and the food and habits of the people, are principally concerned in the origin of endemic diseases.

ENDICOTT, JOHN, governor of Massachusetts, born in Dorchester, England, in 1589, died in Boston, Mass., March 15, 1665. He was sent out to this country by the "Massachusetts Company" to carry on the plantation at Naumkeag, or Salem, where he arrived Sept. 6, 1628. In April, 1629, he was chosen governor of "London's plantation;" but in August it was determined to transfer the charter and government of the

colony to New England, and Winthrop was appointed governor. In 1636, with the famous Capt. Underhill, he conducted the sanguinary but ineffectual expedition against the Block Island and Pequot Indians. Endicott was deputy governor of the Massachusetts colony from 1641 to 1644, in 1650, and 1654; and was governor in 1644 and 1649, from 1651 to 1654, and from 1655 to 1665. He was bold and energetic, a sincere and zealous Puritan, rigid in his principles, and severe in the execution of the laws against those who differed from the religion of the colony. So averse was he to every thing like popery that he cut out the cross from the military standard. He was opposed to long hair, insisted that the women should wear veils in public assemblies, and did all in his power to establish what he deemed a pure church. In 1659, during his administration, 4 Quakers were put to death in Boston.

ENDLICHER, STEPHAN LADISLAVS, a distinguished botanist and linguist, born in Presburg, Hungary, June 24, 1804, died in Vienna, March 28, 1849. After having received the degree of doctor of philosophy from the university of Pesth, he entered the archiepiscopal seminary of Vienna in 1823, mainly with a view to the study of oriental languages, which he pursued for some years with success. He received the minor clerical orders, but in 1827 resolved to abandon theology for the natural sciences, and especially botany, without, however, giving up his linguistic pursuits. In 1828 he was appointed director of the imperial library of Vienna, in 1836 keeper of the court cabinet of natural history, and in 1840 professor of botany and director of the botanic garden of the university. In his zealous promotion of his favorite studies he soon exhausted the considerable resources which he had inherited from his father. Books, maps, types, seeds, plants, herbaria, and all other materials which were yet wanting at Vienna, and which the government was not liberal enough to procure, he purchased at his own expense. He published the most superbly illustrated works, which owing to their costliness and scientific character found but few purchasers; he even aided others in publishing their works, and gave away whole editions of his own. His map of China, in 24 sheets, may be cited as a specimen of his prodigality. He presented his own choice library and rich herbaria to the state, and distributed rare Asiatic printing types to public institutions. He was equally original and profound in botany and philology. He corresponded with the most eminent savants in every part of the world, and was one of the chief founders of the academy of Vienna, and one of the originators of the *Annalen des Wiener Museums*. He rendered valuable services to the state, for which he received no remuneration, and for 10 years was a constant companion of the emperor Ferdinand V., with whom he used to pass several hours every week. For all this he was rewarded with the paltry title of *Regie-*

rungerath, and had the mortification of seeing the orientalist Joseph von Hammer-Purgstall nominated to the presidency of the academy, an honor to which Endlicher was at least as well entitled. The political turmoils of 1848 placed Endlicher in a precarious position; his sympathies and principles were those of the popular party, while his associations and pursuits bound him to the aristocracy and the conservatives. The untoward turn of political affairs, his pecuniary embarrassments, and the intrigues of enemies drove him to despair, and he died of a broken heart, or as some believe by his own hand.—His works, most of which were published in Vienna, are astonishing for their variety, and are written with equal learning, elegance, and clearness. Those on subjects not connected with botany are: *Examen Criticum Codicis IV. Evangeliorum Byzantino-Corviniani* (Leipsic, 1825); *Anonymi Belæ Regis Notarii de Gestis Hungarorum Liber* (1827); *Prisciani de Laude Imperatoris Anastasii, et de Ponderibus et Mensuris Carmina* (Vienna, 1828); *Fragmenta Theotisca Versionis Antiquissimæ Evangelii Matthæi et aliquot Homiliarum* (edited with Hoffmann von Fallersleben, 1834); *Vom Bruder Rauschen* (with F. Wolf, 1835); *De Ulpiani Institutionum Fragmenta, etc.* (1835); *Catalogus Codicum Manuscriptorum Bibliothecæ Palatinæ Vindobonensis* (1836); *Analecta Grammatica* (with Dr. J. von Eichenfeld, 1836); *Verzeichniss der Chinesischen und Japanesischen Münzen des Münz- und Antiken-Cabinet in Wien* (1837); *Anfangsgründe der Chinesischen Grammatik* (1845); *Die Gesetze des heiligen Stephan* (1849); *Rerum Hungaricarum Monumenta Arpadiana* (St. Gall, 1849).—His botanical works are: *Ceratostachys, eine neue Pflanzengattung aus der Ordnung der Sesameæ* (Berlin, 1822); *Flora Posoniensis* (Pesth, 1830); *Stirpium Pemptas; Meletomata Botanica* (with H. Schott, Vienna, 1832); *Dissingia, Novum Genus Plantarum* (1832); *Prodromus Floræ Norfolkicæ, etc.* (Vienna, 1833); "Miscellaneous Works of Robert Brown," edited in connection with Nees von Eschbeck; *Atacta Botanica, Nova Genera et Species Plantarum* (1833); *Nova Genera et Species Plantarum in Regno Chilensi Lectorum* (with Pöppig, Leipsic, 1835); *Sertum Cabulicum inter Dera Ghazee Khan et Cabul* (with Edward Fenzl, 1836); *Genera Plantarum secundum Ordines Naturales disposita; accedit Supplementum Primum* (1836-'40; one of the most important systematic works yet published); *Enumeratio Plantarum quas in Nova Hollandiæ Ora Austro-Occidentali ad Fluvium Cycnorum et in Sinu Regis Georgii, collegit G. L. B. de Hügel* (with George Bentham, E. Fenzl, and H. Schott, 1837); *Iconographia Generum Plantarum* (1838); *Grundzüge einer neuen Theorie der Pflanzenzeugung* (1838); *Stirpium Australasicarum Herbarii Hügeliani Decades tres* (1838); *Stirpium Novarum Decades* (1839); *Flora Brasiliensis, etc.* (with Ch. Fr. and Phil. von Martius, Vienna and Leipsic, 1840-'46);

Enchiridion Botanicum, etc. (Leipsic, 1841); *Die Medicinalpflanzen der österreichischen Pharmakopöe* (1842); *Catalogus Horti Academici Vindobonensis* (1842-'3); *Mantissa Botanica, sistens Generum Plantarum Supplementa Secundum et Tertium* (1848); *Grundzüge der Botanik* (with Franz Unger, 1848); *Synopsis Coniferarum Sancti Galli* (1847); *Paradisus Vindobonensis* (with Hartinger, 1847); and many minor works in the *Annalen des Wiener Museums*, and in other periodicals. (See also BOTANY, and CHINESE LANGUAGE.)

ENDOGENS (Gr. *ενδον*, within, and *γενναι*, to generate), a class of plants so called because their stems increase in diameter by the deposition of new woody matter in the centre, in contradistinction to exogens, whose stems increase by the formation of a new layer of wood outside of that previously formed, and immediately beneath the bark. In endogens the stem has no medullary rays, concentric rings, or apparent distinction of pith, wood, and bark, but consists of fibres of woody or vascular tissue, distributed with little apparent regularity through the cellular system of the stem. They may be traced from the base of the leaves downward, some passing into the roots, and others curving outward until they lose themselves in the rind or cortical integument, which differs from the bark of exogens in that it does not increase by layers, and cannot be separated from the wood. As the plant grows, new threads or fibres spring from the freshly formed leaves, and passing first down the centre of the stem crowd the old ones out, and are finally directed toward the rind. In some plants the rind, being soft, is capable of unlimited distention; in others it soon indurates, and the stem consequently ceases to grow in diameter. The best example of this class of plants is the palm, whose branchless trunk, rising from 80 to 150 feet from the ground, and terminated by a simple cluster of foliage, has a striking and majestic appearance. The growth of this tree is from the terminal bud, and if the bud is destroyed the tree perishes. In some instances, as in the doum palm of Upper Egypt, and the pandanus or screw pine, two terminal buds appear and branches then shoot forth. The asparagus is an example of endogenous growth. Endogens are monocotyledonous; the veins of their leaves are almost uniformly in parallel lines connected by simple transverse bars; their flowers are trimerous, or have their sepals, petals, stamens, and styles in threes. They luxuriate in hot and humid climates, and they comprise the greater number of plants contributing to the food of man, and but a small proportion of poisonous plants. They are generally shorter lived than exogens, though the dragon tree and others, whose growth is not limited by the hardening of the cortical integument of the stem, may attain a great age. The average age of the palms is perhaps 200 or 300 years.

ENDOR (Heb. home-fountain), a town of Palestine, assigned to the tribe of Manasseh,

situated on this side of the Jordan, to the south of Nain. It was in a solitary valley, not far from this town, that the famous sorceress resided, whom Saul went to consult on the evening before the fatal battle of Gilboa.

ENDOSMOSE (Gr. *ενδον*, within, and *ωσμος*, impulsion), the action exhibited by one of two fluids of different densities and composition in passing through a porous membrane which separates them, till they become both of the same density. Let a solution of sugar in a tube closed below with a slip of bladder tied across the end, and open above, be suspended in a vessel of water. The quantity of liquid in the tube is soon seen to increase by the passing through of the thinner fluid. It will flow over and run down into the outer vessel, and so the action will go on till the two mixtures become uniform. Dutrochet, who first observed this phenomenon, found that the height to which the fluid would rise increased with the density of the thicker fluid. In a tube about $1\frac{1}{2}$ inches diameter and sirup of density 1.083, the fluid rose more than $1\frac{1}{2}$ inches in $1\frac{1}{2}$ hours; with sirup of a density of 1.145 the fluid rose nearly 3 inches; and when the density was 1.228 the rise was 4 inches. A considerable force is exerted in this movement; in sirup of density 1.8 Dutrochet estimated it to be equal to the pressure of $4\frac{1}{2}$ atmospheres. If the flow is drawn inward, the action is called endosmose; if in an outward direction, it is called exosmose. It is supposed to be upon this principle that the sap ascends in trees and fluids are diffused through animal bodies. Liebig, after describing some experiments, in which fluids were made to pass through as many as 9 membranes, to fill the vacant space left by evaporation of another fluid in a glass tube, remarks with reference to the application of the results to the processes taking place in the animal body as follows: "The surface of the body is the membrane, from which evaporation goes constantly forward. In consequence of this evaporation, all the fluids of the body, in obedience to atmospheric pressure, experience motion in the direction toward the evaporating surface. This is obviously the chief cause of the passage of the nutritious fluids through the walls of the blood vessels, and the cause of their distribution through the body. We know now what important functions the skin (and lungs) fulfil through evaporation. It is a condition of nutrition, and the influence of a moist or dry air upon the health of the body, or of mechanical agitation by walking or running, which increases the perspiration, suggests itself." Interesting examples of this phenomenon are seen in the passage of the gases through membranes. If a tumbler, filled with air and covered at top with a thin sheet of India rubber, is placed under a bell glass filled with hydrogen, the gas will soon penetrate the cover and mix with the air; and this action will go on till the India rubber bursts open from the increased bulk of the contents of the tumbler. If the tumbler contained hydro-

gen and the bell glass air, the India rubber would then be pressed in by the escape of the gas, leaving the portion remaining of greatly reduced density.

ENDYMION, in ancient mythology, a shepherd of remarkable beauty, who, according to a Greek legend, retired every night to a grotto of Mount Latmus in Caria. As he slept the goddess Selene (the moon) became enamored of him, and leaving her chariot came down to him. The eclipses of the moon were attributed to these visits. By Selene he had 50 daughters. Jupiter condemned him to perpetual sleep, or, according to other accounts, to 50 years of sleep.

ENFANTIN, BARTHÉLEMY PROSPER, generally known under the name of Père Enfantin, one of the founders of St. Simonism, born in Paris, Feb. 8, 1796. He was the son of a banker, and with his fellow pupils was dismissed from the polytechnic school after March 30, 1814, for having fired on that day on the allied troops. He then became a commercial traveller, and in 1821 member of a mercantile firm in St. Petersburg. He returned to France in 1823, and was converted to the theory of St. Simon by a Jew named Olinde Rodrigues, who had been one of his teachers. After the death of St. Simon, May 19, 1825, Enfantin and Rodrigues began the publication of a journal (*Le producteur*), which was discontinued toward the end of 1826; many persons, who had given their support to it while its discussions were confined to social and industrial interests, having withdrawn as soon as Enfantin assumed the character of a religious innovator, and especially as soon as he was denounced as such by Benjamin Constant. Enfantin, however, continued to advocate his views by lectures and public meetings. The revolution of 1830 favored the movement, which was soon formally organized with Enfantin and Bazard as the chief leaders (*pères suprêmes*), and with the *Globe* newspaper, of which Michel Chevalier was editor, as its organ. A schism, however, soon broke out between the two leaders. Enfantin was a bachelor and a sentimentalist. He divided mankind into two classes, the impulsive and the thoughtful, the former governed solely by transient sentiments and effects, the latter always by abiding principles. In order to harmonize the personal relations between these two classes, he proposed the overthrow of all legislative and social restraint in the sphere of love and affection, and would admit of no other interference with the impulses and emotions of the individual but that of the priest or confessor, who should have full command over the body and soul of his disciples for the purpose of enabling him to control their passions. But in his opinion the priest ought to be a person of great personal attraction, and woman, as a conspicuous representative of the impulsive class of human beings, should take a prominent part in the new movement. Bazard, who was a married man, a person of character and principle, protested against these views, and opposed Enfantin's attempt to convert St. Simon's economical doctrines into a

religious creed. He charged him and his followers with planning a social order founded upon licentiousness; separated from them in 1831, and died a year afterward. His secession was followed by that of the economical and political section of the school. Enfantin, however, persisted in his endeavors to establish a new religion. He addressed his followers (whom he estimated at 40,000 in France alone) with the authority of a superior being set apart by Providence for the purpose of inaugurating a new era for humanity through the emancipation and the agency of woman. He endeavored to find the female Messiah (*femme Messie*) who in his opinion was predestined to bear to him a new saviour of mankind. He enjoined on all his adherents in the different parts of France to aid him in his search for this female; and although his singular theories were attacked by many of his old associates, he continued to make proselytes, the number of his publications increased rapidly, and he sent agents to the principal cities of Europe. He gave splendid entertainments at Paris, which are said to have cost him over \$50,000, in which the purpose of discovering among the women present the long-sought individual was never lost sight of. He procured a loan of \$16,000 for the establishment of industrial workshops, but this amount was not sufficient. They were soon closed, and the *Globe* newspaper was also discontinued for want of funds. The attention of the authorities being at length drawn to his meetings, they were closed in May, 1832. He now withdrew with 40 of his followers, among whom were Michel Chevalier and other eminent men, to the neighborhood of Paris, near Ménilmontant. Here, upon some land which belonged to him, they established a community and spent their time in manual labor and St. Simonian religious ministrations, over which Enfantin presided. Again arraigned by the government, Enfantin appeared in the court with two ladies (Cécile Fournel and Aglaé Saint Hilaire) as his counsel; but they were not permitted to plead his case. The trial lasted 2 days (Aug. 27 and 28, 1832). He was found guilty, and sentenced to a year's imprisonment, but set free after a few months' detention. He subsequently spent 2 years in Egypt, after which he returned to France, devoting himself to agricultural pursuits and officiating as a postmaster near Lyons. By the influence of his former disciples and associates he became in 1841 a member of the scientific board for Algeria. From 1845 to 1848 he was director of the new railway line between Paris and Lyons. In Nov. 1848 he established, in concert with M. Duveyrier, a daily journal, *L'écrit*, with a view of reconciling political reforms with his Utopian views of social relations; but the journal was discontinued in 1850. He again received an appointment in connection with the administration of railways, which he still holds. Among his principal works is *Doctrine de Saint Simon*, which was the joint production of himself and of Carnot, Fournel, De-

veyrier, Bazard, and Abel Transon. It passed through 4 editions from 1830 to 1832, and a new edition appeared in 1854. In his latest work, "Knowledge of Man and Religious Physiology" (Paris, 1859), he still maintains his peculiar religious and social theories.

ENFIELD, a market town of Middlesex, England, on the London and Cambridge railway, 10 m. N. E. from London; pop. in 1851, 9,453. It is noted as the seat of an ancient palace, now half ruined, built in the time of Henry VII., and of the manufactory of the well-known rifles which take their name from this place. The manufactory employs 1,300 hands, and turns out weekly 1,100 stands of arms. The term "Enfield rifle" does not denote any particular improvement, but the result of a series of improvements on the old musket. The guns are made by machinery after the American system, which a commission was sent out by the British government to examine about 1851.

ENFIELD, WILLIAM, an English theologian, born in Sudbury, March 29, 1741, died in Norwich, Nov. 3, 1797. He was a dissenter, and in 1763 was chosen pastor of a congregation in Liverpool, where he remained 7 years, and published some devotional works and 2 volumes of sermons. In 1770 he was elected to the professorship of belles-lettres in the academy at Warrington, remained in this position till the dissolution of the academy in 1783, and was subsequently pastor in Norwich. His biographical sermons and biblical characters are not only valuable as aids to interpretation, but exhibit considerable force of thought and elegance of expression. He published an abridgment of Brucker's "History of Philosophy," and a work entitled "Institutes of Natural Philosophy," and wrote under the signature of X. many articles in Aikin's "Biographical Dictionary." He was also the compiler of "Enfield's Speaker," a very popular collection of pieces for reading and reciting in schools.

ENFILADE (Fr. *enfiler*), in military affairs, a trench or position which may be scoured with shot through the whole length of its line. A trench or parapet is said to be enfiladed when the guns of the enemy can be fired into it in a direction parallel to its length.

ENGADINE, or ENGADIN, or Valley of the Inn, a beautiful valley of Switzerland, situated near the sources of the Inn, at an altitude varying from 3,500 to 6,100 feet above the level of the sea, and extending along the banks of the Inn, through the canton of the Grisons, between two principal chains of the Rhaetian Alps, from the Maloia, which separates it from the picturesque valley of Brigell, to the gorge of Finstermüntz, on the confines of the Tyrol; length, about 45 m.; average breadth between 1 and 2 m.; pop. estimated at 11,000, chiefly Protestants. The tops of the surrounding mountains are inaccessible rocks, and the sides are sometimes covered with glaciers. The valley and the lower part of the mountains are susceptible of cultivation, but are for the most part occupied by forests

or used for pasture lands. The valley was for some time subject to Austria, which lost it in 1623. Most of the male population emigrate at an early age and scatter themselves over all parts of the continent. Some of the higher Alpine pastures of the valley are let every summer to Italian shepherds. The natives speak a peculiar dialect called *Romansh*.

ENGANO, an island of the Malay archipelago, 60 m. S. of Sumatra, in lat. 5° 21' S. and long. 102° 20' E. It is about 30 m. in circuit, of a triangular form, thickly covered with forests, and surrounded by coral reefs. With some small islands adjacent, it has an area of 400 sq. m. The natives, who are genuine Malays, live in conical houses, have neither cattle nor fowls, and seem to subsist wholly on cocoanuts, sugar cane, bananas, and fish. Unsuccessful attempts have been made by the English and Dutch to open an intercourse with these islanders. On the S. E. side of the island there is a safe harbor, formed by a bay protected from the sea by 4 small islands.

ENGHIEN, LOUIS ANTOINE HENRI DE BOURBON, duke of, a French prince, of the Condé family, born in Chantilly, Aug. 2, 1772, executed at Vincennes, March 21, 1804. He received an excellent education, served under his grandfather, Prince Louis Joseph, in the outbreak of the revolution in 1789, and accompanied his father and grandfather into exile. He bore arms against revolutionary France in the famous corps of royalist emigrants commanded by his grandfather, and distinguished himself both by bravery and humanity to his prisoners. On the disbanding of the corps, in 1801, he fixed his residence at a chateau near Ettenheim, in Baden, being impelled to that choice, it is said, by his affection for the princess Charlotte de Rohan, who lived in Ettenheim, and to whom he was perhaps secretly married. Though it does not appear that he took part in any subsequent plots against the French consul, he was generally looked upon as a leader of the *émigrés*, and was suspected of complicity in the attempt of Cadoudal to take Bonaparte's life. The reports of spies sent to watch his movements gave some color to these surmises, for it appeared that he was frequently absent for 10 or 12 days together, at which time it was supposed that he secretly visited Paris. It was thought that an unknown person, apparently of rank, who had been seen to visit Cadoudal at Paris, but who afterward proved to be Pichegru, could be none other than the young duke. Anxious to terrify the royalists by a decisive blow, and to put a stop to their attempts upon his life, Napoleon resolved to seize and execute the duke, and accordingly sent Gen. Ordener with 800 gendarmes to make the capture. The soldiers surrounded the chateau on the night of March 15, 1804, arrested the duke in his bed, and conducted him immediately to Strasbourg, whence he was removed on the 18th to the fortress of Vincennes. He had received warning of his danger from Talleyrand and from the

king of Sweden, through his minister at Carlsruhe, but his escape had been prevented by the delay of the Austrian authorities in forwarding a passport. The prisoner reached Vincennes on the evening of the 20th, and a few hours afterward a court-martial, presided over by Gen. Hullin, assembled in the fortress. A mock trial was gone through, and, without the examination of witnesses or written testimony, the duke was found guilty on various charges of treason, and at once led out to execution. His requests to see the first consul and to be allowed a confessor were both denied. He was shot by torchlight between 4 and 5 o'clock A. M., in the ditch outside the walls, and his body was thrown, dressed as it was, into a grave which had been dug the day before. This tragical end of a young, brave, and amiable prince excited a feeling of horror throughout Europe, though it had its intended effect in putting a stop to plots like those of Cadoudal. Napoleon and his chief instruments took every pains to justify their conduct, and it has never been known who of them was most guilty.

ENGINEERING (Fr. *engin*, an engine), a term applied chiefly to the profession the object of which is the construction of canals, railroads, bridges, aqueducts, and similar works. Those are also called engineers who construct and direct the operation of large engines. Those devoted to the planning and building of fortifications and structures for warlike uses are called military engineers. The title of civil engineer (C.E.) is given to those who are educated to the civil branch of the profession. In France the profession is more strictly divided than elsewhere into many departments. Those engaged upon the public surveys in the interior are called *ingénieurs géographes*; on the coast, *ingénieurs d'hydrographie*; in maritime works and naval architecture, *ingénieurs de la marine*; and civil engineers are *ingénieurs des mines*, or *des ponts et chaussées*. There is also the corps of military engineers, made up of those educated at the *école d'artillerie et du génie*. In the United States the graduates of the military school at West Point are qualified as military engineers, and are also instructed in the principles of the other departments of the profession. The title of civil engineer is legally conferred by the polytechnic school at Troy, N. Y., upon its graduates. In England the institution of civil engineers was established at London in 1828, and the publication of its "Transactions" has served a most useful purpose in disseminating the new data relating to the objects of the profession which are constantly accumulating.—The works of the ancient Egyptians and of some ruder nations indicate surprising acquirements in some departments of the science of engineering. This is exhibited in the moving and raising of the enormous blocks of stone employed in the construction of the architectural monuments of Egypt and of Baalbec in Syria. The canals of the Chinese and aqueducts of the ancient Peruvians are also triumphs of engineering

skill. The works ascribed to Archimedes, undertaken in defence of Syracuse against the Romans in the 2d Punic war, as also his inventions and original demonstrations in mechanical science, entitle him to a high rank as an engineer. Vitruvius was a celebrated engineer, appointed by Augustus to the office of superintending and improving the military engines, and further distinguished as an architectural writer by his treatise (*De Architectura*) upon the building of walls, fortifications, temples, theatres, various hydraulic engines, mills, &c. During the middle ages, and indeed up to the time of the introduction of steam engines, the principal great engineering works, beside the hydraulic operations of the Dutch and the canals constructed in the north of Italy, were in the architectural branch of the profession; and of these the finest examples are the domes of the great churches, as that of St. Mary at Florence, by Brunelleschi; of St. Peter's at Rome, by Peruzzi, San Gallo, and Michel Angelo; and of St. Paul's at London, by Sir Christopher Wren. The introduction of the steam engine, and the great extension of manufactures consequent thereon, opened new fields for the operations of the engineer; and in England particularly the art in its various departments attained a high degree of perfection, exemplified in the numerous admirable canals and railways, the Eddystone lighthouse, the Menai straits bridge, the breakwater at Plymouth, and various other works. One of the most wonderful of these is the bridge across the Tamar, uniting the counties of Devon and Cornwall, constructed by the celebrated engineer Mr. Brunel, and opened in April, 1859; an account of which, too late for the article **BRIDGE**, may conveniently be introduced to conclude the present subject. The bridge, named the Albert viaduct, crosses the Tamar at Saltash, a little above Plymouth, where the estuary is contracted to a width of 910 feet. From point to point on the hills at either side, at the required level of the bridge, the distance is 2,240 feet. This level is 100 feet above the water in order that the bridge shall present no obstruction to the large ships that pass up and down the estuary. Double stone piers 11 feet square, and 17 in number on either side, and varying with the slope of the ground from 20 to 100 feet in height, support the bridge over the margins of the river. To span the river itself without impediment to its navigation was the great difficulty to be overcome. In the middle the water was 70 feet deep, and the bottom was mud and gravel extending 20 feet further down. Here Mr. Brunel caused a cylinder of wrought iron, 37 feet in diameter and 100 feet high, weighing 300 tons, to be sunk upright. The water being expelled by forcing in air under sufficient pressure, the materials at bottom were removed by men working within down to a solid rock foundation; and upon this the central pier of masonry was raised above the surface, the width of this at top being 30 feet. Two tubes of boiler plate iron in arch form

were made ready upon the land to be laid across these openings, each to have one foot upon the pier in the river and one upon the pier on either bank. Each measured 470 feet in length, 17 feet in width, and 12 feet in height; and with the chains to be suspended from it for supporting the roadway, the weight of each exceeded 1,200 tons. Its strength was tested by a weight of 1,200 tons distributed over the whole arch, the effect of which was only to cause a temporary deflection of 7 inches. The tubes, being floated out upon iron pontoons and brought to their places, were raised by hydraulic pressure, the methods employed resembling those adopted for floating and elevating the Britannia tubular bridge. Twice every week the spans were raised 3 feet in one day; and in the intervals the masonry on the land side was built up to support the outer end. The ends in the middle of the river were sustained by temporary blocking each time they were raised, until a height of 14 feet was attained, which admitted the insertion of one of the joints of this length of the great cast iron columns, 4 of which supported these ends. When the arched tubes were raised to the height required, the chains for supporting the roadway were attached, and the work was then soon completed. To stiffen the structure, the parts were strongly bound together with cross ties of wrought iron. The quantity of this metal employed in the work was about 2,650 tons, beside 1,200 tons of cast iron. There were also used about 14,000 cubic feet of timber and 459,000 cubic feet of masonry. When finished, the bridge was tested by a train weighing 400 tons, crossing and recrossing at various speeds. The greatest deflection observed did not exceed $1\frac{1}{2}$ inches. The appearance is said to be tasteful and elegant, though the only object in view was strength and stability. In naval engineering, also, England was preëminent in the construction of the largest ships.—The engineering works of the United States are exhibited in its long lines of railroad, so constructed as to stretch at the least cost over vast and thinly populated areas; in its canals, its dry docks, fortifications, and breakwaters; and more especially in ship-building, which, however, in the United States is not ordinarily treated as a branch of engineering.

ENGLAND (Lat. *Anglia*; Fr. *Angleterre*), a country of Europe, forming with Wales the southern, larger and more important division of the island of Great Britain, and the principal member of the United Kingdom of Great Britain and Ireland; bounded N. by Scotland, E. by the German ocean, S. by the straits of Dover and the English channel, separating it from France by distances increasing westward from 21 m. to 100 m., S. W. by the Atlantic, and W. by St. George's channel and the Irish sea, dividing it from Ireland, and having an average width of about 90 m. It lies between lat. $49^{\circ} 57' 42''$ and $55^{\circ} 46'$ N., long. $1^{\circ} 46'$ E. and $5^{\circ} 42'$ W.; its greatest length N. and S. is 400 m., and its greatest breadth 280 m. Its shape bears some resemblance to a tri-

angle, the apex being at Berwick-on-Tweed, the northernmost point in England, and the extremities of the base at the South Foreland, near Dover, and the Land's End, at the S. W. point of Cornwall. The distance in a direct line from Berwick to the South Foreland is 345 m.; from the South Foreland to the Land's End, 817 m.; and from the Land's End to Berwick, 425 m.; making a total perimeter of 1,087 m., but following the sinuosities of the coast the perimeter will be about 2,000 m. The area of England is 32,590,429 statute acres, or 50,922 sq. m.; that of Wales is 4,734,486 acres, or 7,398 sq. m. The divisions of England are very ancient, the counties being substantially the same now as they were 10 centuries ago, though a few have been made in later times. Each county is subdivided into hundreds, and the hundreds into parishes. London is the metropolis of the United Kingdom, and the other principal places are Liverpool, Manchester, Birmingham, Leeds, Bristol, Sheffield, Bradford, Hull, Southampton, &c. The following table shows the population of the counties in 1841 and 1861, number of inhabitants to the square mile, and county towns:

Wales, which was incorporated with the English

monarchy in the time of Edward I., is divided into 12 counties, with an aggregate population in 1841 of 911,705, and in 1851 of 1,005,721; average number of inhabitants per sq. m. in 1851, 136. Including the army, naval and merchant marine service, the aggregate population of England and Wales in 1851 was 18,004,551, of whom 8,883,298 were males and 9,121,253 females, and the estimated population, June 30, 1857, was 19,304,000. The number of marriages registered in England during the first 9 months of 1858 was 108,571; number of births during the whole year, 655,627; number of deaths, 450,018, an increase of 29,999 from the previous year. The ratio of mortality would thus be about 1 in 48; in 1780 it was 1 in 40, and 1852 it was estimated at 1 in 56.—The most important rivers of England are the Medway, Thames, Stour, Orwell, Great Ouse, Nene, Welland, Witham, Humber, Trent, Ouse, Tees, Wear, Tyne, and Tweed, all of which empty into the German ocean; the Esk, Eden, Lune, Ribble, Mersey, Dee, Severn, Avon, Taw, and Torridge, which empty on the W. coast; and the Tamar, Exe, Froom, Avon (Hampshire), and Southampton water, which flow into the English channel. Many of these have broad estuaries at their mouths, and are navigable by large vessels. The English lakes, though few in number, are famed for their beauty. The picturesque districts of Westmoreland and Cumberland, in which are Ullswater (9 m. long, and from $\frac{1}{4}$ to 2 m. wide), Windermere, the largest lake in England (10 $\frac{1}{2}$ m. long, and from 1 to 2 m. wide), Bassenthwaitewater, Derwentwater, Buttermere, Ennerdalewater, &c., are favorite summer resorts. The sea-coast is much broken, and abounds in fine harbors and roadsteads. On the E. are Herne bay, the estuaries of the Medway, Thames, and Humber, and the Wash, into which empty the Great Ouse, Nene, Witham, &c.; on the W. the broad Solway frith, between England and Scotland, Morecambe bay, the Bristol channel, Bridgewater bay, and the estuaries of the Duddon, Ribble, Mersey, Dee, and Severn; and on the S. Mount's bay, Falmouth harbor, Plymouth sound, Tor bay, the estuary of the Exe, Weymouth bay, Poole harbor, the Solent and Southampton water between Hampshire and the isle of Wight, Portsmouth and Chichester harbors. Near the entrance of Dover strait into the German ocean are the well-known anchorage grounds called the Downs, opposite the towns of Deal and Sandwich. The E. coast presents an alternation of sandy beaches and chalk cliffs, hollowed out in many places into caves, and with several high promontories. The Atlantic tides form a strong current, sweeping S. along this coast, and continually wearing away the limestone cliffs and headlands; the encroachments of the sea have already buried large tracts of land. A submarine forest has been traced along a great part of the coast of Lincolnshire. On the sandy portions of the seaboard the opposite phenomenon is observed; portions of land have here been gained from the water, the town of

Norwich, which is now near the centre of the E. division of Norfolk, having stood in the 13th and 14th centuries on an arm of the sea. The S. coast, from the South Foreland to beyond Folkestone, is characterized by lofty chalk cliffs, which are continually diminishing in height. It then gradually subsides into Romney marsh, W. of which the shore becomes alternately precipitous and flat. The W. is by far the most irregular of the English coasts. It is high and rocky as far as Minehead bay on the Bristol channel. North of the principality of Wales the shore consists of wasting cliffs of red clay and marl, of peninsulas which were probably once more elevated than they are now, of abrupt headlands, and toward Solway frith of sands and marshes. The most mountainous part of England lies N. of the rivers Humber and Mersey, and is traversed N. and S. by a range called the Pennine mountains or the northern range, connected with the Cheviot hills on the Scotch border, and terminating in Derbyshire. The general height of its summits is 3,000 to 3,400 feet. This range is about 60 m. long, and of unequal width, varying from a narrow ridge to 20 m. West of it are the Cumbrian mountains, occupying the central and S. portions of Cumberland, the largest part of Westmoreland, and the N. part of Lancashire. Their highest summits are Seafell (3,168), Helvellyn (3,055), Skiddaw (3,022), and Bowfell (2,911). The Devonian range extends from Somersetshire to the Land's End, and its principal elevations are from 1,500 to 1,800 feet high. Three cross ridges occupy the S. E. part of the kingdom, extending from Salisbury Plain, one S. E. to Beachy Head, another E. to the E. shore of Kent, and the third N. E. into Norfolk. The famous South Downs, 50 m. long and 5 or 6 m. wide, are in the first, and the Surrey hills or downs, celebrated like the former for their sheep pastures, are in the second. The Malvern hills extend over parts of the counties of Gloucester, Hereford, and Worcester. The Cotswold and Stroudwater hills are in Gloucester, and the Chiltern hills extend from Hertford into Oxford. Between these ridges lie many beautiful vales, watered by rivers; other parts of the country spread out in vast plains, such as the plain of York, which extends from the valley of the Tees to the confluence of the Ouse and Trent, a distance of 70 or 80 m., and others abound in rugged and picturesque scenery. Northumberland is in a great degree occupied by moors, which also cover much of Lancashire, Yorkshire, Staffordshire, Cumberland, Westmoreland, and Durham. These are elevated tracts, in most places sterile, heath-grown, or gravelly. Those of the East Riding of Yorkshire alone cover an area of 400 or 500 sq. m. The wolds of Yorkshire, which closely resemble the chalk hills of many other counties, occupy about 500 sq. m.—The distribution of the geological formations through England is curiously connected with that of its inhabitants, their industrial pursuits, and physical condition; all which indeed are in great measure controlled by

the nature of the mineral productions, and of the soil resulting from the disintegration of the rocky strata. Nearly all that portion of England lying E. of a line drawn from the mouth of the Tyne in Northumberland in a southerly direction through the towns of Nottingham and Leicester, thence S. W. nearly to Gloucester, and again S. to Bath, and S. W. to Exmouth, consists of the upper secondary formations, including the oolite, lias, chalk, and greensand; and on both sides of the Thames, widening as the formation extends N. along the coast of Suffolk, is the tertiary group of clays and sands, which constitutes the London basin, and rests in the depression of the chalk. Similar strata hide the secondary rocks over a small area about Southampton and the northern part of the isle of Wight. In Lincolnshire a strip of alluvial skirts the coast, and stretches S., constituting the boggy district of Huntingdonshire and Cambridgeshire. Over this region of secondary rocks the prevailing dip is toward the S. E., so that the lower members of the series are in general met with in passing from the eastern coast westward. They constitute narrow belts, which are traced with great uniformity in their line of bearing, or N. E. and S. W. Thus from Weymouth to the Humber one may continue on that bed of the middle oolite called the Oxford clay, the average thickness of which does not exceed 500 feet. A little further west, from Bridport in Dorsetshire to Flamborough Head on the coast of Yorkshire, the topography, rocks, and soil all designate the chalk formation of earlier date; but west of this, on the line from Lyme Regis to Whitby, the limestones of the lias appears in the general order of older rocks in a westerly direction. Over all this region no mines of coal or of metallic ores are found. The easily disintegrated strata present no bold hills, except in the cliffs of chalk abutting upon the coast, but are spread out in elevated plains, and gentle undulations and hills of smoothly rounded outlines. The calcareous nature of the strata secures fertility to the soil; and the region is distinguished for its agricultural character. West of this, occupying a belt not many miles wide, is the manufacturing district of England, made so by the mines of coal and iron ore which are found along its range. They occur at intervals in isolated basins of moderate area, but remarkably productive in coal by the close grouping together of the beds and the great depths to which they are carried by the steepness of the dip. (See COAL.) These basins are often overlaid in part by the sandstones and marls of the new red sandstone formation, which may be seen resting upon the upturned edges of the strata of the coal formation. The marls afford rock salt and strong brine springs, which have long been advantageously worked in Cheshire, and near Droitwich in Worcestershire. Associated with the salt are also found valuable beds of gypsum. The coal fields are too numerous to be all particularly named. That of Newcastle

extends from the N. E. extremity of England to the river Tees, along the coast of Northumberland and Durham; it is traced further S. to Leeds, but this portion has only the lowest beds, which are of little importance. The Yorkshire and Derbyshire extends south from Leeds to near Derby, and covers in its northern portion a breadth of about 25 m. Some small but very productive coal basins lie S. W. of Derbyshire, of which that near Coventry is the most southern locality of coal in the midland counties. On the N. W. is the Cumberland and Whitehaven coal field, extending along the coast to the north of Maryport; some of its mines have been worked beyond low-water mark, and the convenience of shipping gives a high importance to their products. The Lancashire coal field lies W. of a range of hills that extends along the borders of this county and Yorkshire, separating the two coal fields by the underlying shales and millstone grit of which they are composed. The strata of the coal formation on the west side dip toward the west, and the margin of the field in this direction reaches to Prescott, near Liverpool, and extends N. E. toward Colne. A little beyond the southern extremity of the Lancashire coal field is that which supplies the potteries near Newcastle in Staffordshire, and which, with those referred to as lying S. W. of Derbyshire, make up the central coal district as grouped by Conybeare and Phillips. These include the fields of Ashby de la Zouch and Warwickshire. In the South Stafford or Dudley coal field the coal has been worked in a single bed 30 feet thick, and at one locality it has reached a thickness of more than 45 feet. The western coal district comprises the mines in North Wales, the island of Anglesea, and Flintshire. The middle western or Shropshire district comprises those of the Cleo hills, Colebrook dale, Shrewsbury, &c.; the southwestern district, those of the forest of Dean, South Gloucester, and Somerset, on both sides of the river Avon, and the coal field of the S. coast of Wales, bordering the Bristol channel for 100 m. E. and W., and stretching inland toward the N. from 5 to 20 m. This field is in convenient proximity to the copper mines of Cornwall, the ores from which are transported to the great smelting establishments on tide water near the coal mines. (See COPPER SMELTING.) Much of the coal of this region is semi-anthracite, like that of the Cumberland coal field of Maryland, and some is true anthracite. The latter was first successfully applied upon a large scale to the smelting of iron ores in this district at the Crane iron works. Iron ores abound in the coal measures of this field as well as in many of the others, especially that of Dudley at Wolverhampton, near Birmingham. The same measures also yield the fire clay essential for the manufacture of the fire brick required for the furnaces; the limestone for flux is obtained from the same group of strata and other older formations in close proximity, and the millstone grit which underlies and holds as in a

cup the coal measures furnishes a most durable building stone, also well adapted for withstanding the heat of furnaces. The production of England in coal and iron is stated in the special articles upon these subjects. Beside the coal measures scattered over the area in which they are found, and the newer formations which here and there overlie them, there occur frequent patches, like islands, of rocks of older date, which have intruded through the carboniferous strata and the later formations above them. These are of granite, sienite, and metamorphic slates. Some are basaltic dikes, and one of extraordinary extent appears from under the alluvium on the coast of the German ocean, near Harwood dale, and is thence traced toward the N. W. across the Tees to the western part of Durham. It traverses strata of the lias, oolite, the coal measures, and of the metalliferous or mountain limestone of the lower carboniferous group. Its length is from 50 to 60 m., and in some places it is seen only 25 to 30 feet thick, dipping at a steep angle. The mountain limestone is productive in lead, copper, and zinc ores in 3 districts in England. Veins of galena near Alston moor in Cumberland traverse adjoining beds of limestone and sandstone, yielding well in the former and poorly in the latter. Others are found in the same county, as also in Durham and York in the upper portions of the valleys of the Tyne, the Wear, and the Tees. Pyritous copper is obtained S. W. of Alston moor, and near Elverstone beds of red hematite alternate with those of the same limestone. A second district is in Derbyshire and the contiguous parts of the neighboring counties. Zinc blende is economically worked in this district, which also includes the copper mine of Ecton in Staffordshire. The mineral productions are further noticed in the articles DERBYSHIRE and FLUOR SPAR. The third district is in the N. E. part of Wales, where mines of galena and calamine have long been profitably worked, lying partly in the mountain limestone and partly in older formations. Bordering the coal fields frequently are seen the strata of the old red sandstone and other rocks of the Devonian series; and from beneath these appear the older and lower fossiliferous strata of the silurian and Cambrian formations; they produce little of economical importance. The metalliferous districts of Cornwall and Devon have already been noticed in the articles upon these counties; see also COPPER and TIN, in which the amount of production of these metals is specified. The granitic rocks and metamorphic slates, such as are seen in this portion of England, are repeated in North Wales, where the argillaceous slates are worked in the immense quarries near Bangor. The same rocks occur again in the N. W. part of Yorkshire and Lancashire, and are traced through Westmoreland and Cumberland into Scotland. The granites afford but little good building stone, and there are no important quarries of this rock in England. Building stone of durable character or good qualities in other re-

spects is not readily found in any of the formations; while, on account of the humid atmosphere causing the stones to rapidly disintegrate, the want of durable materials is the more sensibly felt for important structures. The magnesian limestone selected for the new houses of parliament is described under BOLSOVER STONE. It has not proved so durable as was expected, and its decay is so rapid, that it is now being coated with a composition to preserve the surface from further disintegration. England is deficient in fine marbles and in good iron ores. The best of the latter are the hematites; but those chiefly employed in the immense production of iron of this country are the poor argillaceous ores of the coal formation. For making the excellent cast steel, for which English manufacturers are celebrated, the better iron from the magnetic and specular ores of Norway and Sweden is largely imported. The annual produce of salt is nearly 600,000 tons, a large part of which is exported to America. The climate is subject to great variations of heat and cold, and of dryness and moisture, but the winters are not severe for the latitude, and the heat of summer is often relieved by periods of cool weather. The atmosphere is chilly and damp, and particularly moist in the W. counties, but the E. coast is the colder. The mean annual temperature of the S. W. at sea level is about 52° ; at Greenwich, 49° ; at Penzance, $51^{\circ} 8'$. There is thus an increase of mean temperature from N. to S. and from E. to W. July and August are the hottest months; December and January are the coldest, the thermometer in the latter two near London having a mean height of $39^{\circ} 7'$. The W. and S. W. are the most prevalent and constant winds, but a blighting N. E. wind often blows upon the E. coast, doing great damage to the crops and live stock of Norfolk and Kent. Notwithstanding the humidity of the climate, the annual average fall of rain is less than in the Northern United States. For the British islands it is given as 32 inches, while at Cambridge, Mass., it is stated by Prof. Guyot to be 38 inches, and at the Western Reserve college, Ohio, it was found by Prof. Loomis to be 36 inches. The general character of the soil is that of great fertility, though there are 6,000 or 7,000 sq. m. of land unfit for cultivation. The cultivated crops are wheat, oats, beans, barley, rye, turnips, potatoes, clover, hops, flax, &c. Few of the forests are extensive, but the country is well wooded, most of the timber being found in small plantations belonging to private individuals. There are some very large forest lands, however, such as the New forest in Hampshire, Dean forest in Gloucestershire, and Sherwood in Nottinghamshire, which are the property of the crown. The principal trees are the oak, ash, mountain ash, fir, beech, sycamore, maple, poplar, elm, larch, pine, chestnut, horse chestnut, and willow. There are not many indigenous fruits; the pear, crab, medlar, wild cherry, bullace, raspberry, blackberry, gooseberry, currant, strawberry, and cranberry, are the most important species. Foreign fruits,

however, except such as require a powerful sun to bring them to maturity, are found to thrive. Of the small herbaceous plants, beside the common grasses covering the country with verdure which the winter seldom destroys, may be mentioned the daisy, primrose, cowslip, violet, hyacinth, harebell, tamarisk, musk, gentian, foxglove, henbane, hemlock, and nightshade.—The various improvements which modern science has introduced in agriculture are generally adopted in England, and under careful management the land, which once with difficulty supported a population of 10,000,000, now easily maintains nearly double that number. The best systems of drainage are employed, not as formerly in marshy grounds alone, but in nearly all farms. Artificial manuring receives due attention, and steeps which a few generations back would have been thought waste land are now under profitable culture. English husbandry, however, has risen to its present high state very slowly. The farms are small, averaging in England and Wales about 111 acres each, and there are comparatively few landowners, most of the farms being held by tenants at will or by lease. But for this the capabilities of the soil would doubtless be still more thoroughly developed than they are now. The best tilled counties are those of the E. coast. The capital used in tilling and stocking land is about £200,000,000; rent of farms, £30,000,000. Cattle raising is a most important branch of husbandry, and the country has been famous for live stock since the days of Cæsar. Somewhat more than the half of the arable land is used for grazing, the best pastures being found in Buckinghamshire, Kent, Middlesex, and several of the W. and midland counties. In the last are bred good dray horses. Yorkshire is noted for carriage horses, and an excellent breed for farm labor is raised in Suffolk. The English race horse is renowned for speed and beauty. Mules and asses are little used. Lancashire is noted for its long-horned cattle; Northumberland, Durham, Devonshire, Herefordshire, and Sussex, for their short-horned breeds, and Suffolk for its duns. Essex, Cambridgeshire, and Dorset are celebrated for good butter; Cheshire, Gloucestershire, Wilts, other W. counties, and Leicestershire, for cheese. The well-known Stilton cheese is made in the last-named county. The sheep are highly prized for the quality both of their flesh and of their wool. By an estimate compiled from the returns of 10 counties, and a part of Yorkshire, in 1854, it appeared that there were under tillage in England and Wales 12,441,776 acres; under grass, 15,212,203 acres; planted with wheat, 3,807,846 acres; barley, 2,667,776; oats, 1,302,782; rye, 73,731; beans and peas, 698,188; vetches, 218,551; turnips, 2,267,200; mangel wurzel, 177,263; carrots, 12,638; potatoes, 192,287; flax, 10,156; hops, 18,976; osiers, 1,079; other crops, 97,334; in bare fallow, 895,969. Number of horses, 1,050,931; colts, 258,079; milch cows, 1,376,703; calves, 707,192; other cattle, 1,339,270; sheep and lambs, 21,054,812. Many of the wild animals

which formerly inhabited the forests, such as the bear, wolf, wild boar, and wild cat, have disappeared, and the stag, fallow deer, and roe have been preserved only by strict game laws. The other indigenous wild quadrupeds are the fox, badger, polecat, beech and pine martens, otter, weasel, stoat, hedgehog, mole, squirrel, hare, rabbit, dormouse, lemming, shrew, and several varieties of the rat and mouse. More than 270 species of land and water birds have been noticed, of which 20 are birds of prey and 80 belong to the gallinaceous kind. The bustard seems to be the only bird which has become extinct here. Of about 170 species of fish which frequent the coasts, rivers, and lakes, the chief are the herring, pilchard, mackerel, sprat, cod, and salmon. The sea fisheries are chiefly of cod, mackerel, oysters, and lobsters.—The manufactures of England are commensurate with her greatness in other respects. The most important is that of cotton, which employs more hands than any other in the kingdom, and furnishes about $\frac{2}{3}$ of the exports. The principal seats of this manufacture are Lancashire, Cheshire, Derbyshire, and Yorkshire. The number of cotton factories in England and Wales in 1856 was 2,046; spindles, 25,818,576; power looms, 275,590; males employed, 148,354; females, 192,816; total, 341,170. The total amount of raw cotton imported in 1858 was 8,654,633 cwt., of which 5,846,054 cwt. were from the United States, and 2,235,162 cwt. from the British East Indies. Total value of yarns and goods exported during that year, £42,797,000. The chief woollen and worsted manufactories are in Yorkshire, Lancashire, and Gloucestershire, and the value of goods annually produced by them is about £25,000,000. The raw material is mostly of domestic growth, though for some years past large quantities have been imported. The great centres of the hardware manufactures are Birmingham and Sheffield, the former having workshops of iron, steel, copper, and brass, and the latter being famous chiefly for cutlery, agricultural implements, grates, fire irons, &c. The making of linen is carried on to some extent in Leeds and the counties of Lancaster, Dorset, Durham, and Salop. The silk manufacture made great progress under the tariff of 1826, before which date it was unable to compete with the opposition of France and Italy. About 50,000,000 lbs. of leather are made annually. The glove trade of the midland and W. counties is important, the principal establishments being at Woodstock, Worcester, Ludlow, Hereford, Yeovil in Somersetshire, &c. The vast number of establishments engaged in the book and newspaper publishing business gives a strong impetus to the production of paper, the quantity of which made in England in 1858 was 128,929,067 lbs., and in the United Kingdom 176,298,997 lbs. The amount of duty charged on paper in England and Wales during the year ending March 31, 1858, was £920,609, and in the United Kingdom, £1,244,135. Distilling is carried on to much smaller extent than in Scotland and Ire-

land, but the breweries are very numerous, and many of them on the largest scale. The quantity of malt made in England in 1858 was 88,000,871 bushels, and in the United Kingdom, 45,967,461 bushels. The other manufactures comprise hats, glass, pottery, soap, lace, &c. Ship building is also a prominent branch of industry. The number and tonnage of the vessels built and registered in the United Kingdom in 1857 are stated in the subjoined table, which we give, because of the impossibility of distinguishing those properly belonging to England alone; and this remark also applies to various other statistical statements contained in this article:

Materials.	Sailing.		Steam.		Total.	
	Vessels.	Tonnage.	Vessels.	Tonnage.	Vessels.	Tonnage.
Timber.....	1,019	184,908	78	2,978	1,095	187,181
Iron.....	88	18,351	155	49,940	193	68,291
Total	1,050	197,554	228	52,918	1,278	250,472

The exports of British and Irish produce and manufactures in 1857 and 1858 were as follows:

The commerce of England, until the rise of the trading and maritime power of the United States, had long been without a parallel. Her situation is in the first degree favorable for such pursuits; the hardihood, industry, and enterprise of her people have turned her natural advantages to account, and there is no part of the world accessible to her merchants with which she has not established commercial relations. With Ireland she has a trade in grain and provisions in exchange for manufactured goods; from N. Europe she receives timber, iron, flax, hemp, pitch, tallow, potash, and wheat; from central Europe, agricultural produce, silk, linen, lace, gloves, timber, flax, wine, and gin; from S. Europe, wine, brandy, fruit, drugs, silk, &c.; from the United States, cotton, tobacco, rice, and flour, the imports thence being considerably inferior in value to the exports thither; from South America, hides, skins, indigo, cochineal, and bullion; from Asia, tea, coffee, sugar, indigo, drugs, cotton, piece goods, and ivory; from Africa, drugs, ivory, teak wood, and hides. Manufactured goods are the staples furnished by England in exchange for all these commodities. The following table shows the commerce of the United Kingdom for 4 years ending with 1857:

Years.	Imports.	Exports.		
		Produce and manufactures of the United Kingdom.	Foreign and colonial merchandise.	Total exports.
1854	£152,591,518	£297,184,726	£ 6,648,975	£115,538,704
1855	146,680,323	86,668,065	31,012,356	116,701,041
1856	173,544,154	115,828,948	28,898,405	189,390,349
1857	187,846,285	123,066,107	22,358,785	145,419,373

The imports into the United Kingdom during the 11 months ending Nov. 30, 1857 and 1858, were as follows:

The exports in 1858 were thus distributed: cotton, woollen, silk, and linen yarns and manufactures, £63,667,000; hardware and cutlery, £3,280,000; machinery, £3,604,000; iron, £11,238,000; copper and brass, £2,854,000; lead and tin, £2,288,000; coals and culm, £2,052,000; earthenware and glass, £1,721,000; beer and ale, £1,852,000; butter and cheese, £632,000; soda, £818,000; salt, £288,000; spirits, £307,000; leather manufactures, £1,011,000; printed books, £890,000; stationery, £804,000; plate and watches, £254,000; furniture, £258,000; soap and candles, £367,000. The imports of bullion in 1858 were: gold, £22,793,000; silver, £6,700,000; total, £29,493,000, of which £2,066,000 was from Australia, £6,885,000 from Mexico, South America, and the West Indies, £4,611,000 from the United States, £2,512,000

from Russia, Hanse towns, Holland, and Belgium, and £3,733,000 from France; exports: gold, £12,565,000; silver, £7,063,000; total, £19,628,000, of which £10,921,000 was to France, £5,230,000 to India and China, and £1,569,000 to the Hanse towns, Holland, and Belgium. The entrances, clearances, and tonnage of vessels engaged in the foreign and coasting trade of the United Kingdom in 1858, were as follows:

The registered shipping of the United Kingdom, Dec. 31, 1857, was thus distributed:

Division.	Sailing.		Steam.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
England and Wales...	19,117	3,298,173	1,368	296,515
Scotland	3,314	558,623	294	60,664
Ireland	3,075	218,450	151	33,638
Total	24,406	4,075,245	1,813	415,963

The ocean steam navigation of England is incomparable, and her lines of steam packets may be said to perform the mail service of the world. Steam vessels of iron are now extensively built. The means of internal communication are superior to those of any other country. It is just a century since the English began to make good roads, though turnpikes were set up a hundred years earlier. The total length of all roads in England and Wales, exclusive of paved streets and roads in towns, is about 100,000 miles; of the latter, 30,000. The canals of England are next in importance to those of Holland, and were commenced in the last century. The railway system was introduced in 1825. The following table shows the length of railways in the United Kingdom, Dec. 31, 1857, and their receipts for the previous 6 months:

Division.	Miles of railway open.	Receipts from passengers.	Receipts from freight.
England and Wales...	6,773	24,890,581	25,230,046
Scotland	1,350	592,077	780,447
Ireland	1,070	422,636	178,735
Total	9,093	25,911,244	26,189,219

The number of passengers carried during the same period was, in England and Wales, 62,927,763; Scotland, 3,153,825; Ireland, 4,752,427;

total, 75,834,014. There were 998 m. of railway in course of construction, but not begun, and 3,554 authorized.—The total number of letters delivered in 1858 was, in England, 438,000,000 (nearly $\frac{1}{2}$ in London and suburbs); Ireland, 44,000,000; Scotland, 51,000,000; total, 528,000,000, showing an increase of 19,000,000 as compared with 1857. The number of newspapers posted in 1858 was 71,000,000. The persons employed in the post office on Jan. 1, 1859, numbered 24,372. The public institutions of charity, of learning, of the arts, of education, and of religion, are in great number and of high repute. Every considerable town has its hospitals, many of which are liberally endowed, its free schools, mechanics' institutes, &c. The principal cities possess galleries of art, and several have valuable libraries. Compulsory provision for the poor has long been established in England. The whole country is divided into poor law unions, over which are guardians elected by the rate payers. During the quarter ending Dec. 31, 1858, there were, in 627 unions and single parishes, 826,655 paupers in receipt of relief, a decrease of 75,377 from the corresponding period of 1857. The number of pauper lunatics in asylums, hospitals, and licensed houses, Jan. 1, 1858, was 17,572, and probably 12,000 or 13,000 more were supported by the poor law guardians in workhouses, or with private persons. The total amount expended by the poor law boards in England and Wales during the half years ending March 25, 1857 and 1858, was £2,043,977. The number of charitable institutions other than schools, in London alone, in 1853, was 580, and the amount expended by them during the year, £1,805,835.

—England has done much for the cause of education, but not so much as should have been done by so old, wealthy, and humane a nation. The principal universities, which have existed for many centuries, are among the most venerable monuments of the middle ages; and as much of the illiberality that once was conspicuous in their government has disappeared, it may be believed that their future will be as brilliant as their past has been useful. Among the higher institutions of learning are the universities of Oxford, Cambridge, and Durham; University college and King's college, London (the last 2 founded for the purpose of cheapening and popularizing academical instruction); college of preceptors, London; Owen's college, Manchester; Manchester New college; Queen's colleges, Birmingham and Liverpool; St. David's college, Lampeter; royal agricultural college, Cirencester; beside good foundation schools at Winchester, Eton, Manchester, Great Berkhamstead, Warrington, Shrewsbury, Birmingham, Tunbridge, Westminster, Highgate, Bedford, Ipswich, Repton, Rugby, Harrow, and London. The great public schools of Eton, Westminster, Harrow, Winchester, St. Paul's, the charterhouse, and merchant tailors' school, are of the highest reputation, and have educated many of the distinguished men of England. The University

college and King's college, established in the capital, have not only proved useful institutions themselves, but their foundation has had a good effect on the old universities. There are 804 collegiate and grammar schools, and 1,607 other schools, the annual value of the endowments of which is estimated at £500,000, but not $\frac{2}{3}$ of this amount is made available for the purposes of education. Though parliament has sought to investigate the causes of this breach of trust, no correction of the evil has been made. The number of schools of the common class, for the diffusion of popular education, was, in 1851 (including both public and private schools), 44,836. The private schools were 29,425, of which only $\frac{1}{4}$ were ranked superior. Of the inferior schools, nearly $\frac{1}{4}$ of the whole, the returns of 708 were signed by the master or mistress with a mark; and the same strange fact occurred in the returns of 85 public schools, most of them having endowments. The number of scholars attending day schools in 1851 was 2,144,378; Sunday scholars, 2,407,642. Though little has been done for general education, compared with what has been effected in some other countries, yet the improvement has been great within 60 years, the present generation of Englishmen being in every respect more enlightened than their ancestors. Government has done but a small part in the work; and it was not until 1833, when Lord Grey was at the head of that whig ministry which carried through the reform bill, that the first public grant was made. It was £20,000, which was continued for 5 years, when the amount was raised to £30,000. From time to time it was increased, until in 1853 it reached to the sum of £260,000. The amount expended in Great Britain for education grants in 1857 was no less than £559,974, of which £119,664 was spent in building, enlarging, repairing, and furnishing elementary and normal schools, and £57,221 in annual grants to training colleges. Of the amount expended the following were the principal recipients in England:

Church of England schools.....	£257,597
Wesleyan schools.....	82,890
British and foreign school society.....	50,022
Parochial union schools.....	5,224

The grant to Roman Catholic schools in Great Britain was £25,894. Among the educational grants in 1858 were £663,435 for public education in Great Britain, £83,730 for the department of art and science, and £3,654 for the university of London. The total amount granted for Great Britain and Ireland was £1,126,607. The grants to elementary schools in England and Wales, the channel islands, and the isle of Man, from parliamentary votes, from 1833 to 1857 inclusive, amounted to £2,055,642 5s. 4d. The subject of national education is increasing in interest in England, and it is supposed that determined efforts will be made to establish some system of general application, at no very distant day. The question of religion is that which causes the chief difficulty in the way of comprehensive working on the part

of the government. The dissenters believe that any plan which the government might adopt would be too much under the dominion of the established church, and they not only discourage state interference, but some of them object to all kinds of aid from the state, deeming the voluntary principle the proper basis of action, as well in the support of schools as in that of religious worship. Sectarian influence everywhere exhibits itself in the educational movements of England, and the exertions of the dissenters consequent on the government's supposed desire to favor the church's claim to superintend popular education have done much to spread knowledge. Rivalry has been productive of good in this instance, as it has been in some other. It is not possible to see what will be the ultimate course adopted, but the practical character of the nation cannot fail to devise some plan that shall prove acceptable to the great body of the people. The educational movement has among its supporters men of all parties, and of various religious views, the opinion prevailing that upon the elevation of the people through its success depends their own private individual happiness, and the increase of the strength and reputation of the British empire.—The established religion is that of the church of England, which will be treated in a separate article. The dissenters constitute some of the most respectable religious bodies in the world. They consist of Presbyterians, Independents, Baptists, Friends, Methodists, Unitarians, Bible Christians, Moravians, and some others. The Presbyterians, Methodists, and Baptists are severally divided into a number of sects. The Catholics are not numerous, but among them are many old and wealthy families. The Jews are few in number, but since July 23, 1858, when they were admitted to sit in Parliament, they have enjoyed all civil rights. The utmost religious liberty exists.—The number of journals of all descriptions (exclusive of monthly and quarterly reviews) published in 1858 was, in England, 538 (129 in London); Scotland, 181; Wales, 22; total, 691.—The government is a limited hereditary monarchy, the supreme power being vested in a king or queen and ministry, and a parliament composed of lords and commons, the former sitting chiefly by hereditary right and the latter by popular election. A previous knowledge of English history being required for a comprehension of the changes and present state of the English constitution, we shall refer the reader for an account of the latter to the concluding part of this article.—The following tables show the revenue and expenditure of the United Kingdom for the fiscal year ending March 31, 1858:

REVENUE.	
Customs.....	222,102,104
Excise.....	17,222,000
Stamps.....	7,415,710
Taxes.....	8,122,000
Property tax.....	11,200,114
Post office.....	2,922,000
Crown lands.....	270,000
Miscellaneous.....	1,204,000
Total.....	267,222,000

EXPENDITURE	£	s
Interest and management of the funded debt	23,573,978	06
Unclaimed dividends paid	88,580	18
Terminable annuities	2,979,965	17
Interest of exchequer bonds, 1854-'5	210,000	00
Interest of exchequer bills, supply	774,648	06
Redemption of exchequer bonds	2,000,000	00
Civil list	401,257	11
Annuities and pensions	834,997	07
Salaries and allowances	157,548	13
Diplomatic salaries and pensions	158,938	18
Courts of justice	568,224	18
Miscellaneous charges on consolidated fund	178,029	17
Compensation to Denmark for sound dues	1,125,206	00
Army	12,915,156	16
Navy	18,590,000	00
Persian expedition	900,000	00
War with China	590,698	00
Miscellaneous civil service	7,227,719	10
Salaries, &c., of revenue departments	4,853,988	10
Redemption of the £5,000,000 loan	250,000	00
Total	70,878,859	02

The total revenue for the year ending March 31, 1859, was £65,477,284, and the expenditure £64,663,882. The total public debt of the United Kingdom, March 31, 1857, was : funded £779,701,417, unfunded £24,032,541, total £803,733,958; of which the permanent debt of Great Britain was £736,009,272, and that of Ireland £48,692,14. The funded debt of the United Kingdom was £757,951,281 in 1854, and on March 31, 1858, had increased to £779,225,000, principally in consequence of the Russian war which broke out immediately after the former date. The standing army consists of 222,874 men, including those dispersed in the colonies and India. Of this number 20,067 are cavalry, 23,842 artillery, and 179,465 infantry. The navy, in July, 1858, comprised 244 sailing vessels of various kinds with an armament of 8,716 guns, and 294 steam vessels carrying 7,075 guns (total 538 vessels, 15,791 guns), beside 160 gun boats and 120 vessels for port service. The government has fine dockyards at Deptford, Woolwich, Chatham, Sheerness, Portsmouth, Devonport, and Pembroke, a naval academy at Portsmouth, a military academy at Woolwich, and a military college at Sandhurst.—The judicial system of England comprises 4 superior courts: the high court of chancery, the court of exchequer, the court of king's bench (termed during the reign of a queer the court of queen's bench), and the court of common pleas. The court of king's bench is the supreme court of common law, and takes cognizance of both civil and criminal causes, and to it can be removed by writ of error the judgments of all other English courts of record. It consists of a chief justice and 4 other justices. The court of common pleas likewise consists of 5 justices, and takes cognizance of civil cases between subjects. The court of exchequer consists of a chief baron and 4 other barons; it is both a law and an equity court, trying all revenue questions and many other cases. The judges of these 3 courts are called the 15 judges of England. There are 4 terms in the year of about 3 weeks each, during which the 3 courts sit at Westminster for the determination of all questions of law. Twice a year 14 of the judges make circuit through England and Wales to try causes in the country. By act of

parliament in 1846 and by several subsequent acts a system of county courts has been formed, giving increased facilities for the prompt and inexpensive collection of small debts. The judges of these courts are appointed by the lord chancellor, and must not exceed 60 in number. They have jurisdiction over districts arranged with regard to convenience, and not always bounded by county lines, counties in some cases being divided to form them. Demands not exceeding £50 are brought before these courts, the judges of which determine all questions whether of law or fact unless a jury be summoned, which is done at the request of either plaintiff or defendant. The number of the jury is 5, and a unanimous verdict is required. A court of general quarter sessions of the peace is held 4 times a year in every county, its jurisdiction extending to all felonies and trespasses, but the capital cases generally are remitted to the assize. The counties are governed by the lord lieutenants and sheriffs, and they have also their justices of the peace appointed by the crown, clerks of the peace, and county coroners. The character of the English courts is very high, and has been so ever since the revolution. The criminal code of England, which was for a long time excessively severe, has been greatly improved of late, and with its improvement, crimes, especially acts of violence, have signally decreased. The number of persons committed to prison in England and Wales in 1857 was, males 107,384, females 84,586, total 141,970. Of 54 sentenced to death (20 for murder), 13 were executed, the punishment in all the other cases being commuted. The greater proportion of convicts sentenced to long terms of detention were formerly transported to penal colonies or confined on board hulks, but prisons are now established at home capable of receiving all. The principal prisons are those of Millbank, Pentonville, Portland, Dartmoor, Portsmouth, Chatham, Brixton, Parkhurst, Fulham refuge, and a hulk at Portsmouth. There were also at the beginning of 1858, 40 certified reformatory schools in England with 1,866 inmates, and 22 in Scotland. The police force of England, Sept. 29, 1857, was 19,187, and the cost of maintaining it during the year ending at that date was £1,265,579.—The history of England begins shortly before the commencement of our era, when (55 B. C.) Cæsar first invaded the island, landing near Deal or Walmer. Britannia and Albion were the names by which it was known to the Romans. The Phœnicians had known the island, and so had the Carthaginians and Massilians, and all of them are supposed to have traded with it directly or indirectly, the Phœnicians especially, for tin. The interest that Cæsar's invasion caused at Rome, among the best informed men there, shows how little was really known concerning the country, and even for a long period afterward it was regarded as cut off from the rest of the world. He made little impression on it, and his invasion probably met with more resistance than is commonly supposed. Augustus proposed

an expedition to Britain, but never attempted it. Caligula also threatened invasion, and triumphed without executing it; but it was reserved for Claudius to begin the work of real conquest (A. D. 43). During the next 40 years the conquest of south Britain was completed, many generals being employed, including Aulus Plautius, Vespasian, Suetonius Paulinus, and Agricola. The main divisions of the country were *Britannia Romana*, embracing England and Wales, and which had been entirely subdued; and *Britannia Barbara*, which at first included all the country to the north of the wall of Hadrian, but later only what was to the north of the wall of Antoninus. This region defied all the efforts of the Roman arms. The other was in a very flourishing condition, and at a later period was divided into 5 provinces, named *Britannia Prima*, *Britannia Secunda*, *Maxima Cæsariensis*, *Maxima Flaviensis*, and *Valentia*. The country suffered with the rest of the empire from the invasions of barbarians, and was abandoned by the Romans in the earlier part of the 5th century. The Britons then became independent, and displayed much energy and spirit in contending with the invaders. They were less successful in their endeavors to establish a body politic, and the island was distracted by contentions and civil wars. The disturbed state of the country was favorable to the incursions of the Picts and Scots, when a few Saxons, said to have been exiles, arrived in the isle of Thanet. They were but 300, and were led by two brothers commonly called Hengist and Horsa. They were, it is probable, on a piratical excursion. The story that they came by invitation is unfounded, and probably originated in the fact that other Saxons were subsequently invited to Britain. The British chiefs resolved to hire their visitors as soldiers, according to a not uncommon custom. They chastised the Scottish invaders, and when the Saxon leaders proposed sending for more of their countrymen, in order that their defensive measures might be more extensive, the proposition was readily received, and numbers of Saxons, Angles, and Jutes arrived in the country. At first these strangers proved good friends to the Britons, but when they had conquered the other barbarians they took Britain for their reward. This, however, was not effected without a bloody contest, in which the Britons evinced great bravery, and at one time are said to have expelled their false allies. The history of these times is little better than fable, and the very names of Hengist and Horsa are perhaps as mythical as those of Romulus and Remus. The most that is known is, that certain Germanic invaders subdued the greater part of Britain, and laid the foundation of that England which has occupied so large a space in the history of the world for so many centuries. We know the result, but of the processes we know next to nothing. These invaders appear to have belonged substantially to one race, but they had strong points of difference, which were particularly prominent as between Saxons and Angles. Lappenberg, in summing

up the Saxon conquest, says: "So trivial, and yet more uncertain, are the accounts left us of the conquest of a great kingdom by the barbarous dwellers on the German ocean, and of the spoliation perpetrated among structures and other property, the fruits of Roman civilization, on a people accustomed to servitude, who knew but little how to use them, and still less to defend them." Kemble expresses the opinion that the Anglo-Saxon kingdoms for a long period were only so many camps planted upon an enemy's territory, and not seldom in a state of mutual hostility. One effect of this German conquest was to cause Britain to revert to heathenism, and one of the fairest provinces of Christendom was apparently lost; but in the pontificate of Gregory the Great it was recovered, and the work of Saxon conversion commenced, under the guidance of Augustin. The octarchy, improperly called heptarchy, dates from A. D. 560. Turner rejects the statement that it was by Egbert that the name of England was formally bestowed upon Germanic Britain, but Lappenberg's arguments in support of it seem to be conclusive. It was in Egbert's reign, the first 3d of the 9th century, that the Northmen first appeared in force in England; and it shows the vitality of the old British race, that numbers of them joined the invaders. There had been previous attacks, but this was the most serious; it was unsuccessful, and the Britons who had risen were severely punished. These invasions were constantly renewed, the Northmen and Danes being the terror of all peoples who could be reached from the sea. Large portions of England fell into their hands. Much of Alfred's reign was passed in contests with them. The fortune of these wars was various, but even the victories of the Anglo-Saxons cost them dear; yet it is probable that the general result was good, and that the infusion of new blood into England prevented the country from degenerating rapidly, and gave to it a new life. Much of what is called Saxon is of Danish origin; but it should be mentioned that the Danes and Saxons were substantially of the same race, the differences that there were being in favor of the former. A Danish dynasty was established in the early part of the 11th century, and the name of Canute, or Knud, is high on the list of England's sovereigns. The Saxon dynasty was restored in 1042, in the person of Edward the Confessor, on whose death the throne was conferred on Harold, son of Earl Godwin, a great Saxon statesman. His reign was destined to a sudden and tragical termination. An event was impending over England which was to color her history forever. The Normans, descendants of those Northmen who had settled in *Neustria* (N. W. France), had obtained considerable influence in England in the Confessor's time, and were indeed the leading race of the West. William, duke of Normandy, claimed the throne of England through his great-aunt, a title utterly worthless. Neither William nor Harold had

any legitimate pretensions to the throne, but Harold had the support of the English nation, and William assembled a powerful army to enforce his claim. The support the duke received from his own subjects was reluctantly given, but the promises of spoil he held out attracted to his service a large number of adventurers from different parts of Europe, so that he was enabled to land 60,000 men in England. Harold, who had just defeated an army of Norwegian invaders, met the Normans at Hastings, where he lost his life and his kingdom, Oct. 14, 1066. William's victory was complete, and the Normans and other adventurers soon became masters of all England. Saxons and Danes were involved in common slavery. The victor introduced the feudal system into England. It is probable the extent of the Norman spoliation has been much exaggerated, but that the natives were reduced to a state of political bondage admits of no doubt whatever. The very name of Englishman was made odious. A foreign rule was established over England, and it was not until 7 generations from the conquest had passed away that the distinction between Norman and Saxon was nearly obliterated. It did not disappear altogether until a much later period, but it ceased to influence legislation in the last days of the 13th century, or soon after that time. The Norman line gave 3 sovereigns to England: William I., William II., and Henry I. The death of the latter, in 1135, was followed by the reign of Stephen of Blois, his nephew, and by the wars between that king and the adherents of the old dynasty. Henry I. left an only daughter, Matilda, married first to the emperor of Germany, and then to Geoffrey, earl of Anjou, by whom she had that prince who became Henry II. of England in 1155. England suffered terribly in the contest between Stephen and Matilda, the rightful heiress to the crown, who was supported by a powerful party. Henry II. became king in consequence of an arrangement with Stephen, who had lost his only son Eustace; but the treaty was really the work of the barons, who had risen to high power during Stephen's reign. The young king was the founder of the royal family of Plantagenet, which held the English throne 380 years, and from him, in direct line, Victoria is descended. He had Saxon blood, his great-grandmother on the island side being a Saxon princess, and having in her veins the blood of Alfred. There have been few abler monarchs than Henry II. His foreign possessions were vast. He was duke of Normandy and count of Anjou, and having married Eleanor of Aquitaine, was also duke of Aquitaine and count of Poitou. Maine belonged to him. He undertook the conquest of Ireland. Had it not been for his dispute with Becket, and the domestic troubles that happened at a later period of his life, he might apparently have conquered the whole of France. The crusades, too, had an effect prejudicial to his interests. He died in 1189, and was succeeded by Richard I. (Cœur de Lion), who was more a crusading chief than a

king, and more a knight-errant than either. The English are proud of him, yet he was a Frenchman, could not speak the language of the island people, and kept out of England whenever he could. His brother and successor, John, ascended the throne in 1199. It is from his reign that England dates the renewal of her existence as a nation. John was one of the weakest and most wicked of kings; he is one of the few men, eminent either from talent or position, who, after having been long regarded as monsters, have had nothing said in their favor by modern writers. The character and conduct of Richard III. have been defended with plausibility; Henry VIII. has been pronounced almost a perfect monarch by one of the great lights of this age of historical criticism; but John is held to be as bad now as he was in those times when Shakespeare furnished such life-like portraits of English kings. He is the same "trifler and coward" to posterity that he was to his contemporaries; and the highest authority assures us that his follies and vices were the salvation of England. His French rival, Philip Augustus, was an able statesman. Their contests were ruinous to John as a continental sovereign. Normandy, Brittany, and Anjou were lost. The English Plantagenet had little more than England for his dominion. His continental possessions were all to the south of the Loire. The insular Normans were separated from the continental Normans, and were compelled to have the same interests with the mass of the people. From this came the series of events that led to the concession of the great charter, June 15, 1215. John was involved in disputes with the pope, to whom he afterward resigned his kingdom, and he is said to have offered to turn Mussulman if he could obtain Saracenic aid from Spain against the barons. In a contest with France his troops shared in the loss of the battle of Bovines. The barons called Louis of France to their aid, and he at first was successful, but evincing a partiality for his countrymen he lost ground, many of his first supporters joining John, who was about to fight him, when he died, Oct. 17, 1216. He was succeeded by his eldest son, Henry III., a boy of 9 years. The government was conferred on the earl of Pembroke, who succeeded in compelling the French to make peace and to leave the country. On Pembroke's death power passed to the hands of Hubert de Burgh and the bishop of Winchester, but the former was soon compelled to resign it. The reign of Henry III. is the longest in English history save that of George III., and it was passed in constant troubles. The favor shown to foreigners caused much irritation. There were frequent disputes with the barons, which led to important consequences. Under the lead of Simon de Montfort, earl of Leicester, the barons defeated the king at Lewes, in 1264, and took him captive, and the next year, under Leicester's rule, the first English parliament was assembled. The same year Leicester and his party were destroyed by Prince Edward. The royal author-

ity was for a time reëstablished, and the prince departed to join the last crusade. Henry's weakness encouraged his enemies, and the country was relapsing into confusion, when he died in 1272. Edward I. ascended the throne without opposition, and proved himself an able and unscrupulous ruler. He was a good sovereign for England, founding permanent legal institutions which have ever since been spoken of with respect, and lessening the public expenditure; but toward foreigners he was faithless and cruel. He conquered Wales and murdered its princes. That country was annexed to England, the king conferring the title of prince of Wales on his son and heir, which has ever since been borne by the eldest son of the sovereign of England. He sought to conquer Scotland, and at one time appeared to have succeeded, but the resistance of the Scotch, first under Wallace, then under Comyn and Fraser, and finally under Bruce, saved their country from becoming an English dependency. Edward was involved in a war with France, which had seized Guienne, one of the few remaining possessions of the English on the continent, but which was restored under papal mediation. His wars made him dependent on parliament, the power of which was much increased in his reign, the commons first sitting in a separate chamber in 1295. He violated the great charter, and for a time showed every disposition to reign arbitrarily; but the opposition he experienced was not to be overcome, and he gave way before it. It was while marching to meet Bruce in Scotland that Edward I. died, on July 7, 1307. His successor, Edward II., was a weak prince, who was unable to comprehend or to accomplish his father's designs. He was governed by favorites, whose insolence provoked the barons, by whom the chief of them, Gaveston, was put to death, in 1312. The king was induced to lead a great army to Scotland in 1314, which was completely defeated at Bannockburn, an event that established the Scottish nation and the throne of Bruce. At the instance of Edward's queen, Isabella of France, parliament deposed the king, who was soon afterward murdered, in Sept. 1327. The government was nominally in the hands of Edward III., a boy of 15, but in reality it was wielded by Isabella and Roger Mortimer, her paramour. These rulers were unpopular, and their unpopularity was increased by a treaty which they made with Scotland in 1329, renouncing all claim to superiority over that country. Mortimer showed himself able and unscrupulous, and the young king had to conspire against him. The queen mother and her lover were seized, and the latter was executed. The reign of Edward III. is looked upon as one of the most brilliant in English history. He was an energetic prince, and repressed the lawless men who had had their way during his father's reign. Aiding Baliol in an attempt to obtain the crown of Scotland, he won over the Scotch the victory of Halidon Hill, but the defeated were not conquered. He set up an absurd claim to the crown of France, in right of his

mother, which led to that rivalry of France and England that has endured down to this day. He had numerous allies on the continent, and he led an army into France in 1338, which, however, accomplished nothing. The great naval victory of Sluys was gained by the English in 1340. Troubles with parliament and want of money prevented him from urging the war vigorously, and it was not until 1346 that the battle of Crécy was won by the English. Calais was afterward taken, and the king then made a truce with the French. While he was absent, an army raised by his wife defeated the Scotch at the battle of Neville's Cross, and captured their king, David Bruce. A naval war with the Spaniards followed, and the latter were defeated in a great battle. The terrible pestilence that ravaged the world in the 14th century appeared in England in 1349. The renewal of the war with France led to the battle of Poitiers in 1356, in which Edward, prince of Wales, known as the Black Prince, defeated King John of France, and made him prisoner. In 1359 Edward III. again invaded France, and besieged Rheims, because he wished to be crowned king there. The next year peace was made between the two countries, Edward renouncing all claim to the French crown, but receiving large portions of French territory, and an immense sum of money. The French king, finding himself unable to fulfil the terms of the treaty, went back to England a prisoner, and there died. The prince of Wales, from Guienne, interfered in the affairs of Spain, and won the battle of Najera in 1367, in behalf of Peter the Cruel, and over the French, who, under Du Guesclin, were aiding Henry of Trastámara. The expense of this war caused the prince to become unpopular, and his last days formed a miserable contrast with his early career. He died in 1376, a year before the death of his father. The latter years of the king were also embittered by failure in France, and by disputes with parliament. Not a little was done in this reign toward the development of English industry, and some constitutional questions were settled. The new king, Richard II., son of the Black Prince, was only 11 years old, and a regency was appointed. The war with France languished. The peasantry, headed by Wat Tyler, rose in rebellion, the movement being in principle like the *Jacquerie* that had occurred in France immediately after the battle of Poitiers. The young king showed both tact and courage on this occasion, and gave promise of greater ability than was justified by his career. A war with Scotland led to no results. The ambition of the king's uncle, the duke of Gloucester, caused internal troubles. The king wasted on frivolous pleasures money that had been granted him for other purposes, and he completed his unpopularity by making a long truce with France, and by marrying the daughter of Charles VI., a child of 7 years. His uncle Gloucester sought to avail himself of this unpopularity, but was seized, imprisoned, and put to death, while his

party was destroyed. Parliament stood firmly by the king. Two of his supporters were the duke of Hereford and the duke of Norfolk, and they quarrelling, the king banished them both, the first for 10 years, and the second for life. Hereford was son of John of Gaunt, the duke of Lancaster, and cousin of the king, and when, on his father's death, the king seized his cousin's estates, the new duke of Lancaster returned to England, and, so great was the monarch's unpopularity, rapidly levied a force that placed him at the head of the country. He compelled the king to resign the crown, and assembled a parliament, which made him king, he having claimed the throne in virtue of his descent from Henry III. According to the received ideas of succession, he had no claim to the throne, which, failing Richard and heirs of his body, belonged to the earl of March, descended from the duke of Clarence, 3d son of Edward III., the new king being son of Edward's 4th son. The reign of Henry IV. began Sept. 30, 1399. Richard was imprisoned, and is supposed to have been murdered at Pontefract castle, but nothing is certainly known of his fate. Henry's reign was one of much interest. The followers of Wycliffe had become very numerous, and the king's father, John of Gaunt, duke of Lancaster, had supported Wycliffe; but the son proved a firm adherent of the church of Rome, and consented to that act for the punishment of heretics which was passed in 1401, and under which so much cruelty was perpetrated for two centuries. The Lancastrian dynasty, by allying itself with the church, postponed the reformation for 4 generations. The reign of Henry IV. was short, but eventful. In a war with Scotland the English won the victory of Homildon Hill. The rebellion of Glendower, in Wales, was highly successful for many years, and that chief was never formally subdued, though finally forced to remain in a state of comparative quiet. A rebellion headed by the earl of Northumberland broke out in 1403, but the victory of the king at Shrewsbury established his power. Other rebellions followed this, and the conspiracies were numerous. The French had insulted the English frequently, and Henry IV. was on the point of renewing the war, when illness compelled him to refrain; and soon after he died, March 20, 1413. His son and successor, Henry V., put down the Lollards with a vigorous hand, and renewed the war with France. Landing in France with a large army, in the summer of 1415, he besieged and took Harfleur. The battle of Agincourt was fought Oct. 25, 1415, and was won by the English against great odds, the French suffering severely. The war was continued, and in 1420 the French government made a treaty with England, by which it was settled that Henry V. should marry Catharine, one of the daughters of Charles VI., and that he should become heir to that king. On Charles's death France and England were to have but one monarch. Fortunately for England—which by its success would have been probably reduced to

the condition of a province of France—this plan was destined to fail. Henry died, Aug. 31, 1422, when apparently about to realize his scheme. He left but one child, a boy of 9 months, who became Henry VI., and who was soon the king of a large part of France, his French grandfather dying soon after his father. The king's uncle, the duke of Bedford, carried on the war, and the English were mostly victorious over the French and their Scotch allies. A variety of events, however, among which the exploits of Joan of Arc are the most remarkable, led to a change in the fortunes of the contest, and after many campaigns the French recovered all their country, except Calais, and two other small places, in 1451. Henry VI. proved to be a man of much amiability, but deficient in intellect and vigor of character. During his minority the court was the scene of intrigues and contentions; and when he had arrived at manhood, and married Margaret of Anjou, daughter of René, titular king of Sicily, Naples, and Jerusalem, that able princess became the real head of the state. The conflicts of parties were increased in fierceness, which was in part caused by the throwing of so many public men back upon England, who had lost all they had seized in France. That contest which is known as the wars of the roses, or the disputes of the houses of York and Lancaster for the crown of England, commenced about 1452. Richard duke of York was undoubtedly the legitimate claimant of the throne. Had Henry VI. been an able monarch, the claims of York under the circumstances would have been of little practical importance; but the weakness of the king, and the fierceness of the party contests, united to concentrate men's attention upon the duke, who had many strong points of character, and had served his country well in France and Ireland. He had married Cecily Neville, daughter of the earl of Westmoreland, a near connection of the earls of Salisbury and Warwick, two of the greatest nobles of the realm. The duke expected to succeed quietly to the crown on the king's death, as Henry had no children for many years after his marriage; but in 1453 Prince Edward was born, and the king was reduced by illness to a state of imbecility. York was then made protector; but when Henry, in 1455, recovered his intellect, he resumed power, and showed such favor to the duke's enemies that the Yorkists assumed arms, and that civil war began which did not end until 40 years later. The first battle was fought at St. Albans, May 22, 1455, and was won by the Yorkists, or party of the white rose. The king was in the power of the conquerors, and acceded to all the demands of York, who became protector again on the return of Henry's illness. The queen was less submissive, and nearly succeeded in her attempts to destroy the opposition chiefs. War was resumed in 1459, with various fortune. After the battle of Northampton, July 10, 1460, it was arranged that Henry should remain king for life, but that York should succeed him. Margaret re-

sisted, and on Dec. 30, 1460, defeated the Yorkists at Wakefield. York and his young son, the earl of Rutland, and his chief supporter, Salisbury, were put to death. The Yorkist claim now passed to Edward, earl of March, the duke's eldest son, a youth of 19, superior to his father in intellectual qualities, but his inferior in virtue and humanity. Edward, who had great military genius, marched against one of the Lancastrian armies, and defeated it, and then proceeded to London, where the people and some of the parliament acknowledged his claims. He was proclaimed king, March 5, 1461; and so prompt were his movements that he met the Lancastrian army at Towton, a few miles from York, the 29th of the same month (Palm Sunday). A hundred thousand men joined battle, and after the most terrible conflict that ever occurred on English ground, victory declared for Edward IV. Margaret renewed the contest with French and Scottish aid, but was beaten at Hexham, May 15, 1464. Henry fell into his rival's hands, and was imprisoned in the tower. The power of the Yorkists being established, they fell to quarrelling among themselves. The Nevilles, at whose head stood the earl of Warwick, claimed more than the king was disposed to grant, even for such services as they had rendered, and which, being too important to be rewarded, naturally made them and the royal house enemies. The king's marriage with Lady Grey, widow of an obscure Lancastrian, gave much offence to Warwick and his friends. The duke of Clarence, a brother of the king, married the eldest daughter of Warwick, to the disgust of the monarch. In 1469 there was a rebellion, headed by the Nevilles, who were aided by Clarence, and the king at one time was their prisoner. Released from confinement, Edward put down another rebellion, and conferred high favors on Clarence and Warwick; but the quarrel was renewed, and failing to seize the king, the rebel chiefs fled to France, where Warwick, under the mediation of Louis XI., joined the party of Margaret of Anjou. Landing in England, and proclaiming Henry VI. king, Warwick was everywhere successful, and Edward fled to Holland. In a few months Edward returned, and was as successful as Warwick had been. In 4 weeks he entered London, having been joined by his brother Clarence. The battle of Barnet was fought April 14, 1471, and the Lancastrians were defeated, Warwick and his brother Montague falling on the field. On May 4, Edward again defeated the Lancastrians at Tewkesbury, Prince Edward, son of Henry VI., falling in the action. Margaret of Anjou was made prisoner, and sent to the tower, where her husband was put to death, May 21. Edward was no more disturbed by the Lancastrians, but the dissensions at his court between different branches of the Yorkist party, and between himself and his brother Clarence, caused him great trouble. Clarence he put to death. He invaded France at the head of a large force, but Louis XI. bought peace of him, and he returned to England. He

died in 1483, worn out by debauchery. His successor, Edward V., was not quite 13 years old. The court was divided into two parties, the one consisting of the relatives of the young king on the maternal side, and the other of the old nobility. Richard, duke of Gloucester, the king's uncle, an able and ambitious prince, seized the reins of government, was made protector, put to death several of the monarch's relatives and supporters, and finally made himself king. Edward V. and his brother, the duke of York, were placed in confinement, and soon disappeared, but it is not certain that the common story as to their fate, that they were murdered by Richard's orders, is true. Richard's reign was brief, and was much disturbed by conspiracies; he had offended the Yorkists, and had not conciliated the Lancastrians. A coalition was formed against him, at the head of which stood the earl of Richmond, the last person who could pretend to be the representative of the house of Lancaster. Richmond was the great-great-grandson of John of Gaunt, founder of the house of Lancaster, being descended from the earl of Somerset, son of that prince by Catharine Swynford, his mistress. Somerset had been legitimated by parliament, but cut off from the line of succession to the crown. On his father's side Richmond belonged to the Welsh family of Tudor, his grandfather, Owen Tudor, having married Catharine of Valois, widow of Henry V. of England. Thus Richmond had no legitimate claim to the throne; and even if Richard III. were dead there were several persons who had superior claims to that seat in point of blood, supposing that the limitation of the rights of Richmond's grandfather Somerset was not regarded. But party exigencies overcame every thing, and to satisfy the Yorkists it was agreed that Richmond should marry Elizabeth, eldest daughter of Edward IV. The first effort of the conspirators failed, and the duke of Buckingham, the chief of them in England, was beheaded. In 1485 they were more successful. Richmond landed in Wales at the head of a small force, marched into England, encountered Richard at Bosworth, Aug. 22, and defeated him, the king falling in the battle. Richard would have won an easy victory had it not been for the treachery of some of his adherents. The crown that he wore in the action was placed on the head of Richmond, who was hailed as Henry VII. This monarch, first of the Tudor line, bore himself as chief of the Lancastrian party, and depressed the Yorkists whenever he could do so, though he felt himself compelled to marry the princess Elizabeth. His reign was disturbed by many conspiracies, and by the appearance of pretenders to the crown. The first of these pretenders was one Lambert Simnel, who personated the earl of Warwick, son of the last duke of Clarence, and undoubted heir to the crown failing children of Edward IV. The Irish supported this pretender, who was the son of an English baker, and he was aided by the duchess

dowager of Burgundy, a sister of Edward IV., and notorious for her hatred of Henry VII. At the head of the miscellaneous force which was collected, Irish and foreign soldiers, the Yorkist leaders landed in England, and had they received any considerable English support, they would probably have succeeded; but they were left to fight unaided, and were totally defeated at Stoke, June 16, 1487. Among the slain was the earl of Lincoln, next to Warwick the chief member of the house of York. Simnel was taken prisoner and made a scullion in the king's kitchen. Another pretender is known to history as Perkin Warbeck, said to have been the son of a Tournay trader, but who claimed to be Richard Plantagenet, duke of York, 2d son of Edward IV., a claim which has found strong defenders. Henry regarded him as a much more important character than Simnel, and foreign potentates treated him as if they believed in his claim. James III. of Scotland gave him one of his relatives in marriage, and marched an army into England to aid him. But all his efforts proved failures. A Cornish insurrection was put down vigorously by the king, at the battle of Blackheath; yet when the pretender entered Cornwall he was regarded as king, was joined by a large force, and laid siege to Exeter. On the approach of the royal army, however, he fled, and subsequently surrendered on condition that his life should be spared. Flying a second time, he again gave himself up on the same terms, but was set in the stocks, and made to read a confession that he was an impostor. Consigned to the tower, he sought to escape, and was hanged at Tyburn (1499). Henry at the same time caused the earl of Warwick, the last survivor of the legitimate male descendants of Edward III., to be put to death, on a groundless charge of conspiracy with Perkin. With these proceedings may be said to have closed the contest between the houses of York and Lancaster, in the complete prostration of the former, though the latter was represented by a bastard member who was not even descended from Henry IV., the founder of Lancastrian royalty. The last years of Henry VII. were more peaceably passed, and he became a powerful sovereign at home, while his influence was great abroad. His master passion was avarice, and he hesitated at no means to gratify it. He pretended to make war on France, but only that he might obtain money from his subjects, and then sold peace to the French monarch. He depressed the power of the high nobility in various ways. The law that no man should be held guilty of treason for adhering to the king *de facto* was passed in his reign. He died April 21, 1509. Henry VIII., his successor, was his second son, the first, Arthur, having died before his father. Arthur had married Catharine of Aragon, one of the daughters of Ferdinand and Isabella, and on his death his father had procured a dispensation from the pope allowing the marriage of Catharine and his second son. This marriage was not solemnized until after

the accession of Henry VIII., whose father seems to have had some scruples on the subject. The reign of the new king was destined to be the most momentous in the annals of England. He was frequently engaged in hostilities with foreign countries, and the great victory of Flodden was won by one of his generals over James IV. of Scotland, husband of his sister Margaret. His policy was the result of his passions. That he was troubled concerning his marriage with his brother's widow, after that marriage failed to produce sons that could arrive at maturity, is easily believed, as he was singularly superstitious; but it required his passion for Anne Boleyn to give his scruples much force. Had the court of Rome aided him to a divorce, he would have remained a Catholic; but that court refusing to declare void a marriage which the church had sanctioned, he threw off his allegiance to the pope, and became head of the church in England. He was 6 times married, and 2 of his wives were beheaded and 2 were repudiated. It has been alleged that much that was severe in Henry's treatment of his wives was owing to his desire to have heirs, the wars of the roses in the preceding century having made English sovereigns, statesmen, and people very sensitive on the subject of the succession to the crown. Henry interfered much in continental politics, and the European balance of power theory dates from his time. In his reign the scaffold was constantly occupied by victims from every class of society, the number of whom, however, has been considerably exaggerated. The highest classes were probably the greatest sufferers; the king was impartial in the selection of his victims, and usually as unjust as he was cruel. He died Jan. 28, 1547, and was succeeded by his only son, Edward VI., whose mother was Jane Seymour, Henry's 3d wife. Edward was in his 10th year, and the government was placed in the hands of a council of regency, the principal members of which were the earl of Hertford, the king's uncle, soon created duke of Somerset and protector, and Archbishop Cranmer. In this reign the church of England was established, and the nation placed on the Protestant side in the struggle then going on in Europe. In the contests for power that took place at court, Somerset was finally worsted, and then beheaded. Dudley, duke of Northumberland, into whose hands all power passed, caused his 4th son, Lord Guildford Dudley, to marry Lady Jane Grey, great-granddaughter of Henry VII.; and when Edward VI. died, July 6, 1553, the duke made the lady Jane queen, to whom Edward had been persuaded to bequeath the crown. Her reign lasted but 10 days, and her party was quickly dispersed. Mary, eldest daughter of Henry VIII., ascended the throne, and behaved mercifully toward most of those who had sought to prevent her succession. Northumberland and others were executed, but the lady Jane and her husband were spared until the next year, when they were executed, in consequence of the lady's father, the duke of Suf-

folk, having taken part in Wyatt's rebellion. Suffolk also was executed. Mary effected a reconciliation with Rome, and gave her hand to Philip II. of Spain. This marriage led to war between England and France, and an English army joined the Spanish force that invaded France, and took part in the battle of St. Quentin. The French succeeded in an attack on Calais, the loss of which shortened Mary's life. She was a devout Catholic, and caused Cranmer, Latimer, Ridley, and about 300 other Protestants, to be burned. Her death, which occurred Nov. 17, 1558, left the throne to Elizabeth, who felt herself compelled to side with the Protestants. Her reign, which lasted more than 44 years, is one of the most brilliant in English history. Sagacious in the selection of her counsellors, she was able to triumph over all her enemies, and to raise her kingdom to the first place in Europe. She ruled over Scotland in fact, and put the sovereign of that country to death after having held her in unjust captivity nearly 19 years. The Huguenots of France and Henry IV. received aid from her, and but for the assistance she gave the Dutch they would have sunk under the power of Spain. She invited the Turks to join her in attacking the pope and the king of Spain; and over both those potentates she achieved a great triumph in 1588, when the armada was destroyed. Both Catholics and Puritans were persecuted by her government. The English mind was then singularly fertile, and some of the greatest names in the literature of England belong to the Elizabethan age. The enterprise of Englishmen led them to circumnavigate the globe, to attempt colonization, to extend trade, and to commence that intercourse with India which was destined to lead to extraordinary results. Elizabeth had not much to do directly with these things; but she was the sovereign of the country, the central figure of a great nation in a great age, and all that was accomplished by her subjects was allowed to increase the splendor of her glory. She died March 24, 1603, and with her terminated the Tudor dynasty, after an existence of nearly 118 years. She was succeeded by James VI. of Scotland, first king of England of the Stuart line, who inherited the English crown in virtue of his descent from Margaret Tudor, eldest daughter of Henry VII., who had married his great-grandfather, James IV. The new king was hailed with much satisfaction by the English. The natural fondness of men for change had something to do with this, but it is but just to say that the question of the succession to the throne had been one of vital interest to the English from the time of the wars of the roses, and particularly since the successive wives of Henry VIII. had proved so unfruitful. Rulers and people alike had been deeply moved by the constantly impending danger of a disputed succession, and from the death of Edward VI. to that of Elizabeth, only two women of the main line were in existence, and for 44 years only one woman, Elizabeth herself. The anxiety that was felt for the marriage of Elizabeth was owing to this dread that

haunted the minds of her subjects of all classes; so that when the sceptre passed quietly to the hand of a monarch who was descended from their ancient kings, who was not yet at the period of middle life, and who was the father of several children, a weight was taken from the English mind that had long oppressed it, and demonstrations of joy were common that by no means implied weariness of the Elizabethan rule. Had James been a man of ordinary capacity and common sense, he might have preserved this popularity, and laid deep the foundations of his dynasty, but he was a pedant, and a tyrant, without the courage which is necessary to maintain a tyranny. His person, his manners, and his actions were all against him; and before he had reached London his popularity began to decline, and was quickly exhausted. He commenced that course of policy which was destined to cause his house to become extinct in exile. The divine right of kings, so abhorrent to reason and to English ideas of government, was the basis of his conduct, and was made contemptible by his mode of proceeding. He perpetually claimed higher power than any Plantagenet or Tudor had claimed, but he invariably abandoned his ground when he was resisted. It has been sought to defend his course by stating that he was ignorant of the constitution and laws of England, and sinned without knowledge; but this excuse, which would be of little moment under any circumstances, is of none whatever in his case. His very first parliament, 1604, in reply to his first assertion that all their privileges were derived from him, asserted in full, and in the plainest language, all those principles for which the English constitutionalists contended against 3 generations of Stuarts, and asserted them as facts not to be questioned. Then began that civil contest which lasted down to 1689 in full force, and which was not utterly at an end until 1746. The foreign policy of James was as vicious as his home policy, and England became of less account in the European world than a second-rate German or Italian principality. Shortly after his accession, Beaumont, the French ambassador, prophesied that for a century England would hardly misuse her prosperity to any other purpose than her own injury, a prediction that came marvellously near to literal fulfilment. This was well, for if the Stuarts had known how to be popular kings the English constitution would have been destroyed; but, though generally men of ability, they seem to have delighted as much in annoying and degrading their subjects as in directly misruling them. James I. died in 1625, and was succeeded by his son Charles I., a monarch who had some elegant, gentlemanlike tastes, but who apparently could not conceive of any obligations on the part of a king to his subjects. He did not put forward his pretensions so offensively as similar ones had been put forward by his father, but he adhered to them with a courage and a tenacity that were utterly unknown to James. He set deliberately

to work to introduce into England the system of government that prevailed in France, to do in England and Scotland what the Austro-Burgundian princes had done in Castile and Aragon. Even the wretched excuse of ignorance that has been pleaded for James cannot be used in behalf of Charles; for he had been educated in England from his early childhood, had good faculties, and had by his assent to the petition of right—an instrument, all its circumstances considered, even more important than Magna Charta—expressly agreed not to rule arbitrarily for a full and solid consideration paid into his hands. For 11 years (1629–'40) he called no parliament, and England was as despotically ruled as France; and had all his instruments been prudent and able men, it is possible he would have succeeded in his design. His chief instruments were Wentworth, afterward earl of Strafford, and Laud, archbishop of Canterbury; the former one of the ablest of men in an age singularly prolific in able men; the latter equally distinguished for his narrowness of mind. These two men, it should seem, were associated only that the wisdom of the one might be confounded by the folly of the other. Laud gave precedence to ecclesiastical tyranny, whereas Wentworth, if he had had entire management of affairs, would have established political despotism, whence religious uniformity would have soon followed. It is very doubtful whether the people could have been stirred up to the fighting point if their religious sentiments had remained without serious disturbance until their political rights had been totally subverted. The bigotry of Laud caused him to seek to fasten the English church polity on Scotland, which was met by that deep and determined resistance on the part of the Scotch which is so striking a trait in their character when their principles or prejudices are assailed. War between the Scotch people and the English government followed, and Charles was compelled to call a parliament, April, 1640. Thus were all Wentworth's sagacious plans set at naught. The parliament, known in history as the short parliament, lasted but a few days, when it was dissolved, in the mere wantonness of tyranny. Six months later assembled the famous long parliament, which the king's necessity forced him to call. The parliament punished the king's tools, and forced him to admit that it should not be dissolved without its own consent. It then proceeded to divest the king of much of his power, demanding, among other things, control of the militia. It may be admitted, without any reflection on the memories of Pym and Hampden, and their associates, that the parliament party went beyond the limits of the constitution, in their desire to preserve the constitution. Their excuse is to be found in the purpose and acts of the king, and in his incurable falsehood. Yet they did not go so far as the men of 1688–'9 went, who set aside a dynasty in order to place the constitution beyond danger. It matters not that Charles was beheaded in 1649; we know that the political leaders of 1640–'42

never counted upon the king's death or deposition, and that at no time was it out of his power to have reigned in strength and peace, on the sole condition that he should rule as a constitutional sovereign. Had they set aside the dynasty, there would have been no occasion to change the constitutional practice; but that was impossible. It was natural that Charles should refuse to part with power that was legally his; and it was equally natural that the parliament should refuse to allow it to remain in his hands. Both parties appealed to arms, and what is known as the great civil war began in the latter part of 1642. At first fortune favored the king, whose wrong-headedness however rendered him unable to profit therefrom. Gradually the radical party in parliament gained strength, and, under the lead of Vane, Cromwell, and others, rose to power. Cromwell was everywhere victorious in the field. Parliament was "purged" of all who showed any disposition to treat with the king. The army became the source of all power. The king was tried, condemned, and executed. Ireland was conquered by Cromwell, who was almost equally successful in Scotland. The battle of Worcester, Sept. 3, 1651, crushed the royalists for nearly 9 years. In 1653 Cromwell dissolved the parliament by force, and was master of England for 5 years, ruling the country far more wisely than ever it had been ruled by a Stuart, but still with an iron hand, which he did not condescend to cover with a velvet glove. He would have ruled constitutionally if he could, but by him the English would not be so ruled. He wished to become king, but this the army would not allow, for it was composed of men who were sincere republicans, and who acted conscientiously. Yet England then occupied the highest place she had ever known in the world's estimation; one in striking contrast to that which she had held during the 40 years of the rule of James I. and Charles I. After Cromwell's death, in 1658, dissensions broke out among the military, and the military and civil republicans quarrelled. Richard, the inferior son of the great protector, resigned, and thus was prepared the way for the restoration of the Stuarts, effected by Gen. Monk, in 1660. The reign of Charles II. dates from that year, May 29, in fact, though in law it dates from the day of his father's decapitation. The change was prodigious. The austere Puritans were succeeded by profligate cavaliers; but for this the former were most to blame. They had insisted upon ruling the nation into righteousness, and had caused that reaction which ended in the foulest licentiousness. It has been truly said that the reign of the saints produced the reign of the harlots. Many of the reforms effected by the long parliament were preserved. That body had swept away the court of star chamber, the high commission court, and the council of the north, all tremendous instruments of royal tyranny, and not one of these was it possible to revive. Other good effects of the legislation of that great parliament were preserved.

The nation had gone forward, and it was not possible for it to go backward, even under the effect of that singular reaction which caused usually sensible men to welcome back the profligate king with tears in their eyes. Had Charles II. been an ambitious monarch, he might have accomplished what his grandfather, his father, and his brother were unable to accomplish; he might have established despotism in England, at least for a time. But, though one of the ablest members of his family, he was singularly destitute of those feelings which ordinarily are found in monarchs. He loved his ease above all things, and if he could get pleasantly through the 24 hours he was quite willing that other men should do so. He had many of those qualities which are popularly attributed to his grandfather, Henry IV. of France; but he probably laughed at his ancestor's daring in the field. His vices were of the popular kind, and such as even moral men are ready to forgive in kings. From the 11th to the 30th year of his age his life had been passed amid civil disputes, wars, wanderings, and intrigues, and in poverty; and he had contracted from this experience a horror of every thing that looked like danger, or that was business. Happen what might, he is reported to have said, he would not again go on his travels. From the personal selfishness of this easy voluptuary England derived almost as much good as from the tyranny of John or the cowardice of James I. He was content to rule as much through parliament as could be expected from a monarch under no more restraint than he was. Several times, when more daring natures than his own had caused him to venture upon some despotic act, he was ready to give way when he found the opposition resolute. He retreated from the ground assumed in his declaration of indulgence, and so weakened the royal power. His popularity soon underwent a decline, which was principally attributable to the meanness of his foreign policy. With the restoration of the Stuarts was also restored that policy in foreign affairs which had reduced England to so low a state in their first two reigns. England's honor, it may be said, was gibbeted with Cromwell's body at Tyburn. An unnecessary war with the Dutch produced much disgrace. The triple alliance which was entered into with Sweden and Holland, and which for a brief interval stayed the course of Louis XIV., was the solitary act of the kind that reflects honor on this reign. The king, however, soon became the tool and pensioner of France. His forces assisted in the war on Holland made by Louis XIV. The unpopularity of this course, and the internal misgovernment of the cabal ministry, created a great change in English opinion, and finally assistance was sent to the Dutch. The peace of 1678 was followed by the excitement caused by the alleged popish plot, and for a time the king was almost as unpopular as his father had been in 1640. Parliament after parliament was elected, met, set itself in decided opposition to the government, and was dissolv-

ed. The leading object of the opposition was the exclusion of the duke of York from the line of succession; and even to this the king would finally have consented rather than have fought. But the reaction that set in saved him from the last disgrace. When the Oxford parliament was dissolved, in 1681, the king found himself hardly less powerful than he had been in 1660. He never called another parliament, but was able to govern without one. The conspiracies that were formed by the whigs (the names of whig and tory had their definite political commencement in 1680) were detected, and many of the conspirators were punished. Others, men of whom the government wished to be rid, such as Russell and Sidney, were judicially murdered. Few kings have been more powerful than Charles II. was during the last 3 years of his reign, yet some marked advantages had been obtained by the constitutionalists, which have endured. The *habeas corpus* act of 1679 was among the greatest triumphs of the liberal party, not only in itself, but because it furnished a point of union between whigs and tories; for in the next reign it was found that the tories, even when most servilely loyal, could not be prevailed upon to repeal that act. Charles II. died suddenly in Feb. 1685. James II. came to the throne without the slightest opposition, and for a brief period was popular. Though an open and avowed Catholic, he was beloved fanatically by the priesthood of the church of England, which indeed had saved his inheritance in the days of the exclusion bill. Had he been content with persecuting dissenters and whigs, and with destroying much of the civil liberty of his subjects, it is not unlikely that he would have made himself as powerful as Henry VIII. had been; but he wished to reëstablish the ascendancy of his own church, which could not be done without overthrowing the Anglican church, and spoiling the aristocracy of much of their property, and thus he united church, aristocracy, and all the intelligent part of the people against him. The parliament he summoned was so servile that it is impossible to class it with those noble bodies which had done so much to vindicate the liberties of England. Even the parliament of 1660 seemed manly and liberal in comparison with it. Yet this servile body could not satisfy the king, and he broke with it on points that plainly showed he was bent on the establishment of a despotism, and the destruction of the constitution in church and state. Before this happened, he had put down the attempt of Monmouth to subvert the government, punishing the chief and his followers with a vindictiveness to which there are few parallels in history. So complete was the terror caused by these punishments, that not even the union of churchmen, dissenters, the aristocracy, the legal profession, and the middle classes of almost every faith, could have availed to effect his overthrow, had not that union been supported by a large foreign army, headed by a prince of the highest reputation as a soldier and a statesman. The king prorogued parliament in Nov.

1685, and that body never met again. For 3 years he governed despotically, and there was a contest perpetually waged between him and his people; and the vigor with which the contest was fought on the popular side shows how well established was the English constitution. The king at first sought the aid of the church against the dissenters, and received it until the church found he meant its own destruction, together with that of all other forms of Protestantism, when it revolted, in spite of its passive obedience doctrines. He then sought an alliance with the dissenters against the church, and though some of them, as was but natural, were ready to aid him, the great majority of their number remained true to the constitution. By the autumn of 1688, the king was opposed by almost all classes of his subjects, and could not procure the services of even third-rate lawyers in an age proverbial for the baseness of its legal men. William, prince of Orange, had watched the contest in England closely. He was the king's nephew, son of his sister Mary, and had married the king's eldest daughter Mary, heir apparent to the British crown. It is not probable that he cared much for the liberties of England, for he was the chief of that party in Holland which was opposed to the existing constitution, a polity in its spirit not unlike to that of England; but he was firmly opposed to Louis XIV., and desired to have the aid of England in thwarting his schemes; and James was the pensioner and ally of Louis, and so would remain so long as he should persist in governing England illegally. While Mary of Orange stood next in succession to James, her husband could not do much in opposition to that king; but he let it be known that his sympathies and those of his wife were with the constitutionalists. James had married for his second wife Mary Beatrice, a princess of the house of Este of Modena, and from this union had proceeded 4 children, all of whom had died. It seems to have been taken for granted that this couple were to have no more children, and that in due course James would be succeeded by his daughter Mary; but in 1687 the queen was declared to be pregnant, and on June 10, 1688, was born that prince who was afterward known as the pretender. This incident precipitated matters, for the opinion was almost universal in England that a supposititious child had been placed in the position of heir apparent to the crown. June 30, 1688, William was invited to invade England at the head of an army. This invitation was signed by the earls of Shrewsbury, Devonshire, and Danby, by Lord Lumley, by Henry Sidney and Admiral Russell, and by Compton, bishop of London; and it was accepted. A variety of circumstances favored the undertaking, and on Nov. 5 William landed at Torbay, at the head of a well-appointed army, 15,000 strong, composed of men of several nations. At first the people were slow to join him, and after having advanced as far as Exeter, he talked of returning to his ships; but men of note now began to repair to his standard, and it

was found that James had no hold even on the great army which he had established in defiance of law. He was deserted by those upon whom he ought to have been able to rely, even his daughter Anne joining his enemies. He gave way to terror, hastened to undo all he had done, and fled. Brought back to London, he fled a second time, and reached France, where he had previously sent his wife and son. All England was in the hands of William and his friends. The convention parliament that assembled, after much discussion, conferred the crown on William and Mary, which was a revolutionary act, as not only were James and his son alive, but Mary and Anne had claims to the crown compared with which those of William could not bear criticism. The declaration of right placed the ground of action on the vindication of the "undoubted inheritance of Englishmen," the entire movement being conservative in its character, and not one of innovation. The events of 1688-'9 are known as the English revolution, but it would be more correct to call them the close of that revolution; for the contest that had commenced with the coming of the Stuarts to the throne, and which had lasted for 86 years, was virtually closed on the day that William and Mary were proclaimed king and queen of England. For 170 years the government of England has been constitutional without question, a circumstance totally without parallel in the history of great nations. If we except the rebellions of 1715 and 1745, that country has been the scene of no serious outbreak against established authority for 5 generations. Faults there have been in both government and people, but not greater than are to be found in the corresponding annals of other European nations; while in no other country of the old world has the good that England has known had an existence. Liberty and law have gone hand in hand together, each sustaining the other, mutually imparting a portion of their spirit. Moral, intellectual, and material progress through 5 generations has made England the first of nations, and left her, in some important respects, without a rival. The greatness of England, her moral power, in no small degree her literature, and the fact that she is the mother of nations destined perhaps to excel herself, are all due to the happy settlement that was effected in 1688-'9, which was the completion, by one set of patriots, of what other patriots had initiated or forwarded. Macaulay, writing at the time when all continental Europe was agitated by the revolutionary convulsions of 1848, claimed, with the natural and just pride of an English statesman, that England's exemption from those convulsions was due to the wisdom of her leading men of the 17th century. "In our island," he says, "the regular course of government has never been for a day interrupted. The few bad men who longed for license and plunder have not had the courage to confront for one moment the strength of a loyal nation, rallied in firm array round a parental throne. And if it be asked

what has made us to differ from others, the answer is that we never lost what others are wildly and blindly seeking to regain. It is because we had a preserving revolution in the 17th century that we have not had a destroying revolution in the 19th. It is because we had freedom in the midst of servitude that we have order in the midst of anarchy. For the authority of law, for the security of property, for the peace of our streets, for the happiness of our homes, our gratitude is due, under Him who raises and pulls down nations at his pleasure, to the long parliament, to the convention, and to William of Orange." William III. found his new throne any thing but an agreeable seat, but possession of it enabled him to combat Louis XIV. with ultimate success, though the war that England declared against France, in 1689, was marked by many reverses on the part of the former. It was terminated by the peace of Ryswick in 1697. Ireland was subdued almost as completely as she had been subdued by Cromwell more than 40 years earlier. There were several conspiracies formed against the new government, but they all failed, and many of the conspirators were punished. The bank of England was established in 1694. Mary died in 1694, and left William sole monarch. The freedom of the English press dates from 1695. Most of the legislation of this reign was of a liberal character, and would have been far more so if William's wishes could in all cases have prevailed. Much of the evil of those times grew out of differences in religious belief, and William was singularly free from bigotry, though few men have been more devout than he was. The toleration act, which has been pronounced by the highest authority as "that which most strikingly illustrates the peculiar vices and the peculiar excellences of English legislation of all the acts that have ever been passed by parliament," was adopted in 1689. The last years of William's reign saw him enter into two partition treaties with Louis XIV. to dispose of the immense dominions of the Spanish branch of the house of Austria, Charles II. being without heirs of his body. Louis violated the second treaty in 1700, and William would have made war on him, but circumstances prevented him; and there was every prospect that the entire Spanish monarchy would pass to Philip of Anjou without a serious struggle, when Louis threw the whole British nation into a rage by acknowledging the son of the exiled James II. king of Great Britain, James dying in 1701. William took advantage of this blunder, and was preparing for vigorous war when he died, March 8, 1702. The year before his death he had the satisfaction of seeing the finishing stroke put to the work of that revolution with the close of which his fame is indissolubly associated. In 1613 Elizabeth Stuart, daughter of James I., had wedded the elector palatine, Frederic V., who afterward became king of Bohemia, but who could neither keep his new kingdom nor preserve his old palatinate. The

youngest child of this marriage was a daughter, Sophia, married to Ernest Augustus, first elector of Hanover. As early as 1689, William had been desirous of entailing the British crown on this lady, and the house of lords unanimously agreed to an amendment of the bill of rights to that effect. The commons unanimously rejected the amendment. While the two houses were conferring on the subject, a son, afterward known as duke of Gloucester, was born to the princess Anne. Neither house would give way, and the bill of rights was lost. The duke of Gloucester died in 1700, and in 1701 William's old plan was adopted. The crown was entailed on the electress Sophia. An act more revolutionary in its character was never passed by a legislative body. All the descendants of James II. and Charles I. were passed over, and the preference given to a granddaughter of James I., for the sole reason that she was a Protestant. There were then living 57 persons who had claims to the crown superior to those of the electress, according to the received ideas of the right of succession. William was succeeded by the sister of his wife, Anne, second daughter of James II. May 15, 1702, war was declared against France, that war which was illustrated by the deeds of Peterborough and Marlborough, and which lasted 11 years, when it was concluded by the treaty of Utrecht, in which the English are thought to have thrown away nearly all the fruits of their many victories. The war party had gone out of office, in consequence of the hostility of the church, and their successors were supposed to aim at the restoration of the Stuarts, though, at the most, this suspicion of Jacobitism could apply only to Bolingbroke. The union of England and Scotland was effected in 1707, the latter country being allowed to send 45 members to the house of commons, and 16 to the house of peers. Anne died Aug. 1, 1714, and the crown passed without a struggle to the house of Hanover. The reign of George I. was by no means a brilliant one. The rebellion of 1715, in behalf of the Stuarts, proved a failure, and the foreign movements for the same object were quite as useless. England allied herself with France, then ruled by the regent Orleans. The whigs returned to power, which they kept until the reign of George III. The South sea bubble caused great distress. Walpole's ascendancy began with its explosion, though he had been in office long before that date. England was involved in war with Spain, and in 1718 won the naval victory of Cape Passaro. George I. died in 1727, and was succeeded by his only son George II., between whom and himself there had been bitter hatred. The new king, under the influence of his wife, Caroline of Anspach, continued Walpole in office, and that great minister was at the head of affairs until the beginning of 1742, baffling for years all the exertions of the most able and unscrupulous opposition that has ever existed in a free state. His principle of action was "to let well alone;" but as he thought things were well which it would have

been better to improve, he failed in his duty to his country. He allowed himself to be forced into a war with Spain, which departure from his system was soon followed by his fall, though he retained his influence over the royal mind to the day of his death. His successors were whigs in principle, and there was no chance for the tories, as a party, under the first two monarchs of the Hanoverian line. War with France was added to that with Spain, growing out of the question of the Austrian succession. As a whole this war was one of the least glorious ever waged by England. In 1745-'6 the contest between the reigning dynasty and the remains of the Stuart party was brought to an end at Culloden, where the duke of Cumberland defeated Charles Edward. The cruelties with which the Jacobites were punished reflect discredit on the English name. The treaty of Aix la Chapelle in 1748 restored peace to Europe for a few years. The whigs continued to rule, headed by Henry Pelham, and after his death in 1754 by his brother the duke of Newcastle. The renewal of the war with France in 1755 led to considerable ministerial changes, and in 1757 was formed the celebrated Pitt-Newcastle ministry, which carried on the contest with great vigor; so that when George II. died, Oct. 25, 1760, his fleets and armies were everywhere triumphant. The foundation of the East Indian empire of England was laid at Plassey, June 23, 1757. French America was conquered at Quebec, Sept. 13, 1759. The victories of Minden and Crefeld atoned for the days of Laffeldt and Fontenoy. Hawke's victory over Conflans was one of the noblest exploits of the British navy. The victories of Frederic of Prussia were quite as much owing to English money as to German genius. Death arrested the policy which had produced such results. The new king, George III. (the first English-born prince who had been on the throne since 1714), grandson of George II., was by nature as despotic as the worst of the Stuarts, and, having been educated in principles utterly unfit to be held by a constitutional sovereign, he resolved to attempt the restoration of Stuart modes of government; and hence peace was his first object, not because he had any aversion to bloodshed, but that he might be at liberty to concentrate all his powers on the work of internal change. He got rid of Pitt and made peace, but not until he had waged a brief war with Spain, that country joining the French in the last stage of the contest. The treaty was held to be very disgraceful to England, but history hardly bears out contemporary opinion, though it certainly was unwise to give up such islands as Martinique, Cuba, and the Philippines. Scarcely more wise was it to retain Canada, whereby the English North American colonies were freed from any fears from French attacks, and any feelings of independence which they might have would be increased. Those colonies, however, would probably have been long in maturing the wish for separation from the parent country had

they been well governed. With the exception of a few thoughtful men, the colonists were attached to the home government as sincerely as were the dwellers in Lancashire and Kent. The attempt of that government to tax them caused great indignation, and led to the American revolution, which ended in the dismemberment of the empire. The English in the last years of the war had to fight the Americans, the French, the Spaniards, and the Dutch. The peace of 1783 left England in a low condition, from which however she rapidly recovered. She had been fortunate only in the East, where the ability and unscrupulousness of Warren Hastings increased her power. Shortly after the conclusion of the war George III. became popular, and saw the party which he hated excluded from office. The new phase of toryism which manifested itself under the rule of the younger Pitt became the ascendant political principle of England for more than 40 years. When the French revolution broke out, the English ministry reluctantly engaged in the war that soon followed, a fact that is established by the total want of preparation that marked the condition of England in 1793. A portion of the aristocratic whigs, headed by Burke, were more anxious for war than were Pitt and his immediate followers. The war lasted, with two brief intervals, down to the summer of 1815, ending in the complete triumph of England and her allies. The exertions made by England were vast, though her actions were not always wise. Her fleets, led by Nelson, Jervis, Howe, and Duncan, achieved splendid victories over the French and Spaniards, and in the last years of the war her armies were greatly distinguished under the lead of Wellington and others. In 1812-'15 she was involved in war with the United States, growing out of the impressment and right of search questions. Her colonial and Indian dominions were much extended during the contest. On the other hand, she found herself burdened with a debt of \$4,000,000,000, and her expenditures had been on the most gigantic scale. George III. lost his reason finally in 1810, and for more than 9 years his eldest son, afterward George IV., was prince regent, succeeding to the throne Jan. 20, 1820. After the restoration of peace in 1815, England entered upon a career of reform which has been more or less steadily followed ever since, and which, without causing any disturbance to society, has wrought important changes, and greatly improved the condition of the people. This reform at first related to commercial and legal matters, but soon reached to others which are considered to be more peculiarly political in their character. The high toryism of the government underwent a change, and on the death of Lord Castlereagh in 1822, that liberal course in foreign politics was commenced by England which has been substantially maintained until now, and promises to be permanent. The passage of the Catholic emancipation act in 1829, under direction of a ministry headed by Wellington and Peel, showed that religious bigotry was no longer to receive

the direct countenance of government; and the proceeding was but the fulfilment of the spirit of the treaty by which Ireland had been united to Great Britain in 1801, and, her own parliament abolished, allowed to send members to the imperial parliament. George IV., who had begun life as a liberal in politics, opposed this act, but was compelled to yield to the pressure brought to bear upon him by the tory chiefs. He died the next year, 1830, and, having no legitimate children, was succeeded by his brother the duke of Clarence, as William IV., whose short reign was destined to be the time of more political agitation than had been known since the revolution. Immediately after he became king happened the French revolution of July, 1830, which was followed by outbreaks in other parts of Europe, especially in Belgium and Poland, against established authority. England felt the effect of these movements, and sympathized with the popular parties of the continent. Parliamentary reform had long been desired by many of her people, and from time to time efforts had been made to accomplish it, but rarely with spirit, and never with success. But in March, 1831, a reform bill was introduced into the house of commons by Lord John Russell, and after long debates in parliament and intense excitement in the country, caused by the opposition of the house of lords, a bill making extensive changes in the constitution of the house of commons finally passed in June, 1832, under the ministry of Earl Grey. The first reformed parliament, which met Jan. 29, 1833, contained an overwhelming majority of reformers. The dominant party however was too strong, and fell from its own weight. Irish troubles led to dissensions, and Lord Grey retired from office in 1834. He was succeeded by Lord Melbourne. Toward the close of the year Earl Spencer, father of Lord Althorp, died, causing a vacancy in the chancellorship of the exchequer, which Lord Althorp could not hold as a peer. The king, who had been watching for an opportunity to get rid of the whigs, took this occasion to dismiss the ministry. The government was committed to Sir Robert Peel, who formed a conservative ministry, and made a bold effort to retain power, though it is not probable he would have advised the king to the step he had taken in dismissing the Melbourne ministry, for there were not 200 men in the commons who would have preferred the conservatives to the whigs. Parliament was dissolved, and in the elections that followed the conservatives gained largely; but the reformers had a majority, so that, though 35 reformers voted for the Peel candidate for speaker of the house of commons, he was beaten by a majority of 10. Sir R. Peel continued in office until April 8, 1835, when he retired, having been repeatedly beaten on Irish church questions. His ministry had not lasted 5 months. Lord Melbourne returned to office, with many of his old colleagues. The king found himself forced to submit to the whigs, and he did so with as much grace as possible, and never made an open

attempt to disturb them; but it is said he was prepared to do something against them when he was seized with that illness which proved fatal to him, June 20, 1837. He was succeeded by his niece, the princess Alexandrina Victoria, who took the title of Victoria I. She was the only child of Edward, duke of Kent, 4th son of George III. This event led to the separation of the crowns of England and Hanover, which had been worn by the same persons since 1714, the Salic law prevailing in Hanover. The queen was very popular when she ascended the throne, nor have 22 years produced any abatement of that popularity, the love of her subjects and the esteem of foreigners being fully justified by her conduct, which has ever been that of a humane and constitutional sovereign. She favored the whig ministry, which remained in office some 4 years after her accession, though often rudely shaken, and once compelled to resign for a few days. The elections held on the demise of the crown did not strengthen the ministry, and they ruled on sufferance. There was a near approach to war with France in 1840, in consequence of disputes on the eastern question. Could France have looked anywhere for an ally, war would probably have broken out; but all the great powers were arrayed against her, nearly as closely as they had been in 1815. In 1841 the long contest between the conservatives and the whigs came to a crisis, and after the latter had been more than once defeated, the house of commons declared its want of confidence in them by a vote of 312 to 311. Shortly afterward parliament was dissolved, and the subsequent elections ended in a complete conservative triumph. When parliament met, the ministers were beaten by 91 majority in the commons, and by 72 in the lords. They immediately resigned, and Sir R. Peel formed a conservative ministry, destined to destroy many things which conservatives held dear. The whigs, just before they had been expelled, had adopted the part of corn law reformers, and the voice of the country was beginning to make itself heard on this question of food. In many respects the minister showed himself a reformer. He freed many articles from duties, and in other ways approximated to the position of a free trader. The more intense conservatives were dissatisfied, but the course of events was too much for them. The famine of 1845 compelled the ministry to discontinue their support of the protection policy, and the anti-corn-law league received much aid from the potato rot. The minister resigned office, but was compelled to resume it, and to preside over the destruction of the corn laws, which were finally disposed of, June 26, 1846. The "league" was immediately dissolved. The Peel ministry had from the first experienced much difficulty in the management of Irish affairs. The Melbourne ministry had pursued a liberal course toward Ireland, and received the support of Mr. O'Connell and his friends; but when the conservatives came into office, the Irish leader, between whom

and the premier the utmost personal dislike existed, resumed the work of "agitation." He brought forward the repeal question, and monster meetings were held in various parts of Ireland, at which enormous numbers were present. Government interfered to prevent one of these meetings at Clontarf, Oct. 8, 1843, with perfect success. Mr. O'Connell, one of his sons, and 8 other persons, were arrested on charges of conspiracy, sedition, and unlawful assembling. They were tried and convicted, and Mr. O'Connell was sentenced to a heavy fine and a year's imprisonment, and required to find high recognizances to keep the peace for 7 years. The case was carried before the house of lords, where 3 law lords voted for the reversal of the judgment of the lower court, and one (Brougham) to retain it (Sept. 4, 1844). The 3 were Lords Denman, Cottenham, and Campbell. Though nominally beaten, government was really victorious, as from that time Mr. O'Connell's influence was essentially diminished. In 1846 the Peel ministry brought forward an act to protect life in Ireland, but it was defeated in the commons on the same day that the corn laws were repealed, and the ministry came to an end, being succeeded by one at the head of which was Lord John Russell, which lasted down to the early part of 1852. The Russell ministry ruled England through the crisis of 1848-'9, and did not find the task difficult, because the constitutional principles on which the people had been so long governed had rendered revolution unnecessary. A weak attempt to get up an insurrection in Ireland was put down, and the chiefs in it were transported. The Russell ministry went out of office in 1852, and for several months the tories, led by Lord Derby and Mr. Disraeli, were at the head of affairs. This ministry was followed by one composed of coalesced whigs and Peelites, headed by Lord Aberdeen. In 1853 the troubles on the Turkish question began, and war was declared against Russia by France and England, March 28, 1854. Large fleets and armies were sent to the East, and fleets to the Baltic. The Crimea was invaded, the victory of the Alma won by the allies, and Sebastopol partially invested. The Russians made great exertions, and having brought up large forces, fought the battles of Balaklava and Inkermann, losing them both. They were more successful in defending Sebastopol, the allies' attacks on which proved total failures. Winter set in, and great sufferings were experienced by the besiegers. Alarming accounts of the condition of the army were furnished to the London newspapers by their correspondents, and were corroborated by private letters. Though the allies had destroyed Bomarsund, in the Aland islands, their expedition to the Baltic had failed. Much irritation existed in England, under the effect of which the Aberdeen ministry broke down, and was succeeded by one at the head of which was Lord Palmerston, from whom the people expected as

much as their ancestors had received from Pitt a century earlier. The war was continued in the Crimea during the winter, but little progress was made in the siege. In the spring increased vigor was infused into operations, and some brilliant successes were achieved; but on June 18 both French and English were repulsed in attempting to storm the Malakoff and the Redan. Lord Raglan, the English commander, died soon after, and was succeeded by Gen. Simpson. Preparations for a final attack were now made, and in September the city was subjected to the most terrible cannonading known in the history of war. On the 8th the French stormed the Malakoff, but were beaten on all other points of attack, while the English failed before the Redan. The Russians abandoned southern Sebastopol, retreating to the north side, whence no serious effort was ever made to dislodge them. They submerged their fleet, and they and the allies destroyed what was left of the town, and its fortifications and splendid docks. Kinburn was taken by the allies, and Kars was taken by the Russians. But the war was now virtually at an end, and peace was restored by a congress of the great powers at Paris, in March, 1856. England reluctantly made peace, her people having entered upon the war with the determination to put an end to that supremacy which Russia had exercised over Europe since the fall of Napoleon. The war had served to show her power and her credit, and it had also exposed some of her weaknesses. It was as well for her, however, that peace was restored, for not much more than a year after that event, and while engaged in hostilities with Persia and China, a conspiracy was forming in her great Bengal army of sepoys, which broke out in Jan. 1857, and was attended with circumstances that shocked the world. Delhi, the old capital of the Moguls, fell into the hands of the sepoys, and the nominal Mogul emperor found himself once more a sovereign in reality. The mutiny spread rapidly, and in a short time the whole Bengal army had become, with few exceptions, an army as hostile to the English as those which had fought against them at Wandiwash and Assaye. The particulars of the contest that followed, and which in less than 2 years led to the reestablishment of the English ascendancy, this is not the place to relate. Suffice it to say that they showed the idleness of the assertions that England had become powerless, and that the skill, valor, and endurance of her people had declined. Her military reputation, which had been lessened in the eyes of many by the events of the Russian war, was greatly raised by the successes of her armies in India, and the valor and fortitude displayed on almost every critical occasion by her sons; while the statesmanship that was exhibited in the Purjaub showed that it is in her power to rule India with wisdom, firmness, and humanity. In 8 months after the breaking out of the mutiny, there were nearly 70,000 effective English troops in India,

and new native corps had replaced the sepoy. By the end of 1858, this formidable revolt was totally suppressed, and the few mutineers that remained were reduced to the condition of wandering brigands. Major-General Sir Henry Havelock particularly distinguished himself in this war, but did not live to see its conclusion. After defeating the sepoy in 9 pitched battles, he died at Lucknow, Nov. 25, 1857. The war was concluded by the generalship of Sir Colin Campbell, who was raised to the peerage as Baron Clyde for his services. The government under which measures so thorough had been initiated became, however, unpopular, because it was supposed to be too subservient to that of France. A hostile vote in the house of commons in Feb. 1858, drove the Palmerston ministry from office, and a new conservative ministry was formed, with the earl of Derby as premier, and Mr. Disraeli as chancellor of the exchequer. A new reform bill was brought forward by this ministry in Feb. 1859. It was not acceptable to the friends of reform, and was defeated in the house of commons, March 31, 1859. Parliament in consequence was dissolved, and an appeal made to the country. The result of this election was a considerable gain to the Derby ministry.—*English Constitution.* The English constitution, which the English people are accustomed to speak of as the envy of other nations, is very ancient, though the present constitution is to that under which England "flourished 500 years ago, what the tree is to the sapling." The commencement of the English polity must be looked for in the time of the Roman occupation of the island, for that occupation was not only important in itself as a grand civilizing agency, but it had its effect on those Germanic conquerors whom we call Anglo-Saxons. The theory that the Saxons, while destroying the male Britons, spared and married their women, is plausible, and is supported by the fact that something of the same kind has been done by other conquerors under similar circumstances. This would give to England an important Celtic element. The invaders probably occupied the Roman towns, though a high authority (Kemble) is of opinion that they allowed those towns to perish. The conversion of the Anglo-Saxons to Christianity was an important step toward their civilization, and developed those ideas of order and law which belong to the race of which they were members, in an eminent degree. They were gradually forming a Christian state, when the arrival of the Danes gave a new turn to events, and contributed in making that England which the Normans seized in the 11th century. The Danish element was favorable to the production of a free state. All the circumstances of England during the 6 centuries that followed the Roman abandonment of the island tended to the formation of the polity which now exists there, and which was first clearly pronounced in the 13th century. Both the aristocratic element and the democratic element

entered into the Saxon polity, the former attaining to a decided predominance. The free classes were divided into thanes and ceorls, the former being nobles and gentry, and the latter the mass of the people. The possession of property determined the position and rights of the freemen. The thralls were slaves, but are supposed not to have been numerous. The local organizations regulated for the most part their own affairs. The country was divided into counties, the counties into hundreds, the hundreds into tithings. The county courts, and those of the hundreds, were popular tribunals. The witenagemote was the highest assembly, and was thoroughly aristocratic in its character. The king presided in it, and it met by his summons. The earls—nobles by birth, as the thanes were from possession of property—attended it, and so did bishops and abbots. The thanes, too, had the right to sit in it. The local magistrates are supposed to have been occasionally present. The people had no part in it, and were not represented. It made laws, and voted taxes when they were needed. It controlled the king, and could elect him from among the members of the royal line. It was the highest court in all cases. The clerical influence in it was great, as it was throughout the country. The idea that the witenagemote was the original of parliament, though once entertained, is now entirely given up; yet it is apparent that it had some of the elements of parliament, and that its existence was not without effect in helping to form the polity that now exists. The Saxon aristocracy increased their power as time went on, and many believe that if the Normans had not conquered England that country would have seen all power pass into the hands of the great nobles. The higher earls were fast becoming rulers of the state, when they and the peoples, Saxon and Danish, were all subdued by another northern race, which had materially changed its character by a long residence in France. The conquest effected great changes in England. The feudal system was unknown there previous to that event, though the elements of feudalism were not altogether absent from it. William I. introduced this system into England, but with such modifications as prevented the sovereign from being enslaved by the nobility. This he could not have done had he found feudalism existing in the island, for in that case he would have had to conform to the general character of the system. The theory that the king of England is the supreme lord of all the land, which exists now, and has existed for nearly 8 centuries, was established by the conqueror. This supremacy was directly and solemnly admitted by all the landed men of England in 1086, in an assembly at Salisbury. All took the oath of fealty, and did homage. The lands the king conferred on his followers were scattered over the country, so that it was impossible for his tenants *in capite* to increase into territorial potentates, such as existed in France

and elsewhere on the continent. He kept up the Saxon courts, but withdrew from the county court cognizance of ecclesiastical matters. These popular courts were made more popular by William than they had been under the Saxon kings. The king's courts were also important tribunals. This judicial system tended to keep down the baronial courts, which were always of inferior rank to the baronial courts of the other European countries. The English barons themselves never attained, in any respect, to the consequence which barons achieved elsewhere. Half the people were slaves, living in villeinage. Those attached to the soil, like Russian serfs, were villeins *regardant*, while the others, who could be disposed of like the negro slaves in our southern states, were villeins *en gros*. The number of the latter was not large. This state of things was brought about in the 90 years that followed the conquest, and was the result of the Norman rule, the English peasants being reduced to the condition of those of Normandy. In the reign of Henry II. the work of redemption began, and for 7 centuries progress has been the law of England, though sometimes it has been very slow in manifesting itself. Judicial interpretation was favorable to the enslaved classes. At the beginning of the 18th century there was a class of free laborers in England, small in numbers, but embracing the humbler people of the towns, and some of the peasants. The free peasant, no matter how complete his poverty, was compelled to be enrolled in the *decenna*, or subdivision of the hundred to which he belonged, and performed certain political duties of a local nature. He could act on inquests or juries. The landholders were tenants in chivalry, or holders by military tenure, and included the barons and other great men holding immediately of the crown, and whose burdens were as great as their honors; tenants in free socage, who have been compared with the modern yeomanry, and whose condition was as good as that of any class of men in that time; and tenants in villeinage, men who had been emancipated, and who continued to reside on their old places, rendering their old services, or freemen who had taken their places on the condition of discharging their obligations. There were not many of this last class of holders at the commencement of the 18th century. The conquered towns had passed into the hands of the Normans, but had managed to obtain a certain degree of freedom, by purchase, and also by charters, yet were liable to be specially taxed for the benefit of their lords. Such was the condition of England when John became king, and carried the ordinary Norman tyranny to an extent that never was thought of by any of the preceding kings. A council of barons and prelates was held in 1213, at which Langton, archbishop of Canterbury, brought forward a charter of Henry I., which was well received. Another council was held in 1214-'15, which extorted Magna Charta from the king. The charter itself is dated June 15, 1215 but

the conference was not concluded until the 19th. The great charter, one of the landmarks of the history of freedom, laid the foundation of the English constitution in its broad and definite sense. It was renewed, with some omissions, in the reign of Henry III., who also granted the charter of the forest, modifying the forest laws of the country. These charters were renewed 5 times in the same reign. The charter of Henry III. has been 30 times confirmed. The most remarkable of these confirmations was in the 25th year of Edward I. The government, as established in the 13th century, provided for a hereditary monarch with limited powers, taxation by parliament, punishment to be inflicted only after lawful trial, the cessation of arbitrary fines and imprisonment, trial by jury, and justice without price or delay. Parliament attained to the distinctive character which it has had for 595 years in 1265, when borough representation was created. Knights of the shire were earlier summoned to the great council, which was called parliament in 1246. It was the intention of those who framed Magna Charta that cities and boroughs should be represented, but 50 years elapsed before their plan was carried out. Councils without burgesses continued to meet for some time after the establishment of parliament. That England obtained a symmetrical constitution in the 13th century, or that she has ever had any thing of the kind, is not pretended by the most partial vindicators of her polity; but it is claimed, with strict justice, that then she became distinctly a free state, and that since that time she has been able to maintain liberty and order to an extent, and for a length of time, unknown to any other country. Monarchs and ministers frequently disregarded the restraints placed on them by the laws, but not even the most arbitrary of kings or the most reckless of ministers has ever dared to go beyond a certain line, save to be destroyed. The constitution continued to develop itself, and early in the 14th century we find the house of commons a great admitted power in the state. In the reign of Edward III. this body complained of the conduct of the king's ministers, and in 1376 the first impeachment took place, applying to 6 persons, 2 of them peers, who had been employed in the fiscal department. In the affairs of war and peace the commons were then frequently consulted. It was provided that there should be frequent sessions of parliament, and 48 were held in the reign of Edward III. The minority of Richard II., and his weakness when he became of age, favored the growth of the power of the commons. That king sought to "pack" the house in 1398, a plain proof of its consequence. Parliament aided to depose Richard II., and to confer the crown on Henry IV., over the superior claim, in a legitimate sense, of the line of Clarence. Hallam, speaking of things as they were at the close of the 14th century, says: "Of the 3 capital points in contest while Edward III. reigned: 1, that money could not be levied; 2, or laws enacted

without the commons' consent; and 3, that the administration of government was subject to their inspection and control—the first was absolutely decided in their favor, the second was at least perfectly admitted in principle, and the last was confirmed by frequent exercise." In the 9th year of Henry IV. it was recognized that all money bills must originate in the lower house, and that the king should not take cognizance of the subject of that body's deliberations until it had decided upon it, and brought its decision before him regularly. Freedom of speech was reluctantly allowed by the sovereign, and Henry IV. did what he could to prevent it; and in the reign of Henry VI. a member of the commons was imprisoned because of a motion he had made; but as that motion related to the succession to the throne, and was made not long before the outbreak of the wars of the roses, perhaps the severity exercised toward him was owing to the jealousy which the Lancastrians felt toward the Yorkists. Members were then first privileged from arrest. Laws were passed to lessen the influence of the crown in elections, and to determine the qualifications of voters and representatives. At this time the desire to enter parliament was commonly felt, whereas in the preceding century it had been found necessary to enforce the election of representatives, while electors complained of the burden of paying members. The wars between the houses of York and Lancaster raised the consequence of the house of commons, as each party had to appeal to that body, and employed the power of parliament against its enemies. In 23 Henry VI. it was sought to provide that knights of the shire should be of gentle birth, but the law could not be enforced. Had this passed into practice, and become a portion of the constitution, the course of English history must have been entirely changed. It is owing to that liberal character of her aristocracy that England is both aristocratical and liberal in her government. There was in England, in the 15th century, "a strong hereditary aristocracy; but," says Macaulay, "it was of all hereditary aristocracies the least insolent and exclusive. It had none of the invidious character of a caste. It was constantly receiving members from the people, and constantly sending down members to mingle with the people. Any gentleman might become a peer. The younger son of a peer was but a gentleman. Grandsons of peers yielded precedence to newly made knights. The dignity of knighthood was not beyond the reach of any man who could by diligence and thrift realize a good estate, or who could attract notice by his valor in a battle or a siege. It was regarded as no disparagement for the daughter of a duke, nay, of a royal duke, to espouse a distinguished commoner. Thus Sir John [Sir Robert] Howard married the daughter of Thomas Mowbray, duke of Norfolk. Sir Richard Pole married the countess of Salisbury, daughter of George, duke of Clarence. Good blood was indeed held in high respect,

but between good blood and the privileges of peerage there was, most fortunately for our country, no necessary connection. Pedigrees as long, and escutcheons as old, were to be found out of the house of lords as in it. There were new men who bore the highest titles. There were untitled men well known to be descended from knights who had broken the Saxon ranks at Hastings, and scaled the walls of Jerusalem. There were Bohuns, Mowbrays, De Veres, nay, kinsmen of the house of Plantagenet, with no higher addition than that of esquire, and with no civil privilege beyond those enjoyed by every farmer and shop-keeper. There was therefore no line like that which in some countries divided the patrician from the plebeian. The yeoman was not inclined to murmur at dignities to which his own children might rise. The grandee was not inclined to insult a class into which his own children must descend." Had the plan to confine county representation to persons of gentle birth been successful, this liberal state of things must have come to an end, and the English aristocracy have degenerated into a mere oligarchy, to have been in its turn subdued by some powerful king. It was owing to the general liberality of the English system of 400 years ago that the plan failed, the law falling into desuetude, and the course of England's development being left without a check. It would, however, be wrong to infer from the real power and great consideration of parliament, that the king was not a sovereign of the first rank. He was very powerful, and did many things which we, with our modern ideas of law and regularity, find it very difficult to reconcile with the idea of the chief of a constitutionally governed country. Much depended on personal character, but even the weakest of kings possessed great prerogatives, and found not much difficulty in occasionally evading or violating the law, without causing public commotion. With 3 or 4 exceptions, all the English sovereigns that reigned between the days of Hastings and Bosworth were men of distinguished talents and much energy; facts that explain why it was that the liberal principle made no greater progress, and also show how earnest the English must have been in laboring for free institutions, which could have been gained by no ordinary means from monarchs of such abilities, and who were naturally averse to every thing that tended to lessen their authority. The belief, once so common, that the Tudors established a despotism in England, and that for 3 generations and more the polity of the country became less liberal than it had been under the Plantagenets, cannot now be justly entertained. There were great changes made in various respects, but that the government was as arbitrary as has often been stated is not the fact. It had that appearance because those intrusted with it were careful not often to go further in their exactions than public opinion would warrant their going. "In the house of commons, then as much as now," says Froude,

"there was in theory unrestricted liberty of discussion, and free right for any member to originate whatever motion he pleased. But so long as confidence existed between the crown and the people, these rights were in great measure surrendered. The ministers prepared the business which was to be transacted; and the temper of the houses was usually so well understood that, except when there was a demand for money, it was rare that a measure was proposed the acceptance of which was doubtful, or the nature of which would provoke debate. So little jealousy, indeed, was in quiet times entertained of the power of the crown, and so little was a residence in London to the taste of the burgesses and the country gentlemen, that not only were their expenses defrayed by a considerable salary, but it was found necessary to forbid them absenting themselves from their duties by a positive enactment." Henry VIII., writing to the pope in 1529, said: "The discussions in the English parliament are free and unrestricted; the crown has no power to limit their debates, or to control the votes of the members. They determine every thing for themselves, as the interests of the commonwealth require." Henry had a motive to make the pope believe in the power of parliament, but he was too sensible a man not to be aware that the papal court had excellent intelligence, and that it would be the extreme of folly to attempt to impose upon it. Throughout the entire existence of the Tudor dynasty there were instances of the sovereigns retreating from positions they had assumed when they found they had done what was unpopular; and they retreated so well as always to save their dignity, and to prevent their prerogatives from being called in question. The resistance which the Tudors experienced when they endeavored to tax their subjects too highly can leave no doubt that the power of the people was as great as ever it had been, and that the new dynasty, whatever else it succeeded in changing, did not effect any change in the English character. They certainly bore hard upon the aristocracy, but this rather helped them with the people. The peerage was not then extensive. Frequent mention has been made of the first parliament of Henry VII. having contained but 29 temporal peers, while in the parliament of 1451 there had been 53 such peers; from which it has been inferred that the aristocracy had been nearly annihilated in the wars of the roses. Unquestionably it had suffered immensely in those wars, which were contests between aristocratical factions, but there was abundant material from which to have filled the house of peers, had the king been desirous of filling it. The Tudors greatly changed the character of the aristocracy, not only by striking down many of the noblest of its members, as the Roman emperors had served the relics of the republican aristocracy, but also by elevating men from among the gentry and lawyers. The names of Russell and Seymour are now among the noblest in England, but they

were not noble until the time of Henry VIII., or later. The Dudleys then rose to note. But whether new or old, the aristocracy were the true serviles of the Tudor times, not the people. One of the proofs that the parliament was not a feeble, inconsequential body even under Henry VIII., the most arbitrary of all the Tudors, is to be found in the use which he made of that body on many occasions. That monarch, as Bolingbroke says, "by applying to his parliaments for the extraordinary powers which he exercised, and by taking these powers for such terms and under such restrictions as the parliament imposed, owned indeed sufficiently that they did not belong of right to the crown. He owned likewise in effect, more than any prince who went before him, how absolutely the disposition of the crown of England belongs to the people of England, by procuring so many different and opposite settlements of it to be made in parliament." It has been observed that the increased weight of the commons in the Tudor reigns is proved by the desire of the government to obtain victories at elections. New boroughs were then created for the express purpose of adding to the government's influence in the house of commons, and to this action is attributed the irregularities that have existed in the popular representation of England. Government interfered in elections, and bribed members of the house. Henry's daughter, Mary, dissolved two parliaments, because they would not do what she desired; and the third was not always compliant. The abbey lands could not be restored to the church, nor the English crown settled on Philip II., because of the hostility of parliament to both schemes. These facts, and others that might be quoted, show that the government of the Tudors was not altogether of that despotic character that it has often been represented. They were more arbitrary sovereigns than the Plantagenets, and they carried much further than their predecessors the usurped jurisdiction of the court of star chamber. That famous tribunal interfered with the common course of justice so far as well nigh to hold all authority, and nearly destroyed the value of trial by jury by its arbitrary treatment of honest jurors. The reformation had great political effects, the chief of which was the increase of the power of the crown. Henry VIII. was pope of England for a time as well as king. His ecclesiastical supremacy was exactly what the words mean; but this was owing to circumstances and to his personal character, and his system died with him. When the Anglican church was finally established under Elizabeth, the sacerdotal character of the sovereign was disclaimed; but she had a vast power over the church in her hands, the ecclesiastical jurisdiction of the crown being complete. "The act of supremacy," says Hallam, "empowered the queen to execute it by commissioners appointed under the great seal, in such manner and for such time as she should direct; whose power should extend to visit, correct, and amend all heresies, schisms,

abuses, and offences whatever, which fall under the cognizance and are subject to the correction of spiritual authority." After several temporary commissions had sat under this act, the high commission court came into existence in 1588. A more arbitrary tribunal never existed, and it is easy to see that men should suppose it could be favored only by a despotic government. Burleigh opposed the procedure under it, but, influential as he was, his opposition availed nothing. The house of commons was hostile to the high ecclesiastical party, and the tone which its opposition took was not that of a servile body. Yet it is from the pen of one of the worst of the bishops that we have the clearest proof of the nature of the English government in the 16th century, to the point that it was not arbitrary. "The regiment of England," says Aylmer, afterward bishop of London, "is not a mere monarchy, as some for lack of consideration think, nor a mere oligarchy, nor democracy, but a rule mixed of all these, wherein each one of these have or should have like authority. The image whereof, and not the image but the thing indeed, is to be seen in the parliament house, wherein you shall find these three estates: the king or queen which representeth the monarchy, the noblemen which be the aristocracy, and the burgesses or knights the democracy. If the parliament use their privileges, the king can ordain nothing without them; if he do, it is his fault in usurping it, and their fault in permitting it. Wherefore, in my judgment, those that in King Henry VIII.'s days would not grant him that his proclamation should have the force of a statute, were good fathers of the country, and worthy commendation in defending their liberty." This was written in 1559, the 1st year of Elizabeth and the 74th of the Tudor rule; and it is not possible that it could have been written had England been despotically governed by the Tudors. To the same purport are the observations of a far greater writer of the Elizabethan time, made in its last days. "I cannot choose," says Hooker, "but commend highly their wisdom, by whom the foundation of the commonwealth hath been laid; wherein, though no manner of person or cause be unsubject unto the king's power, yet so is the power of the king over all and in all limited, that unto all his proceedings the law itself is a rule." Hallam sums up the whole subject by saying that the English constitution under the Tudors "was a monarchy greatly limited by law, but retaining much power that was ill calculated to promote the public good, and swerving continually into an irregular course, which there was no restraint adequate to correct. It may be added, that the practical exercise of authority seems to have been less frequently violent and oppressive, and its legal limitations better understood, in the reign of Elizabeth than for some preceding ages." Hence, when the house of Stuart succeeded to that of Tudor, it did not become the head of a despotically governed state, but

of a constitutionally ruled kingdom. The contest that then commenced, the opening scene of the English revolution, was the work of the government, and the revolutionary party consisted of that government and its adherents. The "country party," as the opposition came to be called, was, in the strictest sense of the word, a conservative party; and if, in the course of the long struggle of 86 years, it had occasional resort to acts of an apparently revolutionary character, it was only because they were necessary to the success of the one object it had in view, namely, the preservation of the liberties of England. In England, as afterward in America, the security of liberty was found compatible only with the removal of that government which had assumed the destructive part, and which would have overthrown the last of those constitutions of which there had formerly been so many in Europe, the English constitution being only one of a large family of similar polities, and the last survivor of them. The divine right theory, which was so zealously preached in the reign of James I., was meant to prepare the way for the subjugation of the people, and for the concentration of all power in the hands of the central authority. Charles I. was bent upon not being a Venetian doge, and some really able modern writers have written as if they believed there was a close resemblance between a king of England, who had only to rule according to law and his oath, and the shadowy phantom, that did not even play at ruling, on the Adriatic. A very great measure of power has always been wielded even by the most constitutionally inclined English monarchs, and popular feeling has often been with such kings against the aristocracy, but always on the condition that the king ruled according to law, a fact that it was impossible for Charles I. to comprehend. The contest was for power over the purse; which secured, power over the sword followed as of course. The 8d parliament of Charles I. passed the Petition of Right, an instrument superior to Magna Charta itself, and to which the king gave his consent. In it are pointed out the breaches that had been made in the law, the constitutional rights of Englishmen are declared, and the king is prayed to rule legally. Even if there had been a despotism in England previous to 1629, it ought then to have come to an end, after king and parliament had solemnly agreed upon the terms on which the government should thereafter be carried on. Yet the king violated the Petition of Right in the most flagrant manner, and did not call a parliament for 11 years, which was unprecedented. During that time, England was as arbitrarily governed as France by Richelieu, without having any glory, like that which Richelieu's foreign policy was gaining for France, to gild her chains. The machinery of despotism was found to be perfect within certain limits, and those by no means narrow ones. The jurisdiction of the court of star chamber was very great, and the proceedings in that court were

more numerous and violent than they had been under the Tudors; and "the object of drawing so large a number of criminal cases into the star chamber seems to have been twofold: 1, to inure men's minds to an authority more immediately connected with the crown than the ordinary courts of law, and less tied down to any rules of pleading or evidence; 2, to eke out a scanty revenue by penalties and forfeitures. Absolutely regardless of the provision of the great charter, that no man shall be amerced even to the full extent of his means, the councillors of the star chamber inflicted such fines as no court of justice, even in the present reduced value of money, would think of imposing." The cruel, atrocious punishments inflicted by the star chamber are as well known as the sentences passed at the bloody assizes. The council of the north, which had been created by Henry VIII., but which for 96 years had comparatively limited powers and jurisdiction, was converted into a star chamber for all that part of England which lies between Humber and Tweed. Wentworth, the president of this council, contrived to make it even worse than it would have been under the presidency of any other man. Proclamations were frequently resorted to, and were made to have the force of law. They intermeddled with almost every department of life, to the great grievance of the subject. Yet nothing can be clearer than their unconstitutionality; and until the Stuart age they were but little known. James I. made them common, and his evil example was outdone by his successor. The case of ship money has attracted extraordinary attention, which is in part due to the character of Hampden; but it was one then calculated to excite all men's attention in itself, for it showed that no dependence could be placed on the common law courts, and that those tribunals were nearly as bad as the irregular tribunals which Charles, and Wentworth, and Laud employed to plunder the property, to restrict the liberty, and to mutilate the persons of Englishmen. "Ship money," says Hallam, "was held lawful by Finch and several other judges, not on the authority of precedents, which must in their nature have some bounds, but on principles subversive of any property or privilege in the subject. These paramount rights of monarchy, to which they appealed today in justification of ship money, might tomorrow serve to supersede other laws, and maintain new exertions of despotic power. It was manifest by the whole strain of the court lawyers, that no limitations on the king's authority could exist but by the king's sufferance. This alarming tenet, long bruited among the churchmen and courtiers, now resounded in the halls of justice." A reconciliation was sought with Rome, and Catholic troops were to be employed to control the Scotch and English. Even had there been no religious grievances to complain of, the political grievances were so vast and so various, that they would have justified a resort to arms on the part of all who cared for consti-

tutional government. But there were religious grievances in abundance, though so "thorough" had been the repression exerted by Laud, that he could report to his master a most happy absence of nonconformity in 1639, "on the very eve of a revolution, in which primate and church, and monarch and monarchy, were to perish together." The religious element had much to do with bringing about the contest that commenced in 1640. The 4th parliament of Charles I. met in April, and was soon dissolved; and 6 months later met the most memorable parliament that ever assembled. That parliament fought the battle of the constitution, and fought it successfully. The entire machinery of despotism was broken down, most of it never to be rebuilt. The star chamber, the council of the north, and the high commission court disappeared from England, the first two forever, and the last to be only temporarily revived by James II. This would have ended the quarrel could the king have been trusted. But to trust him was quite out of the question, and parliament, to preserve the freedom of the country, had to resort to measures which were unconstitutional, according to the letter of the constitution, but perfectly in keeping with its spirit. The king was forced to agree that parliament should not be dissolved without its own consent, which was an invasion of his prerogative; and later it was resolved that no minister should be appointed or peer created without the consent of parliament, and that the king should be made to resign the supreme military authority, which he justly held to be the very flower of the crown, and which was unquestionably one of its most ancient attributes. This conduct, indefensible on mere technical grounds, was proper in reference to the object had in view, which was to put an end to illegal government by the king, who had repeatedly proved himself incapable of keeping his word. War soon broke out, and the king was supported by a large number of constitutionalists, men who were prepared to maintain the government as it was after the early reforms of the long parliament had been accomplished, but who dreaded innovation. Had they been successful, the constitution would assuredly have been destroyed, though nothing was further from their intention; while the innovating party were pursuing the only course that could lead to its preservation. The war led to the suspension of the constitution, and the protectorate of Cromwell was mainly a government by the sword, in spite of the fact that the protector sincerely wished to rule as a constitutional monarch. In 1660 the house of Stuart was restored, but unfortunately without any thing having been done to secure the enjoyment of legal rule. The old polity came once more into full force. The government was what it had been, nominally, before Charles I. and parliament appealed to the sword, so that the star chamber and high commission courts, and other institutions of tyranny, no longer had place in England. Tenures by knight service were abolished, and most

of the soil of England was held under that tenure. The parliament of 1661, which lasted down to 1679, was fanatically attached to royalist principles, and to its fanaticism must the bad government of Charles II. in no small degree be attributed. His reign is one of the worst in English history, but his first parliament was as bad as the king. Yet in that reign much was done that had permanent effect on the constitution. The dispensing power was condemned by parliament, and its illegality admitted by the king himself. The test act was passed. The *habeas corpus* act, which supplied a proper system of procedure to preserve the liberty of the subject, was adopted, and received the support of all Englishmen who were not anxious to see despotism established. Parliament made war or peace at its pleasure. It was now obvious that not only had parliament become the chief power in the state, but that the house of commons was virtually parliament. To counteract this, the king adopted a plan recommended by Sir William Temple. He created a new council, or extended the privy council to 80 members, 15 of whom were to be the chief ministers, while the others were to be nobles or gentlemen, without office, but of wealth and consideration. It was expected that this council would satisfy all parties, but it satisfied nobody, and failed from the commencement of its existence. The old form was soon restored. A tory reaction made the calling of parliament together unnecessary in the last years of Charles II. His successor, James II., not content with an amount of power such as no other sovereign of his line had possessed, entered upon a course of action that plainly showed he had in view the total overthrow of the constitution both in church and state; and as his stanchest supporters had been churchmen, all parties in England were soon arrayed against him, except a few Catholics and a small portion of the dissenters. He had called a parliament immediately after his accession, and though it was the most servile body that had met for 80 years, and the king had said there were only 40 members of the house of commons whom he would not have named himself, he soon quarrelled with it. The ends which he had most at heart were, the repeal of the *habeas corpus* act, the establishment of a standing army, and the repeal of all laws that were directed against the Catholics. It so happened that these three things were precisely those which his own friends, the tories, were least inclined to grant. They were as much attached to the *habeas corpus* act as were the whigs; they associated the idea of a standing army with the military rule of Cromwell; and they saw ruin to the church of England in relief to the Catholics, and the one thing which they loved better than either monarch or monarchy was that church. For 3 years James carried on a warfare against the constitution, reviving the high commission court by his own act, and in defiance of acts of parliament, and in various other ways showing his utter contempt of all

restraint. The events of 1688-'9 removed him from the throne, set aside the direct line, and placed the constitution on a firm basis, on which it has rested without serious disturbance for 170 years. The government of parliament was then fairly acknowledged, and has never since been called in question. Even when George III., who in personal character had much resemblance to the Stuarts, and who would have been a king after their pattern if he could, resolved to rule as well as to reign, he sought to realize his design through the aid of parliament. Practically, too, parliamentary rule means the rule of the house of commons. The house of peers occupies a high place in the state. Within certain limits its power is by no means small. On general subjects it is at liberty to dissent from the commons but when the people are really determined upon carrying a political measure, the peers have to give way, no matter what may be their opinions as to its justice or expediency. A remarkable instance of this working of the English system was seen in 1832, when the reform bill was forced through the upper house, though it was notorious that a large majority of its members were opposed to the bill. In the reign of William and Mary, and of William III., many things were done to settle the principles of the constitution. The declaration of rights adopted by the convention parliament was confirmed by the regular parliament, soon after; and the act of settlement, passed in 1700, contains 8 additional articles, further limiting the power of the crown, and protecting popular freedom. The most important of these articles is the 7th, by which judges were to hold their seats during good behavior, and their salaries were to be ascertained and established. The first mutiny bill was passed in 1689, and has been renewed annually ever since, giving to parliament control of the sword. A triennial bill was passed in 1694, but septennial parliaments were established in 1717. As the law originally stood, the king could keep the parliament chosen immediately after his accession to the throne during the whole of his reign. The triennial act repealed this prerogative, and the septennial act confirmed that repeal, while it extended the time for which parliaments might endure. No parliament, however, since that time, has existed for 7 years; and though the motives of the men who carried through the septennial act were unquestionably of a party character, neither they, as ministers, nor parliament, were guilty of usurpation, the right of parliament to pass such an act resting on the same ground as its right to adopt any law. The laws relating to treason, to libel, and to toleration, passed in the years immediately following the revolution, and which became part of the constitution, were generally of a liberal character. After the accession of the house of Hanover, an attempt was made by a portion of the whigs to close the house of peers. George I. gave his consent to the introduction of a bill by which, after a few more creations, no additions were to be made to the peerage. For

the 16 elective peers of Scotland, 25 hereditary peers were to be substituted. Had this measure been successful, the worst consequences must have flowed from it. It did succeed in the house of peers, but the house of commons, under the lead of Walpole, threw it out. The government was strictly parliamentary down to the beginning of the reign of George III. That monarch attempted to rule parliament, and did not desist until he found that his best chance to accomplish his purpose would be through a union with that body. The demand for parliamentary reform commenced in the time of the American revolution, and was caused by the conviction that began to prevail among men of all classes that the existing abuses were owing to the vices of the electoral system. Had France remained quiet, the reform that was accomplished in 1832 would probably have been accomplished a generation earlier. The French revolution had the effect of delaying changes in England that were much demanded, as numerous members of the house of commons were returned by peers, or by rich individual commoners. The reform bill of 1832, though it changed the construction of the house of commons in some respects, did not lessen the power of that body, which is more influential now than it ever was before. The exclamation of Mr. Roebuck in 1858—"The crown! it is the house of commons!"—expresses in few words the precise character of the government of the British empire. The house of commons consists of 654 members, of whom 496 are returned from England and Wales, 105 from Ireland, and 53 from Scotland. The house of peers consists at present (1859) of about 450 members. Ireland sends 28 representative temporal peers, chosen for life, and 4 spiritual peers, who sit by rotation of sessions; and Scotland 16 representative peers, chosen for each parliament by the nobility of that country. The others are English temporal peers, with the exception of the 2 archbishops of York and Canterbury, and 24 bishops, who constitute the spiritual peerage of England. The house of peers is the supreme judicial court of the empire, exercising jurisdiction in civil causes upon appeals, and in criminal cases when brought before it by the house of commons by the process of impeachment. Peers can vote by proxy, but the privilege is not available when their house is in committee. Bills affecting the peerage must originate in the house of peers, and cannot be altered by the house of commons. When charged with treason or felony, a member of the upper house must be tried there; for lesser offences, by the common courts. The peer gives his verdict upon his honor, and answers in the same way to bills in chancery; but when a witness in any of the courts, he takes the usual oath. The sovereign, in theory, is almost as powerful as in early times, but in practice his power can hardly be said to exist. He can make war or peace, but the control of the purse and the sword by parliament

neutralizes that prerogative. The money to pay the salaries of the officers he appoints must be voted by parliament. He cannot alter the standard of the money which it is his privilege to coin. The appointments he makes are virtually made by parliament, the ministers being only a committee of members of that body, selected from it by its consent, and responsible to it. He is held to be incapable of doing wrong, and the ministers are responsible for all that is done in his name, which, whatever its justice in former times, is proper now, the king being capable of doing nothing, while his "advisers" do every thing. He is head of the church, but he cannot alter the state religion, and should he become a Catholic he would forfeit his crown. The privy council is appointed by the king, and is bound to advise him to the best judgment of the members. With the advice of this body the king can publish proclamations, provided they are of a legal character. The council can inquire into all offences against government, and commit offenders for trial. The judicial committee of the council is a court of appeal in cases of lunacy and idiocy, and in admiralty and plantation causes, in questions between colonies, and all questions of a kindred character. It has an appellate jurisdiction over all parts of the empire, except Great Britain and Ireland, in the last resort. The executive government is in the hands of the ministry, which consists of the leading men of the dominant party. This has not always been the custom, for though there have always been ministers, a ministry was not formed till after the revolution, of which event it was one of the consequences. The cabinet, though now formed from the ministry, and often confounded with it, is not identical with it, and is indeed much older than the ministry. It originated in the custom, which was inevitable, of intrusting power to some few of the king's ministers. In the reign of Charles I. this knot of ministers, or "junto," as they were called, were in the habit of holding meetings in the cabinet of the queen consort, Henrietta Maria, whence the name came to have its present meaning. The word cabal had the same meaning for a time, but the unpopularity of the cabal ministry, in the reign of Charles II., caused it to become so odious that it has never since been employed in a respectful sense. The cabinet, or rather the cabinet council, has never been recognized by the law, it has no legal existence now, the names of the persons who compose it are never officially published, and no record of its doings is kept. The difference between the cabinet and the ministry may, perhaps, be best stated by mentioning the composition of the existing English government. The ministry now consists of 25 persons, but the cabinet has only 18 members, viz.: the first lord of the treasury, chancellor of the exchequer, lord chancellor, president of the council, lord privy seal, secretaries of state for the home department, for foreign affairs, for the colonies

for war, for India, first lord of the admiralty, president of the board of trade, and president of the board of works. The secretaryship of India is of recent creation, dating only from 1858, when Victoria became queen of Hindostan, and the rule of the East India company over that country ceased. Among the ministers who are not of the cabinet are the commander of the forces, the postmaster-general, the lord lieutenant of Ireland, the chancellor of the duchy of Lancaster, the lord great chamberlain, the lord steward, and others. The post of prime minister, or premier, has generally been held by the first lord of the treasury since the accession of the house of Hanover. It was generally held by the lord treasurer in earlier times, but there has been no such officer since 1714. The office has ever since that date been in commission, and it was Sir Robert Walpole who first attached the place of prime minister to that of first lord commissioner of the treasury. Previously to that time a secretary of state had higher official rank than the head of the treasury; and after Walpole's fall, Lord Carteret (Earl Granville) was the principal man of the ministry to which he belonged, and was a secretary of state. It has sometimes happened that force of character has enabled a secretary of state to be premier in fact if not in name, as in the cases of the elder Pitt, Lord Castlereagh, and Mr. Canning; but the rule is, that the first lord of the treasury is premier. The two offices of first lord and chancellor of the exchequer have sometimes been held by the same person. The king can call a privy councillor to the cabinet, though he hold no office; and eminent men have sat in that body merely as cabinet councillors.—The principal authorities for the history of England are: the works of Turner, Palgrave, Kemble, and Lappenberg, on the Saxon times; Hallam's "Europe during the Middle Ages," and "Constitutional History of England;" Thierry's *Conquête de l'Angleterre par les Normands*; Miss Strickland's "Queens of England;" the works of Stephens, Creasy, and Raikes on the English constitution; the histories of England by Hume, Lingard, Knight, Macaulay, and Froude, the two last being devoted to special portions of that history.

ENGLAND, CHURCH OF, a Protestant episcopal organization established by law as the state church of England and Ireland. It is held by many that the gospel was preached in Britain in the 1st century by St. Paul himself during the period between his 1st and 2d imprisonments at Rome. It is at all events certain that the gospel was preached there, the church fully established, and the people generally, perhaps universally, converted to the faith, before the Saxon invasion. Of this early period in the history of the British church, however, we have much less information than could be desired. As early as 314, the island seems to have been divided into three ecclesiastical provinces, each with its metropolitan or archbishop, and of course with several bishops

under each. These three metropolitan sees were York, London, and another, the name of which has been matter of dispute, although it is generally admitted that it was a Welsh province with its seat at a place called Caerleon upon the U-ske, afterward at Menevia, now St. David's. At the council of Arles, in 314, the archbishops of these three sees were present as participants. There were also British bishops in the council of Sardica, in 347. About the middle of the 5th century the Saxons arrived in England, and in the course of the century following had not only gained the ascendancy there, but had near the close of the century, in 596, to a very great extent exterminated Christianity also. Augustin came as a missionary from Gregory, bishop of Rome, to convert the Saxons to Christianity. Efforts were also soon after made both from Ireland and Scotland to reconvert England to the faith which had been lost. The Saxon domination, however, had not extended throughout the west of England in any such way as altogether to abolish the Christian worship. The facts of history also indicate that there must have been a large portion of the Christian population even within the heptarchy itself still remaining, more especially among the females. By all these influences combined the Saxons were soon converted, and a general union of the believers effected. With a view of establishing uniformity of doctrine and discipline in the British church, Augustin held several conferences with the Welsh bishops, 6 or 7 in number, but with little success, as the latter refused to acknowledge the supremacy of the bishop of Rome or to conform to the Roman custom of celebrating Easter on the first Sunday of the paschal full moon. The British Christians, like those of the East, kept the festival on the 3d day after the 14th of the Jewish month Nisan, whatever day of the week that might be. They resembled the orientals also in the practice of baptismal immersion. It is claimed that these facts show that the bishop of Rome, up to the year 596, had possessed no authority over the church in England, and that the English or rather the British church was under no disability, censure, or disadvantage in consequence of its independence of the see of Rome. However, the influence of the advocates of Roman supremacy prevailed, and in the course of a few generations secured a conformity of the English Christians to the doctrines and usages of Rome. The establishment of monastic houses, exempt from local ecclesiastical jurisdiction and subject only and directly to the pope, greatly increased the Roman influence, and the Norman conquest had a like effect, although the pope found it necessary to oppose and resist the conqueror, as the king was disposed to subjugate the church to the royal prerogative and use it for purposes of state policy much further than it suited either Alexander II. or his successor Gregory VII. (Hildebrand) to allow. The controversies and contests between the conquered Saxons and the conquering Normans continued till they were settled by the accession of Henry I. and Matilda of Scotland,

and after that the quarrels between the king and his barons, ending in the resignation of his crown by John into the hands of the pope, to be received back by him and ever after to be held by an annual payment to the pope, served to increase the papal influence in England. From this period until the great reformation the ecclesiastical history of England, though marked by occasional disturbances and protests against the papal authority, has few features of general importance. But about the time when the preaching of Luther and his followers was arousing Germany, Henry VIII. undertook to set aside the pope's supremacy in England. Henry had married Catharine of Aragon, the widow of his deceased brother Arthur, but on falling in love with Anne Boleyn, he began to question the legality of his marriage. Anxious to prepare the way for a union with Anne, he requested the pope to declare his marriage with Catharine null *ab initio*, or to grant a divorce; but his request not being complied with, he referred the matter, by the advice of Thomas Cranmer, who now began to rise into notice, to his own clergy and universities, among whom, as well as at the seats of learning in foreign countries, he did not fail to find some who answered according to his wishes. Fortified by these opinions, Cranmer, who had been raised to the archbishopric of Canterbury, proclaimed the king's marriage with Catharine void, and confirmed his alliance with Anne Boleyn, whom he had privately wedded a few months before. The pope threatened Henry with the heaviest censures if he did not take back his legal wife, but Henry resolved to separate from the church of Rome rather than restrain his passion, and measures were at once taken to subject the clergy of the kingdom exclusively to the crown. A blow had already been struck at the old ecclesiastical system by the indictment of the English clergy in 1531 for supporting Wolsey in his powers as legate before receiving the royal sanction; and in the convocation held immediately after, in which a sum of money was voted to the crown by way of buying immunity from the consequences of conviction on this charge, the king was acknowledged to be "the one protector of the English church, its only and supreme lord, and, as far as might be by the law of Christ, its supreme head." By the same assemblage his marriage with Catharine was declared null, and in 1532 the parliament passed an act against paying to the pope the annates, or year's revenue of all bishoprics that fell vacant, which had formerly been paid to Rome as a tax on bulls issued to new prelates. At the same time it was ordained that no regard should be paid to censures which the pope might pass on account of this law, and that mass should be said and the sacraments administered as usual. In 1534 still more important measures were enacted. All payments made to the apostolic chamber, all bulls and dispensations were abolished; monasteries were subjected to royal government and visitation, and

exempted from all other; the right to summon convocations, approve or reject canons, and hear appeals from the bishops, was vested in the king alone, and sentence of deposition was passed upon Campeggio and Ghinucci, bishops of Salisbury and Worcester. Though now honored with the title of supreme head of the church on earth, Henry contemplated no change in the doctrines of the old church, and no setting up of a rival community. Indeed, it was not until 30 years or more after these steps that the Roman Catholics and the reformers were looked upon as separate bodies, or had a separate ministry and separate places of worship. Throughout Henry's reign much less was done toward a change in creed or ritual than during the short reign of his son, Edward VI. The fundamental principle avowed from the first to the last, however, was that, beside retaining the ministry and the creeds of the primitive church, they must in all points of doctrine and discipline also accept its authority. In this view the offices of devotion were expurgated of what were deemed errors and innovations, and translated into English (having been previously used in the Latin language), and brought together as a "Book of Common Prayer and Administration of the Sacraments." Homilies were prepared to be read in all the churches for the instruction of the people; the Bible also was translated, and not only read in public worship by the clergy, but copies were placed at the public expense in the churches, where they were accessible at all times, except during the hours of public service; and, finally, articles of religion were agreed upon, now known as the "XXXIX. Articles," and were published as indicative of the extent to which the church of England had departed from the belief and usages that had prevailed in England before the reformation, and still prevailed in the churches that were obedient to Rome on the continent. On the death of Edward VI., Mary, daughter of Henry VIII. and Catharine of Aragon, Henry's first wife, ascended the throne. She was a devout adherent of the papal authority, and set herself to secure its recognition in England. To prepare the way for the realization of her object, an important change was made in the house of bishops. Some were declared to be no bishops, because they were married men; some were deprived of their sees because they had been appointed to them only during the good pleasure of the king. Five were condemned and burned at the stake for the part they had taken in the reformation. Thus under Mary's rule the state again became Catholic, but in about 5 years she died, and was succeeded by Elizabeth, the daughter of Henry and Anne Boleyn, who brought back the reformed faith and usages. The bishops who had been deprived by Mary, and had saved their lives by fleeing from the country, were brought back, and either restored to their own sees or promoted to others that were vacant. More than

one-half the English bishoprics were either vacant when Elizabeth came to the throne, or presently became so without any act of hers. The filling of these sees gave her at once a majority in the councils of the church who sympathized with her, including among them of course those who had returned to occupy their old places. Several of Mary's bishops chose to retire rather than to conform. But in a short time things were restored in the English church to the condition in which they had been in the year previous to the death of Edward VI. During the latter part of the reign of Elizabeth, and throughout the reign of her successor, James, efforts were made to alter the articles of the church of England, so as to render them, if not unequivocally expressive of, yet entirely agreeable to, the Calvinistic theology. For this purpose the famous Lambeth articles were drawn up, and even the consent of Whitgift, archbishop of Canterbury, was obtained to their incorporation into the formularies and standards. The church, however, never gave any assent to those articles. And when, in 1628, King Charles issued his "Declaration concerning Religion," and required that the XXXIX. articles should be adhered to as the bond of union and standard of doctrine, he required that those articles should be received and held in their ordinary sense; "in the plain and full meaning thereof;" "in the literal and grammatical sense." The Calvinists complained bitterly that this was a restraint upon them, and a prohibition of their construction of the articles. We mention these facts to show that while the Roman Catholics had regarded the English church as being so far Protestant that they could not remain in its communion, the Calvinists also, whether those inclined to Presbyterianism or to Congregationalism, did not consider it possible to reconcile their theology with the XXXIX. articles in what was then understood to be their "accustomed, their plain and grammatical sense." After a season of trouble under the protectorate of Oliver and Richard Cromwell, from 1653 to 1660, the church was restored under Charles II. to its former position. The few bishops that remained, Juxon of London, Pierce of Bath and Wells, Skinner of Oxford, Warner of Rochester, Roberts of Bangor, Wren of Ely, Duppa of Salisbury, King of Chichester, and Frewen of Coventry and Lichfield, were restored, though not all to the sees they had held before, and the remaining sees again filled; the prayer book, lessons, and ritual came back into use as before the Puritan ascendancy. Even during the protectorate, the church, though oppressed and persecuted, had continued her ministrations; such men as Sanderson, Hackett, Bull, Fell, &c., remaining at their posts, and in the performance of their duties. Although they were not allowed to use the common prayer book either in public ministrations or private devotions, some of them had committed its contents to memory, and used its formularies throughout. On the restoration of Charles II. a conference

was held at the Savoy in London, to revise the "Book of Common Prayer and Administration of Sacraments," so as, if possible, to include all those who were inclined to dissent. Although the dissenters were represented by Baxter, the most learned, the mildest, and the most moderate of their number, no great result was accomplished. The dissenters, however, developed the fact that there was such a radical difference between the English church and themselves generally with regard to the fundamental conditions of salvation, regeneration, the means of grace, justification, &c., that no union could be effected between them, and no construction could fairly be put on the formularies of the church by which persons holding the views entertained by the dissenters, and denying the sacramental theory of the church, could consistently with honesty and self-respect remain in her communion. Charles II. was succeeded by his brother James II., a Roman Catholic. He sought first to secure for his own faith a free toleration in England, hoping, as it was supposed, to bring the English church again into conformity with that of Rome. The effort to do so was regarded as unconstitutional, and was one of the causes of the king's ejection from the throne. A portion of the bishops and clergy who had been foremost to resist his efforts to Romanize the church, stood by him when the dissenters and others sought to place William of Orange on the throne in his stead. They considered themselves bound in conscience to preserve the purity and integrity of the church, and equally bound by their oath of allegiance to be faithful to his inherited right to the throne, and to that of his son James (Francis Edward). Hence they refused the oath of allegiance to William, and became known in history as the non-jurors. Beside adhering to the constitutional rights of James and his son, called the pretender, they were also the persons who were known as the high churchmen, in opposition to the low churchmen, who were so called because of the sympathy in their general views with the dissenters and non-churchmen. This state of things caused the high churchmen to be no favorites with William and his political advisers and friends; a feeling which has had its effect ever since. In 1717, during the reign of George I. the church, in consequence of its attempt to enforce its discipline upon Hoadley, bishop of Bangor, and a favorite with the king, was forbidden to hold sessions of its convocations, or to enter upon any legislative or ecclesiastical business of a corporate character. The convocation, however, continued to go through the form of an annual meeting, though it was invariably prorogued before it could proceed to business, and it is only within a very few years that its legitimate functions have been partially restored. It was undeniable that Hoadley had not only denied the divine origin and obligation of the episcopal polity of the church, but he had also denied other of the fundamental articles of the faith as taught and held by the English church,

that for example with regard to the divinity of Christ. The effects of this ascendancy of what has been called Erastianism in the church were soon felt. The high places in the church came to be sought by persons who had far more desire for the income and respectability of position which they afforded than for the work which they called for—more anxious in fact to benefit themselves by a good living than the souls of men by hard work and spiritual counsel and guidance. A general apathy in religious matters ensued—broken by such disturbances as the Wesleyan or Methodist movement, and the rise of the evangelicals of the school of Newton, Toplady, and Simeon, occasioned—until about 1830, when a movement was contemplated and actually proposed, which it was earnestly believed and seriously feared would sweep away all that was distinctive of the church as between itself and the Protestant dissenters. This fear and the prospect which it contemplated led to the publication of the “Oxford Tracts,” by members of the university of Oxford, and that recurrence to the principles of the church as held and practised before the revolution of 1688, which has been characterized as “Puseyism;” principles which had for a time nearly died out with the non-jurors.—In the foregoing review of the history of the church of England we have aimed at the twofold purpose of (1) presenting an outline of its history, and (2) showing from this history both its ecclesiastical and its doctrinal position. Ecclesiastically, it claims to be the perpetuation and legitimate heir and representative of the church founded in England before the Saxon invasion, before the Norman conquest, before the reformation. The English claim that they had a perfect right to reject the papal authority, inasmuch as (1) it was not given by any direct divine institution or appointment witnessed or testified to in the Holy Scriptures; (2) its claims from the first were in contravention of the most sacred canons of the universal church; and (3) the discontinuance of any submission that there may have previously been to the see of Rome had at the time of the reformation become indispensable to the purity of religion, the best interests of the church, and the spiritual welfare of the people; so that if it were formally and in external appearance a schism (which they of course do not admit), it was nevertheless not only justifiable, but necessary. Doctrinally the church of England claims to be based on the Holy Scriptures, as interpreted in the Apostles’ and other ancient creeds of the church that have been universally received, and to have kept herself aloof from all the modern systems of faith, whether of Calvin, or Luther, or Arminius, leaving her members free to enjoy their own opinions on all points not represented in the Scriptures as necessary to the soul’s health, and refusing to be narrowed down to any other creed or creeds than those of the apostles and the primitive church. She claims also to have retained all that is essential to church organization in her episcopate, and in her liturgy

to have not only a wise and judicious compend of doctrine and devotion, but also one of the most effectual of all possible conservative safeguards for the faith once delivered to the saints. The characteristic tenets of the church of England, beside the fundamental doctrines of the Trinity and redemption through the all-sufficient atonement once made for all by the death of Christ on the cross, are a regeneration or spiritual birth in baptism, in which the baptized becomes a member of the church, and a growth in grace by the use of the sacraments and ministrations of the church duly administered and duly received, made efficacious by the Word of divine truth and the gracious influences of the Holy Ghost, freely given to all who duly seek and faithfully use them. The condition of man after the fall is such that he can do nothing acceptable to God without preventing grace; good works, though pleasing to Heaven, have no power to put away sin; works of supererogation, over and above God’s commandments, cannot be taught without arrogance and impiety; the church has power to decree rites or ceremonies, and to decide matters of faith; the Roman Catholic doctrines of purgatory, invocation of saints, and respect to relics and images, are rejected; clergymen are allowed to marry; and communion is to be given in both kinds. The number of sacraments is two, baptism and the Lord’s supper. Three clerical orders are recognized, bishops, priests, and deacons, the first deriving their office in direct succession from the apostles by episcopal consecration, and the others receiving ordination at the hands of a bishop. Those of the second order are entitled archdeacons, deans, rectors, vicars, or curates, according to their functions. A reader is a layman licensed by the bishop to read in a church or chapel where there is no clergyman. Parson signifies a clergyman in possession of a parochial church.—The church of England is divided into 2 provinces, Canterbury and York, with an archbishop in each, and under these 26 bishops. The dioceses are much too large, and a gradual reduction in their size by divisions is being effected. Beside these are 82 bishops in the English colonial dependencies, with a number of clergy amounting in all, at home and in the colonies, to about 20,000. The dioceses of Ripon and Manchester, in the province of York, were created in the reigns of William IV. and Victoria; and the sees of Gloucester and Bristol, in the province of Canterbury, have been united. The bishop of Sodor and Man does not sit in parliament. The others constitute the spiritual peerage of England, and are in theory appointed by the crown, in fact by the ministry. Next to the archbishops rank the bishops of London, Durham, and Winchester, and the others take rank according to the date of their consecration. The revenues of the church of England are often represented as an endowment from the state—a tax levied and collected by parliament for the support of an institution for

which many of the people have no choice or regard; but this is a mistake. At the time of the reformation nearly if not quite one-fifth of all the property in the realm, both real and personal, was in the possession of the church and ecclesiastical persons, and held by them for their own personal support, and for purposes of charity and religion. Much of this consisted in real estate which had been given in trust to the church, or to specific purposes in the church; much of it consisted in tithes which had been granted the church, and were thus an encumbrance on the property as it passed from the owner who granted those tithes to his heirs and posterity. Of the property then in possession of the church, a large part was taken into the royal exchequer, a large part was given to royal favorites, and enriched many a penniless family, thus placing them among the magnates of the land. The estates of the duke of Bedford are of this kind. But the present revenues of the English church are only what remain to it of the property which the church held under the old state of things; and the only agency of the state or the parliament in the matter may be stated in general terms to be merely the enforcement of the rights of property which originated as above described. It is indeed true that in consequence of the great changes in the value of property in so many years there is a great disparity in the incomes of the clergy. Other causes have also contributed to this result; and within a few years past a movement has been set on foot to remedy this defect. An ecclesiastical commission has been appointed, and some approach made toward converting the income of the church into a common fund, with a distribution to be made according to the wants and necessities of each office. The average income of the clergy, notwithstanding the large incomes of some of the sees, as Winchester, Canterbury, and London, is less than £400 per annum; and for about three-fourths of them its average is less than £100. In a few cases it is only £10; in others it reaches as high as £7,300. The total income of the church is about £5,500,000, and is derived from tithes, lands, church rates, pew rents, Easter offerings, and surplice fees. In 1851 the tithes were converted into rent charges, payable in money. From Queen Anne's bounty (so called because that sovereign granted the produce of first fruits and tenths, formerly sent to the pope, but from the reformation to her time paid to the monarch, "for the augmentation of the maintenance of the poor clergy") there is annually paid £14,000 to the holders of small livings; and similar disposition is made of other moneys from ecclesiastical sources. The number of places of worship of the established church in England, Wales, and the islands of the British seas, in 1851, was 15,131, having sittings for 5,619,946 persons.—In the United States the adherents to the doctrines of the Church of England are called Protestant Episcopalians. (See EPISCOPAL CHURCH IN THE UNITED STATES.)

ENGLAND, LANGUAGE and LITERATURE OF. The English is eminently a composite language, made up of contributions from other languages. It derives its origin from the Celtic, the Latin, the Anglo-Saxon, the Danish, the Norman French, and some others. For the investigation of this subject there are two modes. One of these is linguistic, and is more strictly philological. The affinities and diversities of the various words in the language furnish what may be called the internal evidence of the several sources from which the vocabulary and the constructions were derived. The other mode of research, which is ethnological, and which furnishes the external evidence from the history and migration of nations, often conducts to the same conclusions with the linguistic method. When, for instance, we hear of a stream called *Wans-beck-water*, and know that each of the 3 words of which the whole word is made up signifies "water," the first in the Celtic, the second in the German, and the third in the English, we recognize 3 changes of inhabitants, to whom the former name successively lost its significance. This is internal evidence. We also know from history that the Celts, the Saxons, and the English have successively occupied the territory where that stream is found. This is external evidence. Both kinds of evidence in this case conduct us toward the conclusion that the Celts and Saxons contributed materials to the formation of the language.—*The Celtic element.* In the English vocabulary are found basket, from the Celtic *basgona*; cobble, from *ceubal*; nattock, from *matog*; pail, from *pacol*; and other words of a like derivation. Moreover, a large part of the names of the mountains, lakes, and rivers in the British isles are significant only in some Celtic dialect. The Celts were very early inhabitants of Britain. They emigrated from central Asia in the early ages of the world toward the west. They were probably pressed onward by other tribes, until they reached the Atlantic ocean and passed over the English channel into Great Britain. Their descendants are still found in Wales and in Cornwall, as well as in Ireland, in the highlands of Scotland, in the isle of Man, and in Brittany in France. Of Celtic words the English language has few; of Celtic constructions, none.—*The Latin element.* In the English vocabulary are found street, from the Latin *strata*; master, from *magister*; state, from *status*; April, from *Aprilis*; and many other words of a like derivation. The Romans under Julius Cæsar invaded England, 55 B. C., and afterward under Agricola completed the conquest of the country. Roman law and magistracies were everywhere established, and the Christian religion was introduced by those who spoke the Latin language. It should, however, be stated that the Latin words in the language were not, for the most part, introduced during the 500 years that the Romans had possession of Britain, but afterward, while Anglo-Saxons bore sway, or later still. A large number of Latin words were in-

introduced by monks and learned men, relating to theology and science in general. Words of Latin origin constitute a very important part of the language, whether introduced directly from the Latin or through the Norman French. The following is the development of the Latin portion of the language: 1, stem verbs, or roots, as *bib*, *carp*, *cede*, *urge*; 2, stem adjectives, as *bland*, *brute*, *brev* (short); 3, stem substantives, as *arc*, *barb*; 4, primary derivatives, as *final*, *factor*; 5, secondary derivatives, as *valuable*, *moderate*; 6, derivative words with prefixes, as *abode*, *allude*; 7, compound words, such as *leopard*.—*The Anglo-Saxon element*. Whether we take into view the number or the sorts of words, the Anglo-Saxon is less an element than the mother tongue of the English. In the English language there are as many as 23,000 words of Anglo-Saxon origin. About $\frac{1}{3}$ of the words in actual use are from this source. The names of the greater part of the objects of nature, as *sun*, *moon*, *day*; all those words which express bodily action, as *to stand*, *to stagger*; all those words which are expressive of the earliest and dearest connections, as *father*, *mother*, *brother*, *sister*, are Anglo-Saxon. Most of those objects about which the practical reason is employed in common life, nearly all English pronouns, a large proportion of the language of invective, humor, satire, and colloquial pleasantry, are Anglo-Saxon. English grammar is almost exclusively occupied with what is of Anglo-Saxon origin. The English genitive, the general mode of forming the plural of nouns, and the terminations by which we express the comparative and the superlative of adjectives (*er* and *est*), the inflections of the pronouns and of the verbs, and the most frequent termination of adverbs (*ly*), are all Anglo-Saxon; so are the auxiliary verbs. In fact, the Anglo-Saxon imparted so much of itself to the language, that the proximate origin of the English language is to be sought in Germany, and its remote origin is to be sought in central Asia, where was spoken the primitive tongue which may be regarded as the parent of the affiliated Indo-European languages, spoken by the successive tribes which migrated westward into Europe. The natural development of the Anglo-Saxon portion of our language has been nearly as follows: 1, instinctive forms and pronominal elements, as *ah*, *oh*; 2, stem words or roots, as *bend*, *swim*; 3, stem nouns, as *blank*, *band*; 4, reduplicate forms, as *chit-chat*, *sing-song*; 5, primary derivatives, as *chatter*, *toilsome*; 6, secondary derivatives, as *carefully*, *tiresomeness*; 7, words with prefixes, as *arise*, *forbid*; 8, compound words, as *god-man*, *pick-purse*; 9, disguised compounds and derivatives, as *daisy*, *not*.—*The Danish element*. Many hundreds of words in the language, especially those used as the names of places, are Danish, introduced during the incursions and occupation of England by the Danes. A portion of these words are indeed provincial, being confined to the northern and north-eastern counties of

England, the regions most exposed to Danish visitation.—*The Anglo-Norman element*. An etymological analysis of the language shows that the Anglo-Norman element enters very largely into its composition. This element, which is composed of the Celtic, the Latin, and the Scandinavian, was first introduced (1066) by the Normans, under William the Conqueror. Norman French was spoken by the superior classes of society in England from the conquest to the time of Edward III. (1327). The laws of the realm, the proceedings in parliament and in courts of justice, were in that language. In the 13th century, during the progressive mixture of the two races, a literature sprang up in which the two languages were more or less mixed together. In the 14th century the Anglo-Saxon principle seemed to have gained the upper hand. In the 15th century the Anglo-Norman element seemed to be gaining the preponderance; but the proportions still continued to vary until it became fixed in the age of Queen Elizabeth. Words were generally adopted into the common language from the Anglo-Norman or the Anglo-Saxon, according as the objects or ideas expressed by those words belonged more exclusively to one race or the other. Thus the names of common articles of dress are Anglo-Saxon, as *shirt*, *breeches*, *hose*, *shoes*, *hat*, *cloak*; but other articles subject to changes of fashion are Anglo-Norman, as *gown*, *coat*, *boots*, *mantle*, *cap*, *bonnet*. The word *house*, a common residence, is Anglo-Saxon; but *palaces*, *castles*, *manors*, and *mansions* are Anglo-Norman. The names *ox*, *colt*, *sheep*, *pig*, *boar*, are Anglo-Saxon, because that part of the population were engaged in tending those animals while they were living; but *beef*, *veal*, *mutton*, *pork*, *venison*, are Anglo-Norman names, because that part of the population were accustomed to eat their flesh when they were killed. The natural development of the Anglo-Norman or Romanic portion of the language is nearly as follows: 1, verbal roots in English, as *boil*, *cay* in decay, *ceive* in conceive, *pound*, *touch*; 2, stem adjectives, as *chaste*, *clear*; 3, stem substantives, as *beast*, &c.; 4, derivative words with suffixes, as *flourish*, *authorize*, *volunteer*, *arabesque*, *plumage*, *journal*, *service*, *fashion*; 5, derivative words with prefixes, as *atouch*, *antechamber*, *countermark*; 6, Romanic compounds, as *portfolio*, *wardrobe*; 7, disguised Romanic words, as *biscuit*, *bachelor*, *proctor*, *curfew*. The common statement is, that Anglo-Saxon was converted into English: 1, by contracting and otherwise modifying the pronunciation and orthography of words; 2, by omitting many inflections, especially of the noun, and consequently making more use of articles and auxiliaries; 3, by the introduction of French derivatives; 4, by using less inversion and ellipsis, especially in poetry.—Beside the languages already mentioned which have contributed to the composition of the English, several others, and especially the Greek, should also be mentioned: 1, Greek verbal roots, as *arch*, in archetype, *graph*, in graphic; 2, Greek

stem adjectives, as *kal*, beautiful, in calligraphy, *kryph*, "hidden," in apocrypha; 3, Greek stem substantives, as *rhomb*, *chord*; 4, Greek derivative words with suffixes, as *poet*, *chrism*; 5, secondary derivatives, as *Baptist*, *Christian*; 6, Greek derivative words with prefixes, as *apoplexy*, *catarrh*, *catastrophe*; 7, Greek compounds, as *democracy*, *pedagogue*. There are also in the language Hebrew words, as *mana*, a gum, *jasper*, a precious stone, *sabbath*; Spanish words, *cortes*, *don*; Italian words, as *stanza*, *piazza*; Russian words, as *czar*, *ukase*; Persian words, as *bazaar*, *shah*; Arabic words, as *alcemie*, *gazelle*; Chinese words, as *chop*, *hyson*; and Indian words, as *homing*, *moccason*. "We Britons," says Harris, "in our time, have been remarkable borrowers, as our multiform language may sufficiently show. Our terms in polite literature prove this, that they come from Greece; our terms in music and painting, that these come from Italy; our phrases in cookery and war, that we learned these from the French; and our phrases in navigation, that we were taught by the Flemings and Low Dutch."—From its composite character, the English is naturally copious in its vocabulary and phrases. There are large classes of words derived from the Norman or the classical languages which are, in common parlance, synonymous with words derived from the Anglo-Saxon, so that a writer may have his choice whether to use the Romanic or the Teutonic element, a choice of great value to him who has the taste to preserve the delicate differences of words as well as their agreement. General terms are derived from the Latin; those that denote the special varieties of objects, qualities, and modes of action, are derived from the Anglo-Saxon. Thus, *color*, a general term, is Latin; but *white*, *black*, *green*, particular terms, are Anglo-Saxon. It has been correctly remarked that "Latin furnishes the elegant, the Saxon the common expression, as *bad odor* and *stench*, or *perspiration* and *sweat*." In looking through the several stages of the language, namely, the Saxon, the semi-Saxon, the old English, the middle English, the modern English, we are struck with the constant death of old words, and the constant birth of new ones that come in to fill their places. In the early periods this was due to the successive irruptions of foreigners, who in introducing their own language necessarily expelled a portion of the vernacular whose place it took. "Great verity," says Camden, "was the glory of the English tongue before the Norman conquest, in this, that the old English could express most aptly all the conceits of the mind in their own tongue without borrowing from any." "The alteration in our tongue hath been brought about by the entrance of strangers, as Danes, Normans, and others who have swarmed hither; by traffic, for new words as well as new works have always come in; by the tyrant Time, which altereth all things under heaven; by use, which swayeth most and hath an absolute command in

words." Another cause of the mutations we have referred to is that the pursuits of the English people have been multiform beyond those of any European nation, and the language has correspondingly changed. Lexicographers too, in their zeal to introduce new words, to the neglect of old ones, have contributed to the changes by recording the one class and by omitting the other. In Halliwell's "Dictionary of Archaic and Provincial Words" there are more than 50,000 words not recorded in modern dictionaries.—For further information on this subject the reader may consult Grimm's *Deutsche Grammatik* (4 vols., Göttingen, 1819-'37); Guest's "History of English Rhythms" (London, 1838); Rask's "Anglo-Saxon Grammar," translated by Thorpe (London); Bopp's "Comparative Grammar," translated by Eastwick (3 vols. 8vo., London); Trench's "English, Past and Present" (New York ed., 1855); Gould Brown's "Grammar of English Grammars" (New York, 1857); Latham's "Hand-Book of the English Language" (New York ed., 1857); Fowler's "English Language in its Elements and Forms" (New York, 1859).—ENGLISH LITERATURE was preceded in the British islands by compositions in the Cymric or ancient British, Anglo-Saxon, Anglo-Norman or early French, and Latin languages. There are extant a few Cymric metrical pieces which date probably from the 6th century; they are the songs of the celebrated Welsh bards Aneurin, Taliesin, Llywarch-Hen, and Merdlin, the sage as well as poet, whom succeeding centuries transfigured into the enchanter Merlin. To Gildas, a brother of Aneurin, is attributed a Latin prose tract, *De Excidio et Conquestu Britannia*, which, if genuine, is the earliest historical work produced in Britain that has been preserved. The personages mentioned in these eldest British songs and annals, as Arthur, Merlin, Kay, and Gawain, played prominent parts in romantic literature a few centuries later, and even to this day afford favorite themes for the poets. During the Anglo-Saxon period both a vernacular and a Latin literature were cultivated, their most flourishing era being the 8th century, the age of Alcuin, Aldhelm, Bede, and Ceolfrid. The monasteries of England and Ireland sent forth many scholars of European celebrity for learning, and Alcuin and Erigena served especially to associate these countries with the continent in liberal studies. The alliterative, unrhyming versification of the Anglo-Saxons continued to be employed in some of the early English poems. The Norman conquest, however, almost abolished the use of the Anglo-Saxon language in writing, and for more than a century the prevalent literature of England was either in Latin or in Anglo-Norman. Lanfranc and Anselm, who were attracted from France by the conqueror, and became successively archbishops of Canterbury, originated or revived the scholastic philosophy, the treatises on which were in Latin, and several of the most eminent later doctors of which, as Alexander Hales, Duns Scotus, and William

Occam, were of British birth. Roger Bacon is especially remarkable for his acquaintance with Hebrew and Arabic literature, and quotes from 10 of the most highly reputed Saracen authors. In connection with him may be mentioned Michael Scotus, the wizard of the northern ballads, whose writings were celebrated throughout Europe. The scholastic writers of the 12th century prided themselves on their epistolary style, and many collections of their letters have been preserved, which are among the most valuable illustrations of the public and private history of the time. Those letters begin with Lanfranc, were very numerous in the reign of Henry II., and the most interesting of them in a literary point of view are those of John of Salisbury and Peter of Blois. Latin poems abounded throughout the 12th century, and those of Laurence of Durham, John of Salisbury, John de Hauteville, Nigellus Wirker, and Alexander Neckham, contain passages of nearly classic elegance. The most ambitious attempts were by Joseph of Exeter, who wrote two epics in heroic measure. A new style of versification, in which rhymes took the place of the ancient metres, was introduced, and soon attained an attractive energy and sprightliness. It was brought to perfection in the satirical poems attributed to Walter Mapes, which exhibit excellent sense and humor amid bacchanalian jovialities. In his *Confessio Goliæ* is found the famous drinking song beginning *Meum est propositum in taberna mori*. This kind of poetry became extremely popular, and flourished long after the style of the more serious Latin authors had become hopelessly debased. But the most important Latin works during the Norman period were the chronicles or histories, all of them by ecclesiastics. The chronicle of Odericus Vitalis (died in 1182) was the first in which history was made an object of laborious research; that of William of Malmesbury is the most elegant; and that of Geoffrey of Monmouth exerted the greatest influence on subsequent literature, becoming one of the cornerstones of romantic fiction. It narrated Welsh and Armorican traditions of British history from Brutus, an imaginary son of Æneas, to Cadwallader in the 7th century. Ingulphus, Henry of Huntingdon, Giraldus Cambrensis, Roger de Hoveden, Matthew Paris, and Jocelin de Brakelonde, are perhaps the other most important names in the long catalogue of monkish chroniclers. The earliest Anglo-Norman compositions extant are supposed to belong to the first part of the 12th century. In the reigns of Stephen and Henry II. a school of poets was formed devoted to versifying history in that language, the three great masters of which were Wace, Gaimar, and Benoit de Sainte-Maur. Wace translated Geoffrey's British history into Anglo-Norman verse, under the title of the *Roman de Brut*, which extends to over 15,000 lines; and also wrote the *Roman de Rou*, giving the legends concerning Rollo the Norman. Gaimar made a metrical continuation of the narrative of Geoffrey to the Norman pe-

riod; and Benoit composed a romance of the history of Troy, which upheld the claims of several of the western nations to a Trojan origin. The cycle of romances relating to Arthur and the round table were prevalent in England from the 11th to the 14th century. They were in the French language, but several of them, as the "Merlin," "Lancelot," "Queste du Saint Graal," and "Mort d'Arthur," were written by Englishmen for the English court and nobles. Some writers have maintained also that the lays of Marie and the romances concerning Charlemagne and his paladins appeared in England earlier than in France. The original source of these fictions, and of romantic poetry in Europe, is attributed by Bishop Percy to the Scandinavians through the Normans, by Warton to the Arabians through the Moors of Spain, and by Ellis and Turner to the inhabitants of Armorica or Brittany.—During this prevalence of Latin and Anglo-Norman literature the Anglo-Saxon language had been confined to the conquered race, but the Saxon chronicles had been carried on in obscure monasteries by various annalists to the year 1154. About 50 years later, when the two races began to unite in one nation, a work appeared written in Anglo-Saxon so much modified by French that it is usually accounted the beginning of English literature. This was Layamon's translation of Wace's *Roman de Brut*, which was followed in the 13th century by a multitude of translations from Latin and Anglo-Norman. The older chronicles were more or less closely followed in the English metrical pieces of Robert of Gloucester and Robert Manning, a monk of Bourne. The Anglo-Norman romances were reproduced in the English metrical romances of "Sir Tristrem," "Sir Perceval of Galles," "Ywayne and Gawayne," "Havelok the Dane," "King Horn," "Cœur de Lion," "King Alesander," "Morte Arthure," "Sir Guy," the "King of Tars," and many others. "Sir Tristrem," which is one of the oldest of them, was attributed by Sir Walter Scott, on grounds now generally admitted to be unsatisfactory, to the Scottish poet Thomas the Rhymer. The body of Latin tales entitled *Gesta Romanorum*, perhaps of German origin, was now and continued much later to be a source of materials for English authors. The first original English poet, who left the beaten track of translation from chronicles, romances, and legends of the saints, was Laurence Minot (about 1350), the author of some short ballad-like poems on the victories of the English armies in the reign of Edward III. Richard Rolle, a hermit of Hampole, produced about the same time a moral poem entitled the "Pricke of Conscience." The most remarkable production before the age of Chaucer is the "Vision of Piers Ploughman," ascribed to Robert Langlande. It is in alliterative verse, without rhyme, abounds in allegorical personifications, and is a satire on the vices of the times and especially of the ecclesiastics. It has passages of humor and extraor-

stem adjectives, as *kāl*, beautiful, in calligraphy, *kryph*, "hidden," in apocrypha; 3, Greek stem substantives, as *rhomb*, *chord*; 4, Greek derivative words with suffixes, as *poet*, *chrism*; 5, secondary derivatives, as *Baptist*, *Christian*; 6, Greek derivative words with prefixes, as *apoplexy*, *catarrh*, *catastrophe*; 7, Greek compounds, as *democracy*, *pedagogue*. There are also in the language Hebrew words, as *mana*, a gum, *jasper*, a precious stone, *sabbath*; Spanish words, *cortez*, *don*; Italian words, as *stanza*, *piazza*; Russian words, as *czar*, *ukase*; Persian words, as *bazaar*, *shah*; Arabic words, as *alcemic*, *gizelle*; Chinese words, as *chop*, *lyson*; and Indian words, as *homing*, *moccason*. "We Britons," says Harris, "in our time, have been remarkable borrowers, as our multiform language may sufficiently show. Our terms in polite literature prove this, that they come from Greece; our terms in music and painting, that these come from Italy; our phrases in cookery and war, that we learned these from the French; and our phrases in navigation, that we were taught by the Flemings and Low Dutch."—From its composite character, the English is naturally copious in its vocabulary and phrases. There are large classes of words derived from the Norman or the classical languages which are, in common parlance, synonymous with words derived from the Anglo-Saxon, so that a writer may have his choice whether to use the Romanic or the Teutonic element, a choice of great value to him who has the taste to preserve the delicate differences of words as well as their agreement. General terms are derived from the Latin; those that denote the special varieties of objects, qualities, and modes of action, are derived from the Anglo-Saxon. Thus, *color*, a general term, is Latin; but *white*, *black*, *green*, particular terms, are Anglo-Saxon. It has been correctly remarked that "Latin furnishes the elegant, the Saxon the common expression, as *bad odor* and *stench*, or *perspiration* and *sweat*." This was Layamon's translation of Wace's *Roman de Brut*, which was followed in the 13th century by a multitude of translations from Latin and Anglo-Norman. The older chronicles were more or less closely followed in the English metrical pieces of Robert of Gloucester and Robert Manning, a monk of Bourne. The Anglo-Norman romances were reproduced in the English metrical romances of "Sir Tristrem," "Sir Perceval of Galles," "Ywayne and Gawayne," "Havelok the Dane," "King Horn," "Cœur de Lion," "King Alesander," "Morte d'Arthur," "Sir Guy," the "King of Tars," and many others. "Sir Tristrem," which is one of the oldest of them, was attributed by Sir Walter Scott, on grounds now generally admitted to be unsatisfactory, to the Scottish poet Thomas the Rhymer. The body of Latin tales entitled *Gesta Romanorum*, perhaps of German origin, was now and continued much later to be a source of materials for English authors. The first original English poet, who left the beaten track of translation from chronicles, romances, and legends of the saints, was Laurence Minot (about 1350), the author of some short ballad-like poems on the victories of the English armies in the reign of Edward III. Richard Rolle, a hermit of Hampole, produced about the same time a moral poem entitled the "Pricke of Conscience." The most remarkable production before the age of Chaucer is the "Vision of Piers Ploughman," ascribed to Robert Langlande. It is in alliterative verse, without rhyme, abounds in allegorical personifications, and is a satire on the vices of the times and especially of the ecclesiastics. It has passages of humor and extraor-

earliest fountain of pathos and harmony in English dramatic poetry; and Thomas Lodge, who was associated with Greene in writing the "Looking-Glass for London and England," a strange performance, in which the prophecy of Jonah against Nineveh is applied to the city of London. All of these abound in bombast and pedantic classical allusions. A more potent spirit was Christopher Marlowe (1565-'93), who, throwing off the shackles of rhyme, gave to blank verse an easy modulation and rhythm, and produced scenes and passages of wonderful beauty and grandeur amid rant and buffooneries. His most admired plays are the "Jew of Malta," "Edward II.," and the "Life and Death of Dr. Faustus," and the last best illustrates the "fine madness" of his character. An awful melancholy pervades the fiend Mephistopheles, more impressive than the malignant mirth ascribed to him by Goethe. Marlowe was the immediate precursor of William Shakespeare (1564-1616), the greatest name in English literature, whom a poet has styled "the genius of the British isles," and who stands at the head of the romantic or Christian drama. A comparison of his works with those of his contemporaries proves his superiority as much in judgment and taste as in creative power, for a large proportion of his plays are more regular than any other prior to the close of the civil wars. The rules of the classical dramatic art were not then in vogue; the French neo-classical drama had not been originated; and though Shakespeare violated the ancient unities of time and place, he observed almost universally the unity of feeling and of interest, which is perhaps the only unity possible in any drama that embraces the wide scope, the fine materials, and the passionate intensity of Christian thought. The soundest criticism has vindicated for him the character of a profound artist as well as a great and luxuriant genius, and his peculiar excellences appear in the marvellous variety and verisimilitude of his personages, in the skill with which opposite characters are grouped and the finest and most diversified threads woven into a harmonious web, and in the completeness with which the entire action as well as the several characters are worked out, minute features and particulars being poetically conceived with reference to the universal system of things. Shakespeare's plays are 34 in number (the authorship of some of which, however, is disputed), and are usually divided into tragedies, comedies, and histories. Since the beginning of the present century their supremacy has attained unqualified and intelligent recognition. A friend of Shakespeare and his associate in the Mermaid, the oldest of clubs, was Ben Jonson (1574-1637), one of the most familiar of the names of the old dramatists. He had scholarly acquaintance with the classics, and labored to make the laws of the ancients authoritative in English dramatic art. He is the author of two tragedies, "Catiline" and "Sejanus," and of numerous comedies and masques, the best of

which are the "Alchemist," "Volpone, or the Fox," and the "Silent Woman." They are full of solid materials, in a stately, eloquent, but often intolerably pedantic style, and seem to have been produced slowly and upon deliberation, the wit, fancy, and satire being severely elaborated. Dryden admired him as the pattern of elaborate writing. His poetical character appears in its most pleasing aspect in the lyrical verses with which his masques are varied and enlivened, especially in the pastoral drama of the "Sad Shepherd," which display an admirable taste and feeling, and have all the charms of song. Jonson may have aimed at an audience of men of sense and knowledge, but Beaumont and Fletcher wrote for men of fashion and the world. Of the 52 plays published under their joint names, Beaumont may have had a part in only 17. They are keen, vivacious, and often elegant, but slight and superficial in comparison with Shakespeare's and Jonson's; the songs scattered through them are, however, among the most subtly beautiful in the language. The dramas of George Chapman (1557-1634), the translator of Homer, contain "more thinking" than those of most of his contemporaries: they have many passages of striking grandeur, are in a lofty and extravagant style, and their contemplations on the nature of man and the world leave impressions favorable to moral excellence. The "Fortunatus" and "Honest Whore" of Thomas Decker have graceful and genial passages, and the "Duchess of Malfy" and "White Devil" of John Webster are full of horrors cleverly managed, and have been esteemed among the most striking tragic productions of this period. The modern reputation of Thomas Middleton rests chiefly on his "Witch," which may have suggested to Shakespeare the supernatural scenery in "Macbeth;" and the coarse plays of John Marston abound in murders, ghosts, and scornful satire. Of the tragedies of Philip Massinger (1584-1640), the "Duke of Milan" and the "Fatal Dowry" are among the best; and of his comedies, the "Picture," the "Bondman," and "A Very Woman." His "New Way to Pay Old Debts" still keeps the stage, for which it is indebted to its effective character of Sir Giles Overreach. His style has an easy and majestic flow, and "he is read," says Lamb, "with composure and placid delight." John Ford (1586-1639) preferred dark vices and the deepest distress for subjects, and his works make a sad and abiding impression, having, as Hallam remarks, the power over tears. He seems to have taken an intellectual pleasure in revolving the various possibilities and revenges of sin, and the best of his plays bears the title of the "Broken Heart." Thomas Heywood, an indefatigable and popular dramatist, wrote "beautiful prose put into heroic metre." James Shirley (died in 1667) is the last of this circle of dramatists, and the least remarkable either for merits or faults. Under the commonwealth, and the ascendancy of the Puritans, who had always been at feud with the wits, the theatres were closed, and the players flogged.

At the restoration, the drama was revived under the influence of French rules, and of a strong anti-Puritan reaction, and the larger part of the plays for 40 years are declared by Macaulay to be a disgrace to the English language and the national character. A shamelessness, as inelegant as it was immoral, was the common characteristic of the drama. To ridicule and degrade virtue, sincerity, and prudence, was the business of the stage, which it followed with an impudence so unblushing as to have the charm of diabolical *naïveté*. Blank verse was for a time displaced by rhyme, but the tragic authors soon returned to the former, and the comic sank to familiar prose. The best tragedies of the period are the "Orphan" and "Venice Preserved" of Thomas Otway (1651-'85); and though the former displeases the delicacy of our age, the latter has been more frequently represented than any other tragedy after those of Shakespeare. The genius of the unhappy poet appears especially in pathetic delineations of passion and misery, and few heroines have been so highly honored with the tribute of tears as Belvidera in "Venice Preserved." John Dryden, who was rivalled by none of his contemporaries as a satirical, didactic, and lyric poet, abused his rare gifts to attain dramatic success, the faculty for which nature had denied him. His "Don Sebastian," "Spanish Friar," and "All for Love," are the best of numerous tragedies and comedies, the absurd bombast and ribaldry of which have made them almost forgotten notwithstanding their surprising incidents, stately declamation, and harmonious numbers. The "Fatal Discovery" of Thomas Southerne, the "Jane Shore" of Nicholas Rowe, the "Fatal Curiosity" of William Lillo, the "Mourning Bride" of Congreve, and the "Rival Queen" of Nathaniel Lee, may also be mentioned among successful tragedies. The proper representatives of the comedy of this period are William Wycherly, William Congreve, George Farquhar, and Sir John Vanbrugh, and among their profligate plays the most popular were the "Plain Dealer" and the "Country Wife," "Love for Love" and the "Way of the World," the "Beaux Stratagem" and the "Trip to the Jubilee," and the "Provoked Husband" and the "Provoked Wife." Mrs. Aphra Behn, Thomas Shadwell, and Sir George Etherege also deserve mention among those who made the stage as immoral as their talents permitted. The "Careless Husband" and other plays of Colley Cibber, and the "Busy Body" and "Bold Stroke for a Wife" of Mrs. Centlivre, connect the period of the restoration with that of Anne. Among the non-dramatic poets of the period from Elizabeth to Anne, Edmund Spenser (1558-'99), John Milton (1608-1674), and John Dryden (1631-1700), successively held preëminence. The unfinished product of Spenser's imagination, the "Faëry Queen," is a monument of the contemplative and retrospective thought of the Elizabethan age, an age as philosophical as it was adventurous. The moral allegory,

which had been among the earliest fruits of modern literature, was brought to perfection in this poem, which presents exquisitely beautiful pictures of an ideal chivalry in a land of enchantment. Yet the descriptions of an imaginary world, though luxuriant and circumstantial, often lack the interest of real life, and affect us as remote and abstract speculations. Its peculiar stanza, to which his name has been given, a modification of the Italian *ottava rima*, with the addition of an Alexandrine to each verse to give a full and sweeping close, was an innovation in the art of poetry, and has since been adopted by Shenstone in his "Schoolmistress," Beattie in his "Minstrel," Byron in his "Childe Harold," Thomson in his "Castle of Indolence," Shelley in his "Revolt of Islam," and by many other English poets. The "Shepherd's Kalendar," and the hymns to "Love" and "Beauty," are among the finest of Spenser's minor pieces, the last revealing his sympathy with Platonic doctrines. Nearly contemporary with the "Faëry Queen" were the songs and sonnets of Sir Philip Sidney; the "Saint Peter's Complaint" and "Mary Magdalene's Funeral Tears" of Robert Southwell; the "Civil Wars," "Complaint of Rosamond," and numerous minor pieces of Samuel Daniel, of a pensive character, and in remarkably pure style; the "Baron's Wars" and the "Polyolbion" of Michael Drayton, the former a metrical chronicle, and the latter an immense piece of metrical topography, which contains also striking national legends and ingenious allegorical and mythological inventions; the few and brief poems of Sir Henry Wotton; the "Orchestra" and the "Soul of Man and the Immortality thereof" of Sir John Davies, the latter a happily condensed piece of metaphysical reasoning; the satires of Bishop Hall, the earliest in the language except the "Steele Glass" of Gascoyne; the satires, elegies, and various lyrics of John Donne, which are rather metrical problems than poems, strongly manifesting the metaphysical tendency then common in poetry, but which reveal a subtle intellect and fruitful fancy, though obscure in thought, rugged in versification, and full of as bad affectations and conceits as are to be found in the century; the poems of the brothers Phineas and Giles Fletcher, the principal of which are the "Purple Island," an allegorical description of the human soul and body, and "Christ's Victory and Triumph," which is one of the most beautiful of religious compositions; and the sacred poems of the country parson, George Herbert. In Scotland, Alexander Scott and Sir Richard Maitland wrote brief poems; Alexander Montgomery, the "Cherry and the Sloe;" Alexander Hume, the "Day Estival;" King James VI., the "Essayes of a Prentice in the Divine Art of Poesie;" the earl of Stirling, his "Recreations with the Muses;" Sir Robert Aytoun, his few songs; and William Drummond, one of the most distinguished poets of his time, his sonnets, madrigals, and larger pieces. Marlowe's

the music is sweeter afterward;" and at the close of his survey he predicted that "the third period of time will far surpass that of the Grecian and Roman learning." His style, usually sententious and somewhat stiff, became more imaginative, richer, and softer with his increasing years; but though his fancy was of the brightest, he allowed to it no other office than that of ministering to reason. His application of thought to purposes of utility and progress, with a view to the practical restitution of man to the sovereignty of nature, has entered as a characteristic element into the public mind of England. His "Essays" are among the masterpieces of English prose, and are equally eminent for power of expression and for compact and solid wisdom. Contemporary productions were the "Arcadia" and the "Defence of Poesy" of Sir Philip Sidney, the former of which was universally read and admired; the "History of the World" of Sir Walter Raleigh, written in the Tower; the "Chronicle of England" and "Survey of London" of John Stow; the chronicles of Raphael Holinshed; the collection of voyages by Richard Hakluyt; the "Purchas his Pilgrims" of Samuel Purchas; the "Relation of a Journey," &c., of George Sandys; the "Epistolæ Ho-Eliañæ" of James Howell; the "History of the Turks" of Richard Knolles; and the sermons of Bishop Andrews and Dr. Donne, mosaics of quaintness, quotation, wisdom, folly, subtlety, and ecstasy. The writings of John Lilly produced a marked effect on much of the Elizabethan literature. His "Euphues," a dull story of a young Athenian, in a smooth style, full of affected conceits and recondite similes, was the model after which wits and gallants formed their conversation and writing. The ladies of the court were among his pupils, and Blount (1632) remarks that the beauty who could not "parley Euphuisme" was as little regarded as one that could not speak French. Under James I. was produced the translation of the Bible which has been generally in authority from that time. Between Bacon and Locke, the most acute of English metaphysicians was Thomas Hobbes (1588-1679), whose political theories are collected in his "Leviathan." His style is uniformly excellent, a merit which belongs to no one of his predecessors. Among his contemporaries were the sceptical philosopher Lord Herbert of Cherbury, who wrote also a history of the reign of Henry VIII.; the antiquaries William Camden, Sir Henry Spelman, Sir Robert Cotton, and John Speed; John Selden, the author of a "Treatise on Titles of Honor," and whose admirable "Table Talk" was published after his death; the chronologist Archbishop Usher; William Chillingworth, whose "Religion of Protestants" is a model of perspicuous reasoning; Peter Heylin, a wit and divine, the author of "Microcosmus"; John Hales, a preacher and controversialist; John Gauden, the supposed author of the famous "Eikon Basilike," which professed to emanate from the pen of Charles I.; and the two most eloquent of the old English di-

viners, Joseph Hall (1574-1656), and Jeremy Taylor (1618-1667), whose works are monuments of their own abilities and of the pedantic tastes of the age. The "Contemplations" of Hall are superior to any of the writings of Taylor in continuity of thought, but the latter has perhaps had no equal in the pulpit in the splendor of his imagination, and is often called the Shakespeare of divines. The most curious works of the time are the "Anatomy of Melancholy" of Robert Burton (1576-1640), composed largely of apt and learned quotations from rare authors, constantly intermingled with the writer's own thoughts, and which exhibits in every part great spirit and power, and has the charm of a full and vigorous style; and the "Religio Medici," "Urn Burial," and other works of Sir Thomas Browne (1605-1682), whose popularity has revived in our own day—elaborately quaint compositions, fascinating from their pensiveness akin to melancholy, their paradoxes, and their occasional subtlety and imaginative brilliancy. Under the head of essays or sketches may be classed the "Gull's Hornbook" of the dramatist Decker, the "Characters" of Sir Thomas Overbury, the "Resolves" of Owen Feltham, the "Microcosmography" attributed to Bishop Earle, the miscellaneous pieces of Sir Henry Wotton, and the "Discourses by way of Essays" of Cowley. The last are written in a placid and perspicuous style, very unlike the affected obscurities of his poems, and may be reckoned among the earliest models of good writing in English prose. John Locke (1632-1704) is the author of treatises on civil government, education, and the reasonableness of Christianity, which diffused a spirit of liberty and toleration in opinion and government; but his most important work is the "Essay on the Human Understanding," which soon became the acknowledged code of English philosophy, and displays and inculcates a careful, tentative observation of intellectual habits. It helped to convert metaphysics from scholastic problems into practical and clearly intelligible analyses, but its indefiniteness in the use of the phrase "ideas of reflection" has left the essential character and tendency of the Lockean system in dispute between sensationalists and idealists. Two writers who at this time deviated from the track which English speculation has chiefly followed, and in whom Platonic tendencies predominated, were Ralph Cudworth, the author of the "Intellectual System of the Universe," and Henry More, the author of the "Mystery of Godliness," the "Mystery of Iniquity," and other works which were once very popular. The sermons of Barrow, South, and Tillotson were respectively esteemed for strength, wit, and rational unction, but the last have retained least of their former popularity. To this period belong most of the prose writings of Milton, which test the power of the language in vigorous and lofty declamation, the *Origines Sacrae* of Stillingfleet, the theological treatises of Sherlock, the "Exposition of the Creed" of Pearson, the "Exposi-

tion of the XXXIX. Articles" of Bishop Burnet, the "Saint's Everlasting Rest" and other works of Baxter, the expository works of Leighton, Owen, and Henry, and the writings of the Quakers George Fox, Robert Barclay, William Penn, and Thomas Ellwood. This age of divines and comic dramatists was also distinguished for its devotion to practical science under the guidance of the spirit of Bacon, and chemistry and physics became as fashionable as wine and love, and as much respected as defences of the Trinity. Instances of this tendency are the "Discovery of a New World" and the other so called "mathematical works" of Bishop Wilkins, the "History of the Royal Society" of Sprat, the "Sacred Theory of the Earth" of Thomas Burnet, the "Sylva" and "Terra" of Evelyn, the "Observations" and the "Wisdom of God Manifested in the Works of Creation" of John Ray, and above all others, the "Considerations on the Usefulness of Experimental Philosophy," and other works, philosophical and religious, of Robert Boyle, and the *Philosophiæ Naturalis Principia Mathematica* of Sir Isaac Newton. Among antiquarian works were the *Monasticon Anglicanum* of Sir William Dugdale, the *Athenæ Oxonienses* of Anthony à Wood, the history of the order of the garter by Elias Ashmole, the "Miscellanies" of John Aubrey, and the *Fœdera* of Thomas Rymer, who also wrote a curious treatise on tragedy, in which Shakespeare is criticized according to certain stately notions derived from the ancients. Works of high literary interest are the "Worthies of England" of Thomas Fuller, one of the strangest books in the world, a melange of oddity, sagacity, and humor, in a pithy style; the "History of the Rebellion" of Lord Clarendon, which, in spite of its deliberate partiality, is admirable for its portraiture of character and its animated narrative; the "Observations on the United Provinces of the Netherlands" of Sir William Temple; the histories of the reformation and of his own times by Gilbert Burnet; the "Pilgrim's Progress" of John Bunyan, a specimen of homely English, the fruit of a lively and powerful imagination cultivated only by the study of the Scriptures; and the half poetical "Complete Angler" of Izaak Walton, who also wrote some pleasing biographies. Minor works were the translations and political pamphlets of Sir Robert L'Estrange, the "Contemplations" of Sir Matthew Hale, the "Essays" on ancient and modern learning by Temple, and the "Reflections" in answer to them by Wotton. Tom D'Urfey and Tom Brown, "merry fellows," the last of the wits of the restoration, wrote comic and licentious compositions in prose and verse. The "Short View," &c., of Jeremy Collier was the beginning of a controversy between him and the comic dramatists which resulted in the reformation of the theatre.—With the reign of Anne (1702-'14) begins a new era in English composition, when the affluence of the older literature gave way to correctness. The rules of the art were better understood, style

was cleared of its redundancies, and wit refined from its alloy. The writers of the Elizabethan period, in an age of stupendous changes, on the confines between barbarism and refinement, had dealt with the original passions and principles of human nature, and had found their illustrations in the pageantry of past institutions and in dreams of the future. As the English advanced to the character of a polished nation, losing the bluntness and heartiness of their older manners, their literature also became less wild and grand in its romance and more regular in its outlines, the suggestions of genius being moulded by the rules of taste. As enriched and refined by the writers of the reign of Anne, which is often called the Augustan age of the literature, the language was almost finally formed. The fashions and frivolities of elegant and artificial life became the themes of poets and essayists, and while the highest regions of poetry and speculation were abandoned, books were no longer confined to the learned or curious, but were gradually spread among all classes. Men of letters now first became known in England as a distinct class in society. To bring philosophy out of closets and libraries, schools and colleges, and to make it dwell in clubs and assemblies, at tea tables, and in coffee houses, was the object which Steele proposed to himself. That school of poetry which may be traced to the adoption of French rules under Charles II., which acquired stability from the transcendent powers of Dryden, and which was now perfected by Alexander Pope (1688-1744), retained its ascendancy nearly through the 18th century. The follies of his feeble copyists have reacted injuriously upon the fame of the great master of the school. For half a century the notion prevailed that whoever deviated from the standard of Pope was worthy only to figure in the "Dunciad;" but somewhat later it became common to deny to him poetic genius, imagination, and versatility, and to decry his wit, epigrammatic force, and faultless numbers, by confounding them with the imitations of the dunces who had caught something of his metre but nothing of his spirit. His correctness was branded as the badge of unimaginative and artificial verse, and may almost be numbered among the lost arts. Yet Campbell and Byron were zealous to do him justice, and the latter compared the poetry of the 18th century to the Parthenon, and that of his own times to a Turkish mosque, and boasts that though he assisted in rearing the gaudy and fantastic structure, he had never defaced nor depreciated the monuments of a purer taste. The vigor of conception and point of expression which distinguish the "Essay on Man," the "Rape of the Lock," the "Epistle from Eloisa to Abelard," the "Satires," and the "Dunciad," will at least vindicate for them the highest rank in a peculiar and admirable class of compositions. His "Iliad" and "Odyssey," though un-Homeric, are valuable additions to English literature. The finest contemporary poetical productions were the "Letter from Italy," the

"Campaign," and the "Cato" of Addison, the octo-syllabic satires and occasional pieces of Swift, the "Shepherd's Week, in Six Pastorals" of Gay, the "Hermit" and the "Night Piece on Death" of Parnell, and the "Gentle Shepherd" of the Scotch poet Allan Ramsay. The names of Prior, Tickell, Garth, Blackmore, Ambrose Philips, Somerville, and Anne countess of Winchelsea, also belong here. It is remarked by Wordsworth that between the publication of "Paradise Lost" and of the "Seasons" of James Thomson (1700-1748), with the exception of the "Windsor Forest" of Pope and a passage in the "Nocturnal Reverie" of the countess of Winchelsea, not a single new image of external nature was produced in poetry. The "Seasons" are almost the only memorial which the age has left of poetical sympathy with natural scenery. It was original as well in style as in substance, for its blank verse has an easy flow peculiar to itself. The "Castle of Indolence" is a successful imitation of the manner of Spenser, and has great and peculiar beauty. The "Night Thoughts" of Edward Young (1681-1765) is also in effective blank verse, dissertational rather than simply poetical, in a sustained imaginative and epigrammatic style. The "Grave" of Robert Blair and the hymns of Watts are serious and devotional compositions of the same time. Through the "Bastard" of Richard Savage, the "London" and "Vanity of Human Wishes" of Dr. Johnson, the eclogues and odes of William Collins, the "Pleasures of the Imagination" of Mark Akenside, the odes and the "Elegy" of Thomas Gray, the "Deserted Village" and the "Traveller" of Oliver Goldsmith, the "Minstrel" of James Beattie, the "Botanic Garden" of Erasmus Darwin, and the "Task" of William Cowper, the line of English poetry was continued almost to the commencement of the present century. Johnson and Goldsmith both belonged to the school of Pope; but their poetry has distinctive characteristics, that of Johnson being marked especially by vigor and strong sense, and that of Goldsmith by sweetness and grace. The "Ode on the Passions" and several other pieces of Collins are masterpieces in their kind, and especially remarkable for the pictorial effects produced by the personification of abstract qualities. Collins and Gray were the two finest lyric poets of the century, and Gray's "Elegy written in a Country Churchyard" and his Pindaric ode of "The Bard" are exquisite examples of finished art and poetical vigor. Cowper was the precursor of the regeneration of poetry, and, abandoning the stock images and metrical sing-song with which art and fashion had been described, he produced pictures of English life and scenery marked by a simplicity, freedom, and freshness which anticipated the dawn of a new period. Among the productions of minor poets of the 18th century are the "Grongar Hill" of John Dyer, the "Schoolmistress" of Shenstone, the "Colin and Lucy" of Tickell, the ballad-like "William and

Margaret" of Mallet, the Scotch songs of Ross, the "Mary's Dream" of Lowe, the "Auld Robin Gray" of Lady Anne Barnard, the "Tullochgorum" of Skinner, the "Tweedside" of Crawford, the various poems of Ferguson, the odes, and the epitaph on his wife, of Mason, the odes of Smollett, the "Art of Preserving Health" of Armstrong, the "Cumnor Hall" and the translation of the "Lusiad" of Mickle, the "Braes of Yarrow" of Hamilton, the elegies of Hammond, the "Careless Content" of Byrom, the "Country Justice" of Langhorne, the "Lawyer's Farewell to his Muse" of Blackstone, the "Shipwreck" of Falconer, the "Actor" of Robert Lloyd, the "Rosciad" and other satires of Charles Churchill, the brief poems of Thomas and Joseph Warton, the "Leonidas" and "Athenais" of Glover, the short lyrics and translations of Sir William Jones, the "Chameleon" of Merrick, the pastorals of John Cunningham, the "New Bath Guide" of Anstey, and the "Triumphs of Temper" and other works of Hayley, who, though the feeblest of the imitators of Pope, was once considered a great poet. In the latter half of the 18th century also Macpherson produced the pieces which he ascribed to Ossian, Chatterton wrote the poems which he ascribed to Rowley, and Percy collected many old songs and ballads in his "Reliques of English Poetry."—The English drama of the 18th century bore the impress of the neo-classical school reigning in France, and presented a complete separation of tragedy and comedy. The "Cato" of Addison, the "Elfrida" of Mason, and the "Irene" of Dr. Johnson, though once acted, are rather dramatic poems than plays. The "Sophonisba" and 4 other tragedies of Thomson are the undramatic attempts of a descriptive poet. More successful tragedies were the "Revenge" of Young, the "Barbarossa" of Brown, the "Gamester" of Moore, the "Elvira" of Mallet, and the "Douglas" of Home, the most effective of them all. In this period were produced the finest examples of the legitimate English comedy, written usually in prose, and exhibiting refinement of sentiment and wit. The forerunners of the comedies of Goldsmith and Sheridan were the "Conscious Lovers" of Steele, the "Suspicious Husband" of Hoadley, the "Jealous Wife" of the elder Colman, the "Clandestine Marriage" of Colman and Garrick, the "Way to Keep Him" of Murphy, the "False Delicacy" of Kelly, and the "West Indian" of Cumberland. Goldsmith's "She Stoops to Conquer" has every requisite for making an audience merry, and, according to Davies, "revived fancy, wit, gayety, humor, incident, and character, in place of sentiment and moral preachment." The "School for Scandal," the "Rivals," and the "Critic" of Sheridan are distinguished for epigrammatic witticisms, insight into social weaknesses, and ingeniously contrived whimsical situations; and the first is in many respects superior to any other comedy of modern times. The "Lying Valet" and "Miss in her Teens" of Garrick, the "Belle's

Stratagem" of Mrs. Cowley, the "Tom Thumb" of Fielding, the "Man of the World" of Macklin, the "High Life Below Stairs" of Townley, the "Devil to Pay" of Coffey, and especially the 20 farcical plays of Foote, were the best and most popular comic productions of this epoch.—The prose authors of the 18th century may nearly all be classed as essayists, philosophers, historians, divines, and novelists. Periodical papers containing news had existed in England from the time of the civil war, but the "Tatler," planned by Sir Richard Steele (1671–1729), was the first periodical designed to have literary merit and to discuss the features and "smaller morals" of society. It appeared 3 times a week, extended to 271 numbers from April 12, 1709, to Jan. 2, 1711, and each number contained some lively sketch, anecdote, or humorous discussion, and was sold for a penny. It was succeeded by the "Spectator," which appeared every week-day morning in the shape of a single leaf from March 1, 1711, to Dec. 1712; after a suspension it reappeared 3 times a week in 1714, and extended to 635 numbers. The "Guardian" was begun in 1714, but became political, and ceased after the 176th number. Steele was the principal contributor to the "Tatler" and "Guardian," and Addison to the "Spectator," but papers were also furnished by Swift, Pope, Berkeley, Budgell, Tickell, and Hughes. The essays, especially those of Addison, were often models of grace, delicacy, and amenity, and were highly influential in correcting and refining the tone of society. Numerous works similar in form and purpose appeared later in the century, of which the only ones that have retained their place in literature are the "Rambler," written almost wholly by Dr. Johnson, the "Adventurer," by Hawkesworth, Johnson, and Warton, the "Idler," chiefly by Dr. Johnson, the "World," by Moore, Horace Walpole, Lyttleton, and the earl of Chesterfield, the "Connoisseur," by Colman and Thornton, which received also a few essays from the poet Cowper, and the "Mirror" and the "Lounger," both published in Scotland, and supported by a band of literary lawyers, among whom were Mackenzie, Craig, Cullen, Bannatyne, Hailes, Abercromby, and Tytler. The letters of Lady Mary Wortley Montagu, who was an associate of the wits of the time, are models of an easy and elegant epistolary style. The two chief philosophical writers of the early part of the century are Bishop Berkeley and the earl of Shaftesbury, and the "Minute Philosopher" of the former is the happiest imitation in English of the dialogues of Plato. The style of his other metaphysical treatises is singularly animated and imaginative. In his "Theory of Vision" he advanced novel and ingenious views on optics which are now universally adopted. His doctrine of idealism, the object of which was to prove that nothing existed but God and ideas in the mind, marked an era in English philosophy, and gave rise to a protracted discussion which has hardly yet ceased. He was personally one

of the most esteemed men of his time, and exerted great influence in favor of religion and in giving popularity and fashion to metaphysical studies. The "Characteristics" of the earl of Shaftesbury, once greatly admired for their moral and religious sentiments, and their elegant though affected diction, are now little read. He suggested the theory of a "moral sense," which was adopted and illustrated by subsequent Scotch philosophers. The levity with which he sometimes alluded to Christian doctrines greatly impaired his influence. A similar levity is even more apparent in the letters of Lord Bolingbroke, the philosophical works of a restless factionist, who was long considered a master of the art of written eloquence. The current philosophy of the 18th century was strongly affected by sceptical tendencies, whose influence pervaded the literature of England as of nearly every European country. Bishop Butler, in the preface of his "Analogy," declared that many persons then took it for granted that Christianity was no longer a subject of inquiry, but had at length been discovered to be fictitious; and in 1753 it was stated in the house of commons to be the fashion for a man to declare himself of no religion. This spirit of scepticism especially infested the department of historical composition, which at this time received a great impulse. A malevolence toward Christianity is the chief fault of the "Decline and Fall of the Roman Empire," by Edward Gibbon (1737–'94), the greatest historical work in the English language. No other historian has ever drawn his materials from a wider variety of sources, or written at once with so much erudition and genius. The history of England by David Hume, and of Scotland and of the reign of Charles V. by William Robertson, have retained their reputation for ease and elegance of style, though later researches have shown their neglect of accuracy. Less important historical and biographical writers were Echard, Strype, Smollett, Tytler, Ferguson, Middleton, Watson, Lyttleton, Russell, and Jortin. The principal philosophical and critical works after those of Berkeley and Shaftesbury were Hutcheson's "Inquiry into Beauty and Virtue" and "System of Moral Philosophy," Hume's "Essays" and "Treatise on Human Nature," Adam Smith's "Theory of Moral Sentiments," Reid's "Inquiry into the Human Mind" and "Essays on the Intellectual Powers," Beattie's "Dissertations, Moral and Critical," Hartley's "Observations on Man, his Frame, his Duty, and his Expectations," Price's "Review of the Principal Questions and Difficulties in Morals," Ferguson's "History of Civil Society" and "Institutes of Moral Philosophy," Tucker's "Light of Nature Pursued," Priestley's "Matter and Spirit," Lord Kames's "Essays on the Principles of Morality and Natural Religion" and "Elements of Criticism," Hugh Blair's "Rhetorical Lectures," and George Campbell's "Philosophy of Rhetoric." The critical and controversial writings of Bentley and Atterbury belong to the early part of this period. The theological writ-

ers of greatest influence were Clarke, Lowth, Hoadley, Leslie, Whiston, Doddridge, Butler, Warburton, Wesley, Lardner, Farmer, and Le land. Dr. Johnson, Goldsmith, and Burke, surpassed all others as miscellaneous writers, and probably Dr. Johnson exerted by his conversation and his pen a greater influence upon the literature and tone of thought of his age than any other individual. It was his wit and eloquence, argument and learning, says Lord Mahon, which first stemmed the tide of infidelity, and turned the literary current in favor of revealed religion. It was said by Burke that he appears far greater in Boswell's pages than in his own, and the reason is that he conversed with admirable simplicity and plainness, but in his writings adopted an elaborately vicious and ponderous style—a style which, according to his own favorite choice of terms, would be described as grandiose, magniloquent, and sesquipedalian. In the 18th century the novel assumed nearly the form and character which have since made it a leading department of literature. The "Arcadia" of Sir Philip Sidney had been followed by a large number of chivalrously heroic and courtly pastoral romances, many of them translations and adaptations, as Johnson's once famous "Seven Champions of Christendom," and in the 17th century, the "Man in the Moon" of Francis Godwin. After the restoration the most popular novels of the continent were translated, but of English original fictions, the "Parthenissa" of Lord Orrery and the tales of Mrs. Behn and Mrs. Manley are all that are now remembered even by the antiquary. Daniel Defoe (1661–1731) first gave to English fiction a simple, direct, matter of fact, and human interest, and the verisimilitude of "Robinson Crusoe" and his other novels has never been excelled. The "Tale of a Tub" and "Gulliver's Travels" by Swift, the "History of John Bull" by Arbuthnot, and the "Memoirs of the Extraordinary Life, Works, and Discoveries of Martinus Scriblerus," are satires in the form of fictitious narratives. All the writings of Swift are admirable for their vigor and humor. Under his successors the novel became more complex and artistic, embraced greater varieties of character and diversities of treatment, and pictured the artificial refinements and distinctions of society, the contrasts of temper and manners, and the complicated and conflicting relations of life. The "Joseph Andrews," "Tom Jones," and "Amelia" of Fielding, and the "Pamela," "Clarissa Harlowe," and "Sir Charles Grandison" of Richardson, were published near the middle of the century. Fielding claimed for his great work, "Tom Jones," the dignity of a comic epopee. Its plot, which involves wonderfully diversified characters and adventures, is contrived with almost perfect art, and it portrays the especial features of real life in England, with keenness, coarseness, an easy humor, and a buoyant affluence of practical knowledge. Richardson is one of the most powerful, tragic, and tedious of novelists, and his voluminous works obtained almost unexampled pop-

ularity in England and on the continent. He and Fielding were embodiments respectively of the idealistic and the realistic tendency, and each entertained great contempt for the writings of the other. The "Peregrine Pickle," "Humphry Clinker," and other novels of Smollett are distinguished for coarse, comic incidents and broad humor, and the "Tristram Shandy" and "Sentimental Journey" of Sterne contain masterly touches of character, passages and episodes sparkling with wit and fancy, and also much melodramatic pathos and sentimentality. Three works of fiction contributed especially to refine the public taste and the style of novels: the "Rasselas" of Dr. Johnson, a philosophical essay in the garb of an oriental tale, the "Vicar of Wakefield" of Goldsmith, a picture of English rural life remarkable for kindliness and taste, and the "Castle of Otranto" of Horace Walpole, a striking Gothic and chivalric romance. In 1771 Mackenzie produced the interesting character of the "Man of Feeling," and a few years later appeared Miss Burney's "Evelina," "the first tale written by a woman, and purporting to be a picture of life and manners, that lived or deserved to live," and which showed that both the vulgar and fashionable life of London might be delineated with lively skill, and with broad comic humor, without a line to offend a delicate taste. This and her second novel, "Cecilia," are especially esteemed for their characterizations.—With the French revolution begins a new period in English literature. Again, as in the age of Elizabeth, great civil and religious changes were agitated; old habits and feelings were to be set aside, old manners to pass into oblivion; and out of the ruins of venerable institutions political theorists were seeking to rear the structure of a new social order. Amid bloodshed and confusion, in the conflict between traditions and hopes, men were forced to speculate on the very elements of human nature and destiny. The commotion of the times marked a change of scene in the drama of European civilization, and, though it did not shake the constitution of England, it stirred the mind of the country in every department, and led to deeper moods of thought and to larger sympathies. The revival of poetry had already been prepared by Cowper. A greater influence, probably, was exerted by Robert Burns (1759–'96), "a miracle of human nature," whose "Tam O'Shanter," "Hallowe'en," and "Cotter's Saturday Night," were as indigenous to the soil of Scotland as the thistle, and displayed a freshness of humor, pathos, force, and beauty, which made them esteemed alike by peasants and scholars, and that union of the morally sublime with the extrinsically humble which soon became an aim and principle with Wordsworth. Yet his influence did not extend at once to England, where Cowper was still rivalled in popularity by Darwin and Hayley, who pompously versified prosaic subjects, and made steam engines boil and flowers woo and win each other

in song. Connected with these was the Della Crusean school of affected rhymesters, prominent among whom were Anna Seward, called the swan of Lichfield, Mrs. Piozzi (formerly Mrs. Thrale), Mrs. Robinson, Greathead, Merry, Weston, and Parsons, who were exposed and savagely ridiculed by Gifford in his "Baviad" and "Meviad." Matthew Gregory Lewis was the leader of a romantic school, both of poetry and prose fiction, abounding in *diablerie* and all manner of extramundane machinery, to which the perturbed temper of the times gave a momentary success. His verses were reflected in some of the most powerful contemporary prose, and exerted an influence on the early productions of Scott, Southey, and Coleridge, but were demolished by the "Rovers" of Canning and Frere, who also ridiculed Darwin's "Loves of the Plants" by a burlesque entitled the "Loves of the Triangles." William Wordsworth (1770-1850), esteemed by many the greatest poet of his century, devoted his life with singleness and firmness of purpose to the art of poetry. It was the solemn business of his being, the object of all his thought, observation, reading, and experience; and the ultimate goal which he proposed to himself was the composition of a vast philosophical poem, treating of man, nature, and society. His aim was to renovate and refresh literature by bringing back poetry from over-refinements of sentiment and rhetoric to truth and nature; and he began by composing lyrical ballads on the humblest subjects in language such as was "really used by men." Readers, long familiar with poems on learned themes or marked by polished sentimentalities, marvelled at his bald topics and colloquial platitudes as literary eccentricities, and could hardly tell whether they were designed to be comic or serious; and his first collection, which was certainly a melange of good and bad, contained passages of simple nature and unsophisticated pathos as grotesque as the fripperies of Della Crusean art. Yet the simplicity of feeling, the truthfulness of delineation, the comprehensive spirit of humanity, and the union of deep and subtle thought with sensibility, which marked his better pieces, attracted by degrees a circle of enthusiastic admirers. The works of no other poet have been so exclusively the product of personal experience and retrospection. His intense and unwearied delight in the shapes and appearances of rural and mountain scenery was constantly supplied by the wild region where he dwelt, and where every natural feature received the coloring of his own imagination; and his poems are made up of didactic philosophizing founded on analyses of his own thoughts, or of characters and scenes which illustrate the elements and phases of his own character, with a running commentary of natural phenomena, revealing always that harmonious and almost blended activity of intellect and passion which distinguishes him as a philosophical poet. In striking contrast with Wordsworth, who stead-

fastly pursued his purposes, was the rhapsodical and indolent Samuel Taylor Coleridge, whose finest pieces, as "Christabel" and the "Ancient Mariner," were produced early in life, and are unsurpassed in the language as strong, wild, and musical sallies of pure imagination. The faultless rhythm of "Christabel," accentual instead of syllabic, was the acknowledged model of Scott's "Lay of the Last Minstrel." As a philosopher and critic he has inspired rather than instructed many followers to rise to higher standpoints than those of Locke, Paley, and Lord Kames. Robert Southey when a schoolboy conceived the design of exhibiting in narrative poems the grandest forms of mythology that ever obtained among men, and his "Thalaba" and "Curse of Kehama," founded on Arab and Hindoo legends, were the partial fulfilments of his plan, and display through a charming diction extensive learning and brilliant imagination. The irregular, unrhyming verse of "Thalaba" he described as the "Arabesque ornament of an Arabian tale." Southey was the most diligent and indomitable of literary men, and in almost every department of prose and poetry has left monuments of his talent and erudition. A new tendency appeared in the poems of Sir Walter Scott, who combined the refinements of modern poetry with the spirit and materials of border minstrelsy and of the early metrical romances. He adopted in his principal poems the octosyllabic measure, which had been generally used by the old romancers. From 1805 to 1812, when the first cantos of "Childe Harold" appeared, Scott was the most popular British poet; but he retreated to prose fiction, as the genius of Byron began to display its strength. The historical ballad which he brought into vogue has since been successfully cultivated by Lockhart, Macaulay, and Aytoun. Prof. Wilson, after producing a few poems marked especially by delicacy of sentiment and vigor of description, applied himself chiefly to prose literature, criticism, and philosophy. The celebrity of Lord Byron was unrivalled during his brief and impetuous career; and perhaps no other man, dying at 37, ever wrote so much that was remarkable for intellectual power and intensity of passion. A new phase of the poetic mind appeared in Keats, the greatest of British poets that have died in early youth, who gave promise not only by his profusion of conceptions of beauty and grandeur, but also by the progress which he rapidly made in bringing his genius under the control of judgment. He had an instinct for choice words, which were in themselves pictures or ideas, and his example has affected especially the forms of poetical expression, to which he gave a refined sensuousness. He was an early admirer of the poetry of Leigh Hunt, whose manner was derived from Italian models, and his influence appears strongly in the productions of Shelley, often most ethereal in imagery and language. Though the conceptions of Shelley were derived from imaginative philosophy and from speculations on elemental nature, rather

than from human nature and real life, yet he was instinct with a love and intellectual sense of ideal beauty, which appear in single thoughts and images in his larger productions, and especially in some of his lesser poems, as the "Sensitive Plant," the "Skylark," and the "Cloud." Thomas Moore, a writer of surpassingly beautiful songs and of light and elegant satires, displayed his highest powers in the four oriental tales of which "Lalla Rookh" is composed, remarkable for their splendor of diction and copiousness of imagery. George Crabbe, "nature's sternest painter, yet the best," produced strong impressions by elaborately chronicling a series of minute circumstances; and in brief passages, as in "Sir Eustace Grey," rises to a fine imaginative energy. Samuel Rogers (1763-1855), the contemporary of a long series of poets, followed no one of the new tendencies, but attained high artistic excellence in the heroic couplet, with a nicety of taste and grace of sentiment worthy of Pope and Goldsmith. Campbell had a higher genius with an equal culture; amid the disasters of the time he conceived of lighting "the torch of hope at nature's funeral pile," and in his lyrical pieces he gave to romantic conceptions a classical elaboration and finish which was hardly attempted by his contemporaries. Charles Lamb, a peculiar and happily wayward genius, wrote almost nothing that is not exquisite, and his few poems, like his essays, reveal an original wit and genial character, moulded by sympathetic study of the old English writers. His reputation rests chiefly on his "Essays of Elia," than which the literature contains few things finer. The poems of Thomas Hood, whether serious or comic, are pregnant with matter for thought. Though a singularly clever rhyming punster and jester, his main strength lay in "the homely tragic," the simple pathetic, in lyrics like the "Song of the Shirt" and the "Bridge of Sighs." In his comic pieces, the "Last Man," "Miss Kilmansegg with her Golden Leg," and others, as perhaps in those of every truly humorous writer, may be detected a deep vein of earnest pathos and tragic power. The Scotch poet James Hogg (the Ettrick Shepherd), with a rare imagination, sometimes excelled marvellously in describing things that transcend nature's laws; and his story of "Kilmeny," a child stolen by the fairies and conveyed to fairy land, is a most charming example of pure poetry. The best compositions of Allan Cunningham are ballads and songs of an intensely national character, as the "Mermaid of Galloway," "She's Gane to Dwall in Heaven," and "My Nannie, O;" and William Motherwell was successful both in martial pieces, as the "Sword Chant of Thorstein Raudi" and the "Battle-flag of Sigurd," and in plaintive strains, as the ballad of "Jeanie Morrison." Many of the poems of Walter Savage Landor are attempts to reproduce the genius of ancient Greek poetry, and, though they have fine and highly intellectual passages, they seem foreign to England and not akin to modern times. He has a surer rep-

utation for his remarkable prose works, the chief of which is a series of "Imaginary Conversations." Among the minor poets of this period are Henry Kirke White, Grahame, Bowles, Hamilton, Lloyd, Lovell, Dyer, Cary, Wolfe, who deserves special mention for his short poem on the "Burial of Sir John Moore," Montgomery, Hartley Coleridge, Heber, Keble, Milman, Croly, James and Horace Smith, Pollok, Procter, Elliott, Clare, Barton, Sterling, Bailey, Bayley, Milnes, Swain, Mackay, Aird, Bowring, Praed, Tennant, Herbert, Moultrie, Maginn, Anster, Barham, the author of the "Ingoldsby Legends," Trench, A. A. Watts, Tupper, Thomas Davis, Mangan, Mahoney, Allingham, Barnes, Edward Robert Bulwer (Owen Meredith), Heraud, Matthew and Edwin Arnold, W. O. Bennett, Alexander Smith, and Gerald Massey. The most popular English poetess in the first quarter of this century was Mrs. Hemans, among whose numerous productions are some that are melodious in expression and touching in sentiment, tending especially to purify the passions and sanctify the affections. The dramatist Joanna Baillie wrote also ballads and metrical legends. Caroline Bowles (Mrs. Southey) displays in many of her slight pieces remarkable elevation and simplicity of feeling. Mary Howitt excels in ballad poetry, and in writings marked by innocent mirth and playful fancy, designed for the young. In contrast with her easy simplicity are the elaborate and impassioned poems of Mrs. Norton, who has been called the Byron of modern poetesses. L. E. Landon checked the diffuseness and efflorescent excess of her early productions, which are distinguished at once for vivacity and melancholy, and gave concentration of thought and style to the verses written not long before her mysterious death. Her "Ethel Churchill" gives her a place also among novelists. Other poetesses of the time are Mrs. Blackwood, Lady Flora Hastings, Harriet Drury, Camilla Toulmin (Mrs. Crosland), Mrs. Ogilvy, Adelaide Procter, and Eliza Cook. The greatest living English poets are the laureate Tennyson and Mr. and Mrs. Browning, who represent what may perhaps be termed a metaphysicoromantic tendency.—The most successful dramatic pieces of this epoch have been those of Joanna Baillie, remarkable for their unity of idea and intellectual completeness, the "Bertram" of Maturin, the happily constructed tragedies of Knowles, the "Lady of Lyons" and "Richelieu" of Sir Edward Bulwer Lytton, the "Julian" and "Rienzi" of Miss Mitford, the "Ion" of Talfourd, the "Fazio" of Milman, the comedies of the younger Colman, the plays of Mrs. Inchbald, the "Road to Ruin" of Thomas Holcroft, the "Honeymoon" of John Tobin, and various plays of O'Keefe, Reynolds, Morton, Poole, Planché, Marston, Jerrold, Buckstone, Taylor, and Bourcicault. The "Remorse" of Coleridge, the "Bride's Tragedy" of Beddoes, the "Tragedy of Galileo" of Samuel Brown, the "Athelwold" of William Smith, the "Philip van Artevelde" of Henry Taylor, the "Legend

yard, Fellows, St. John, Fraser, Burnes, Barrow, Harris, Burton, Kinglake, Warburton, Stanley, Atkinson, and Livingstone; of the latter, the principal are the works of Herschel, Brewster, Buckland, Davy, Lyell, Whewell, Nichol, Prichard, Pye Smith, Hugh Miller, Wilkinson, and Owen. In archæology, the names of Young and Wilkinson on Egyptian subjects, of Rich and Layard on Babylonian and Assyrian, and of Rawlinson on Persian, have attained high distinction. The work of Edward W. Lane on the "Manners and Customs of the Modern Egyptians" is unequalled as a minute and faithful delineation of an oriental people. In biographical works, this period is peculiarly rich. The most popular and important of these are the lives of Nelson and Wesley by Southey, of Sheridan and Byron by Moore, of Petrarch and Mrs. Siddons by Campbell, of Burke and Goldsmith by Prior, of Goldsmith and the statesmen of the commonwealth by Forster, of Napoleon and the English novelists by Scott, of British painters, sculptors, and architects by Allan Cunningham, of the statesmen and men of letters and science of the reign of George III. by Brougham, of the chancellors and chief justices of England by Lord Campbell, of British military commanders by Gleig, of eminent statesmen and great commanders by James, of Howard, Blake, and Penn by Hepworth Dixon, of Napoleon by Hazlitt, of Sir Walter Scott by Lockhart, of Charles Lamb by Talfourd, of Campbell by Beattie, of Mackintosh by his son, of Horner by his brother, of Sydney Smith by his daughter, of Charlotte Brontë by Mrs. Gaskell, of Dr. Arnold by Stanley, of Goethe by Lewes, and of Moore by Lord John Russell. Among miscellaneous writers on literature, Isaac Disraeli, Sir Egerton Brydges, and John Foster became prominent near the beginning of the century. The number of books has often been increased by miscellaneous collections from the reviews, journals, and magazines, as the "Noctes Ambrosianæ," from "Blackwood's Magazine," chiefly by Prof. Wilson, the "Essays" of Jeffrey and Sydney Smith, Macaulay and Carlyle, from the "Edinburgh Review," the witty productions of Douglas Jerrold, collected from "Punch," and many of the writings of Hazlitt and De Quincey. Cobbett and J. Wilson Croker achieved distinction as political pamphleteers, and the latter also by his vigorous and pungent articles in the "Quarterly Review." Important contributions have been made to English art literature by Lindsay, Eastlake, Leslie, and especially by Mrs. Jameson and John Ruskin. The principal metaphysical writers of the Scottish school were Dugald Stewart, Dr. Thomas Brown, and Sir William Hamilton; the more peculiar tendencies of the English mind appeared in Paley; Bentham is the author of important works on jurisprudence, J. Stuart Mill on logic and political economy, and Archbishop Whately on logic, political economy, and theology. The most remarkable sermons have been those of Alison, Robert Hall, Chalmers, and Robertson; and

the "Tracts for the Times," and the writings in support of them or antagonistic to them, constitute an interesting department of theological literature. The names of Cardinal Wiseman, J. H. Newman, and Faber are particularly distinguished in Catholic theology; of Pusey and Froude in the Anglo-Catholic movement; and of Dr. Arnold, the brothers Hare, Conybeare, Maurice, and Jowitt in the broad church party of the Anglican church. F. W. Newman and James Martineau are exponents of less ecclesiastical tendencies.—The best historical and critical works on the literature of England are: Wright's "Biographia Britannica Literaria" (vol. i., the Anglo-Saxon period, 1842; vol. ii., the Anglo-Norman period, 1846); Warton's "History of English Poetry," extending to near the end of Queen Elizabeth's reign (3 vols., 1774-'81); Hallam's "Introduction to the Literature of Europe in the 15th, 16th, and 17th Centuries" (1837-'39, with additional notes in later editions); Collier's "History of English Dramatic Poetry" (1831); Chambers's "Cyclopædia of English Literature" (2 vols., 1843-'44); Lowndes's "Bibliographer's Manual" (4 vols., London, 1857 *et seq.*); and Allibone's "Critical Dictionary of English Literature" (2 vols., Philadelphia, 1858 *et seq.*). Among brief manuals are Shaw's "Outlines of English Literature" (1849), and Spalding's "History of English Literature" (1853).—For an account of the origin and growth of English magazines, reviews, and journals, see NEWSPAPERS, and PERIODICAL LITERATURE. For English art, see MUSIC, PAINTING, and SCULPTURE.

ENGLAND, JOHN, D.D., first Roman Catholic bishop of Charleston, S. C., born in Cork, Ireland, Sept. 23, 1786, died in Charleston, April 11, 1842. He studied in the schools of his native city, and at the age of 15, having resolved to enter the priesthood, was placed by his bishop under the care of the Very Rev. Dean McCarthy, who fitted him to enter the college of Carlow in 1803. During his stay at this institution he founded a female penitentiary and poor-schools for both sexes, gave a course of lectures in the parish chapel, and preached to the soldiers then stationed in the town. He was recalled to Cork in 1808, ordained priest Oct. 9, and soon after appointed lecturer at the North chapel and chaplain of the prisons. In the following May he commenced the publication of a monthly magazine called the "Religious Repertory;" in 1812 he was appointed president of the theological college of St. Mary, in which he also lectured on divinity, and about the same time he entered into politics with all his characteristic warmth. He exerted himself with some success to put down bribery at elections, and in the "Repertory" attacked the existing system of criminal jurisprudence, and opposed the project, which then found considerable favor in Ireland, of purchasing Catholic emancipation by certain concessions to the English government. The freedom of his language more than once brought him before the courts,

and on one occasion he was fined £500. Meanwhile he filled the office of bishop's secretary, performed the ordinary duties of the ministry, and founded several religious and charitable institutions in Cork. In 1817 he was made parish priest of Brandon. In 1820 he received a papal bull appointing him bishop of the new diocese of Charleston, S. C., comprising the states of North and South Carolina and Georgia, with a scattered Catholic population of about 8,000, and only 4 priests. He was consecrated in Cork, Sept. 21, and arrived at Charleston about the end of the next December. One of his first cares was the establishment of an academy and a theological seminary, in both of which he taught the principal branches, supporting the latter institution by the revenue from the former. He founded an anti-duelling association, corrected many evils which had crept into the church, visited every part of his vast, half-settled diocese, and gave special care to the negroes, for whom he always had regular services in his cathedral. With the view of defending his creed he established the "Charleston Catholic Miscellany," the first Catholic paper published in America. In 1826, at the request of congress, he preached before the senate at Washington. In 1832 he travelled in Europe and spent some time in Rome, when the pope appointed him apostolic legate to Hayti. He visited that island twice in discharge of his functions, returned to Rome in 1833, and made two more voyages to Europe in 1836 and 1841. His death was brought on by sickness contracted on a stormy passage home, hastened by unusual exertion in preaching immediately after his arrival. His learning and controversial powers, his high moral character, and above all the heroism which he displayed during a season of yellow fever, gave him a standing among persons of other denominations in Charleston which no member of his faith had held there before; and the strange spectacle was sometimes witnessed of the Catholic bishop in his robes preaching on Sunday in a Protestant church to a Protestant congregation at the request of the latter's pastor. His incessant activity won for him at Rome the sobriquet of *il vescovo a vapore*, "the steam bishop." Bishop England left a great number of theological, controversial, historical, and miscellaneous writings, most of which originally appeared in the periodical press. A complete edition of his works, edited under the direction of his successor, the Rt. Rev. I. A. Reynolds, D.D., in 5 vols. 8vo., appeared in Baltimore in 1849.

ENGLISH, GEORGE BETHUNE, an American literary, military, and political adventurer, born in Boston in 1789, died in Washington in Aug. 1828. He was graduated at Harvard college in 1807, studied law in Boston, and was admitted to the Suffolk bar, but never engaged in practice, becoming first a theoretical reformer and disputant, and then a student of divinity at Cambridge. During his theological course he began to doubt the truth of Christianity, and published a work in favor of Judaism, entitled the "Grounds of

Christianity Examined, by Comparing the New Testament with the Old" (Boston, 1813), which was answered in the following year by Edward Everett, at that time pastor of the Brattle street church in Boston. English then vainly sought to obtain a commission in the U. S. army, was for some time engaged in editing a newspaper in the West, and finally sailed to the Mediterranean as a lieutenant of marines in a U. S. ship of war. Arriving in Egypt, he professed Mohammedanism, and having liberal offers made to him, accepted a commission in the army of Ismael Pasha, who was sent by Mohammed Ali in 1820 in command of an expedition against the tribes of Sennaar upon the upper Nile. As an officer of artillery, English performed important services. He employed camels to drag cannon, and attempted to revive the ancient scythe war chariot, so modified as to be propelled by horses under cover in the rear; but the model which he constructed was destroyed through jealousy. Though defrauded of his promised reward, he obtained a practical knowledge of the country and people, and became an agent of the American government in the Levant. He returned to America in 1827, and took up his residence in Washington. He had a very versatile genius, and especially excelled in acquiring languages. At Marseilles he passed for a Turk with a Turkish ambassador, who believed no foreigner could so perfectly speak his language; and at Washington he surprised a delegation of Cherokees by disputing with them in their own tongue. He wrote an answer to S. Cary's review of his first book; a letter to W. E. Channing regarding his two sermons on infidelity (1813); and a "Narrative of the Expedition to Dongola and Sennaar" (London, 1822), which was republished in the United States in 1823.

ENGLISH, THOMAS DUNN, an American author, born in Philadelphia, Penn., June 29, 1819. He received the degree of M.D. from the university of Pennsylvania in 1839, and having subsequently studied law was admitted to the bar. He has written two novels entitled "Walter Woolfe" and "MDCCCXLII," and has edited and contributed to a variety of journals and magazines. In 1855 he published a collection of his miscellaneous poems. He now resides in the vicinity of New York, and is connected with the press of that city.

ENGLISH CHANNEL, that portion of the Atlantic which separates England from France, extending on the N. from Dover to the Land's End, and on the S. from Calais to the island of Ushant. At its W. end it is 100 m. wide; on the E., where it is united to the North sea by the strait of Dover, it is about 20 m. across, and its greatest width is about 140 m. The English coast of the channel is 390, and the French 570 m. in length. In it are the isle of Wight, Guernsey, Jersey, and other islands. A current appears to run through it from the W. On the English coast it has some excellent harbors, but those on the French side, excepting the artificial

port of Cherbourg, are too shallow for men-of-war. Important pilchard, mackerel, and oyster fisheries are prosecuted in its waters. From its peculiar shape the French call it *la Manche*, "the sleeve."

ENGRAFTING, the process in horticulture by which varieties of one kind of plant may be induced to grow artificially upon other individual varieties or species. No attempts toward engrafting plants on others which do not belong to the same natural order have been successful. Generally speaking, varieties succeed best on varieties, species on species, or species and varieties on allied genera. All our cultivated fruits, for instance, are improved varieties of some original species, now not ascertained. Out of thousands of varieties raised from the seeds of some previous excellent variety, very few have any merit, the tendency being to return to the original specific type. When a new and decidedly valuable variety occurs, it becomes a matter of importance to perpetuate it in as great a number of individual plants as possible. The trifling effect that the stock has upon the scion enables the poorer varieties to be employed in furnishing the trunk and root to the smaller and younger scion. A piece of well-ripened wood, in the form of a twig having 3 or 4 buds upon it, is thus transferred to the poorer kind, and forms a living extremity, which extends itself into branches and forms a new head or top. In this way varieties of apples and of pears may be engrafted upon the wild crab, or upon paradise stocks; but the result is to dwarf and stint the growth of the freer-growing scion. Here, varieties are assisted by species; and *vice versa*, species, or varieties of one kind of species, may be propagated on those of another. The pear, too, in its almost endless varieties, may be engrafted upon the apple, quince, hawthorn, and mountain ash, where we see species and varieties of species flourishing upon entirely distinct genera. The stone fruits engraft with more difficulty, yet the varieties of the plum can be engrafted upon plum stocks or upon the apricot, the cherry upon cherry, &c. Nut-bearing trees are often engrafted to insure a better sort of nuts, and ornamental trees and shrubs of rare and curious kinds can be increased in the same way. The evergreen pines have been thus propagated, and so too have beeches and ashes, as well as the lilac upon a distinct species of lilac, and even the common lilac upon the ash. The rose acacia thrives finely upon the common locust, and forms a highly ornamental head in 2 or 3 years. Many choicer foreign shrubs and plants cultivated in greenhouses are thus profitably increased, of which the camellia is a notable example. The daphne, with fragrant blossoms, a favorite in the parlor, unites well with the spurge laurel of England; the oleander with double flowers unites with the single kind, and the succulent-stemmed cactuses and their allies can be engrafted upon each other. Remarkable stories are in common circulation of extra-

ordinary instances of engrafting the fig tree upon the olive, the plum upon the pear, and the rose upon the black currant, and even of causing a great many kinds of flowering plants to grow upon a single and distinct stock; but all such are fallacies. In some countries plants are sold in the market places, so prepared as to deceive the unwary. A hollow-stemmed and woody kind is selected, and a variety of others are inserted; or their seeds are so sown as to enable their roots to descend into the hollow part, where they will meet with suitable soil and nourishment. In this way, the different kinds of leaves and flowers, being made to intermingle, serve to produce a strange and anomalous effect. Something of the same sort may be noticed in the chance springing up of currant bushes in the cracks and crevices of trees, and of the mountain ash in the rotten hollows of the large trees of our cities, the decaying wood and the dust swept by the winds into these cavities affording them a partial and limited support. In some other instances, the expansion of the leaves, and a feeble development of the engrafted scion upon another plant not kindred to it, seem for a while to show the possibility of such a union; but the effect is so transitory and the death of the branch is so certain, that such instances are no exception to the general rule.—A great variety of processes in engrafting are possible, but the principle of the operation is the same in all. In the vegetable kingdom, a distinct vitality, capable of development to an unlimited extent, is resident in every individual bud. In the growth of all exogenous plants there is a peculiar organization between the inner surface of the bark and the outer surface of the wood, which is called the alburnum. The vital power of the plant resides chiefly here. Thus the woody portions may be removed without affecting the life of the tree, or the bark may be stripped off without killing the tree, provided no injury is sustained by the alburnum. This vitalized organization renews the bark and the wood, so that its presence is essential. It is then equally essential that the alburnum of the scion, as it is termed, be brought into exact and close contact with the alburnum of the stock; thus the greatest amount of contact of the alburnum in both will insure the most perfect success.—In this country, the most common and likewise the most clumsy, and yet quite as often the most successful plan of engrafting, is called **CLEFT GRAFTING**, and is practised upon the heads of large or old trees by lopping the extremities of the branches. Sometimes the entire tree of 4 or 5 inches diameter is cut to a bare stock and used in the same manner. The stock, whether trunk or branch, is cut over horizontally with a sharp saw, and the surface pared smooth with a knife; a cleft about 2 inches deep is made in the stock with a splitting knife and hammer; the scion to be engrafted is prepared by sloping its lower end in the form of a wedge about an inch and a half long, leaving it a little thicker

ENGRAVING

are said by Du Halde to be 1120 years before that from them the rope. It is first mentioned by an Italian Cunio, who executed in the year 1285, and who went through Venetian opinion of Outley, "A History of Venice of 1441," in which it is stated of making cards and to decay, owing to iron, and the introduction of work printed and, as altarpieces or images, was in consequence of the existence of the art in other places also unknown period previous is known, were in use for multiplying pictures that impressions carved blocks of wood. In the 15th century this was common, the artists being, and also as *Ferrara*. They applied their art also, and engraved, impressed some rude subjects, the printed side of a large page, pasted together. One of these wooden cuts, of folio size, and precious, near Memmingen, Christopher carrying "Sea," and its illustration those on the playing card possession of Earl of Devon, of these illustrations vary from 40 to 100 on one side only of the card. In the beginning it was of movable types art of printing. Copied as well as wood, about the same time. A German copper-plate of the date 1461, and is the oldest specimen. It is of the earliest use, a native of Florence, as a goldsmith, for churches, &c., by the metal a black-col-

made the tallo plate extensive as Botticelli rapidly printed in Germany of whom Albrecht Dürer also executed etching services in Germany, who signs. The first English work called engraving appeared in 1564, in a volume of "The Art and Mystery of the Copperplate Press," which, however, when the first English engraving, "The Strange Case of the Dog in the Street," brought to light. At present extensive to the design of books no longer has how engravers will come to the fore.

Morghen, "Transi-

giola after Raphael, are among the most costly productions of the art. Schiavoni, the Amsterdamer, Bettelini, Longhi, Porporati, Favon, the latter a scholar of Raphael Morghen, and others, have engraved with success many of the works of the old masters. Toeschi, who died in 1854, took high rank among line engravers by his print of the "Entry of Henry IV. into Paris," after the picture by Gérard, as well as by his "Descent from the Cross," after Volterra, *Spasimo di Sicilia*, after Raphael, and other works from the old masters. Rosaspina, Bisi, Mercuri, and others, have produced meritorious prints from masters both old and modern. In Germany the art has witnessed a steady improvement since the commencement of the century, particularly within the last quarter of it, although engraving on wood or stone is probably more extensively practised than line engraving or the other methods of working on metal. Rahl, Henz, Reindel, Umer, Laybold, Kemler, Kobell, Barth, Klein, J. H. and J. J. Lips, Steinla, and others, have gained high rank as line engravers; and Christian Friedländer, who died in 1816, aged 33, executed a print from Raphael's *Madonna di Brera*, which is regarded as one of the noblest works of the graver. His father, J. G. von Friedländer, also a good engraver, and among others executed the well known print of "Bunker Hill" from Trumbull's picture.

on the outer edge. The cleft being kept open with a wedge, the scion is carefully pushed down to the place fitting its inner bark on one side, so that the inner edges of stock and scion may coincide. The wedge is then withdrawn, and the scions are retained in place by the springing together of the cleft, when the graft is covered with some kind of composition, either of clay or of wax, in order to exclude the air and to facilitate the union.—In England and on the continent, another process, called WHIP or TONGUE GRAFTING, is mostly employed. This is considered the most expeditious. The stock upon which it is performed must be slender, from the size of a goose quill to any diameter which coincides with the thickness of the graft. Some smooth, clear part of the stock being selected, it is in heading it off sloped on one side with a knife to a very acute angle, and a slit made on the lower side of the slope to receive the wedge or tongue of the graft. A scion having 4 or 5 buds, and of the size to match the stock, should be sloped at the bottom so as to accurately fit it. The rinds of both should be made to correspond; a string of soft bast should be wound round them to hold them in place, both covered with the grafting composition. After the graft pushes its buds, the binding should be loosened and finally removed, when the adhesion is completed. Pieces of the roots of apple, quince, or pear are also whip-grafted and planted out, just exposing the top of the scion to the air; these unite firmly and make vigorous plants. This may be practised also on flowering shrubs.—In SADDLE GRAFTING, the scion is cleft instead of the stock; the stock is pared away on each side to an acute angle, so as to allow the scion to sit or ride upon it, and the union of the edges of the barks made as complete as possible on each side.—CROWN GRAFTING is practised upon large trees of which the wood is too hard and stubborn to be cleft. Several scions are pared away on one side of the lower end for about 2 inches, so as to make that side flat and leave a shoulder forming a right angle with it. The head of the stock being sawn off horizontally, the bark is gently raised from the wood and thin wedges inserted. The scions are now pushed under the bark, their shoulders resting on the crown of the stock; the wedges being withdrawn, the whole are tied in by soft bast or other string, and composition of wax or clay laid over, to prevent any wet penetrating the wounds. After the grafts have grown, and made long, tender shoots, which they will be apt to do with much rapidity and vigor, they should be secured to long stakes planted near the stock and rising above it, so as to save the newly formed top from breaking off at the junction with the stock, by the force of winds acting upon the luxuriant foliage.—Sometimes it is essential to replace limbs that have been broken from young trees, or from branches of older ones, and to restore the symmetry of form; and this is done by SIDE GRAFTING. Here the bark and a little of the wood is sloped off from the side of the trunk

or of the branch, and the lower end of the scion is cut so as to fit the part as near as possible; it is then fixed in the branch or trunk, first tonguing both as in whip-grafting, tying them with bast, and claying over.—INARCHING is only a kind of engrafting, and is employed where the cut scion is not to be easily united to the desired stock. Two branches, or two stocks of the two distinct plants, are brought close together, and, the prepared surfaces being matched and tongued, the whip-grafting is employed; after a while a perfect union will have taken place, when the engrafted portion is to be separated from its parent root, and it henceforth becomes the branch or top of its new foster mother.—BUDGING (which see) is only a variety of this art.—The practice of engrafting seems to have been long known; but the processes have multiplied with the discoveries and improvements in horticulture.

ENGRAVING, properly the art of cutting designs upon hard surfaces, as of wood, stone, or metal—a species of sculpture upon plane surfaces. In this sense the art was practised at very remote periods, mention being made of the work of the engraver in Exodus xxxv. 35. In its modern use the term more commonly designates the production of designs by cutting or by corrosion upon the face of blocks or metallic sheets, which are to be used for transferring the figures by pressure to paper or other soft substances, in order to multiply copies. Engraved plates serve therefore a similar purpose to moulded types used for printing; but the art of preparing the plates is of much higher order than the manufacture of types or the setting of them to form a page. For types are only fixed, arbitrary symbols, which have no expression of their own; while engravings are pictures, from originals drawn it may be by masters in painting or design, which cannot be transferred line by line to a new surface, even with the aid of ingenious mechanical devices, unless the copier can enter somewhat into the spirit of the artist, and thus catch the expression of the work. The relation of the engraver to the painter, as remarked by Allan Cunningham, is that of the translator to the author. By means of the art the masterpieces of sculpture and painting are placed, in faithful copies, within the reach of all; science is made familiar by cheap illustrations, that reach the understanding where words fail; instruction and amusement are presented by it in wonderful variety in the constant succession of cheap ephemeral productions which are a peculiarity of this age; and monetary transactions are facilitated by the unlimited number of facsimiles of intricate designs, furnished at trifling cost for a single copy, but difficult and expensive to counterfeit. The period when engraved plates or blocks were first printed from is involved in much obscurity. The Greeks are said by Herodotus to have prepared maps upon metallic plates (500 B. C.), which might very well have served for furnishing copies by impression, but were probably never applied

to this use. The Chinese are said by Du Halde to have practised the art 1120 years before Christ, and some suppose that from them the art was transferred to Europe. It is first mentioned as having been practised by an Italian family of the name of Cunio, who executed wood engravings in the year 1285, and who may have received the art through Venetian merchants. Such is the opinion of Ottley, the author of the "History of Engraving." A decree of the magistracy of Venice of 1441 has been brought to light, in which it is stated that the art and mystery of making cards and painted figures had fallen to decay, owing to their extensive importation, and the introduction into the city of such work printed and painted on cloth or paper, as altarpieces or images and playing cards, was in consequence prohibited. This indicates the existence of the art not only in Venice but in other places also at that time, and for an unknown period previously. Playing cards, it is known, were in use in 1275, and it was probably for multiplying copies of their simple devices that impressions were first taken from engraved blocks of wood. In the beginning of the 15th century this was an established trade in Germany, the artists being known as *Briefmaler*, and also as *Formschneider*, or figure cutters. They applied their pursuit to higher objects also, and engraved prints of saints, and even impressed some rude forms of books upon sacred subjects, the printed matter occupying only one side of a large page, and two of these being pasted together. One of the earliest remaining of these wooden cuts, bearing the date of 1423, is of folio size, and preserved in a convent at Buxheim, near Memmingen. Its subject is "St. Christopher carrying the Infant Jesus over the Sea;" and its illuminations are of the style of those on the playing cards. It is now in the possession of Earl Spencer, in England. A specimen of these illustrated books was called *Biblia Pauperum*, "Bible of the Poor." The editions vary from 40 to 50 leaves, small folio, printed on one side only of the paper. From these rude beginnings it was a short step to the invention of movable types and the discovery of the art of printing. Copper was very soon employed as well as wood for engraving upon, and at about the same time in Germany and in Italy. A German copperplate print is in existence of the date 1461, and it is unlikely that this was the oldest specimen. But Vasari gives the credit of the earliest use of this metal to Finiguerra, a native of Florence, who practised, in his occupation as a goldsmith, the engraving of plate for churches, &c., by running into lines cut in the metal a black-colored alloy of silver, lead, copper, sulphur, and borax, called *niello*. The surface being polished, it was thus beautifully ornamented according to the skill and taste exhibited in the pattern. It was for the purpose of obtaining a copy of the engraved figure that Finiguerra is said to have made an application of soot and oil, and taken an impression on damp paper; and thus was

made the first representation on paper from a metallic plate. The art was at once taken up and extensively practised. Painters of distinction, as Botticelli, gave their attention to it, and it was rapidly perfected. This was especially the case in Germany and the Netherlands, great numbers of eminent men adopting the art, among whom Albert Dürer is particularly distinguished. Rembrandt, Vandyke, and other great painters, also executed valuable works of art with the etching needle, and Raphael highly prized the services of the great Italian engraver Marc Antonio, who transferred to copper many of his designs. The art appears to have been introduced into England at an early period, an illustrated work called the "Golden Legend" having appeared in 1483, and in 1545 was published Vesalius's "Anatomy," in Latin, illustrated with copperplate engravings. Maps of English counties were engraved in 1579. Little progress, however, was made previous to the 18th century, when Vertue and Hogarth, and subsequently Strange, Woollett, Bartolozzi, Sharp, and others, brought the art to a high degree of excellence. At present engraving on wood or metal is more extensively practised than ever, owing chiefly to the demand for prints for the embellishment of books or illustrated periodicals. Italy is no longer preëminent for her engravers; she has however within the century furnished some engravers of transcendent merit, whose works will compare with the best of their predecessors. At the head of these stands Raphael Morghen, whose "Last Supper" after Da Vinci, "Transfiguration" and *Madonna della Seggiola* after Raphael, are among the most costly productions of the art. Schiavoni, the Anderloni, Bettelini, Longhi, Porporati, Pavon, the latter a scholar of Raphael Morghen, and others, have engraved with success many of the works of the old masters. Toschi, who died in 1854, took high rank among line engravers by his print of the "Entry of Henry IV. into Paris," after the picture by Gérard, as well as by his "Descent from the Cross," after Volterra, *Spasimo di Sicilia*, after Raphael, and other works from the old masters. Rosaspina, Bisi, Mercuri, and others, have produced meritorious prints from masters both old and modern. In Germany the art has witnessed a steady improvement since the commencement of the century, particularly within the last quarter of it, although engraving on wood or stone is probably more extensively practised than line engraving or the other methods of working on metal. Rahl, Hess, Reindel, Umer, Leybold, Kessler, Kobell, Barth, Klein, J. H. and J. J. Lips, Steinla, and others, have gained eminence as line engravers; and Christian Friedrich von Müller, who died in 1816, aged 33, produced a print from Raphael's *Madonna di San Sisto*, which is regarded as one of the noblest achievements of the graver. His father, J. G. von Müller, was also a good engraver, and among other works executed the well known print of the battle of Bunker hill from Trumbull's picture.

called the outline tool, the boundary lines of the portions to be removed are slightly cut in the wood, which are to form the light parts of the engraving. The lines marked in the drawing are the prominent parts, which are to receive and transfer to the paper the ink or other coloring matter; in copperplate engraving the lines are sunk into the metal. There is a method of wood engraving in which the ground is inked, and the lines sunk in the block appear white upon the paper, thus producing a good effect for outline sketches at little cost. This, however, differs from copperplate engraving in the ground instead of the lines receiving the ink. The outlines being cut into the wood, the portions to be removed are next cut out by means of gravers and gouges of different sizes. The blocks of small woodcuts are so shaped as to be inserted in the page with the types, their surface being brought to the same level, and the printing is then effected precisely as if the whole were types. In the same manner they are blocked in stereotype plates. The thickness of the blocks of wood is the height of common types. An application of flake white or bath brick and gum water is made upon the surface of the wood in order to receive the lines of the drawing. *Chiaroscuro*, or *claro obscuro*, is a method of wood engraving in which a series of blocks are used, the first having merely the outlines of the print, the second only the less dark shadows, and the third those more dark, and so on if more are used. An impression is taken from each in succession. In some instances a copper plate is used to give the outlines in a heavy, dark style. It is on this principle the printing of colored engravings is effected, a series of blocks being employed, each one having its own color and being used in turn, as practised in **CALICO PRINTING**, which see in this work, vol. iv. p. 224.—**COPPERPLATE ENGRAVING** is practised by various methods, the most simple of which is to cut in the lines of the drawing with sharply-pointed gravers, after the sketch has been transferred to a thin covering of white wax melted uniformly over the face of the hammered and polished metal. The transfer is effected by laying a tracing of the design in black lead pencil face down upon the wax and subjecting it to a heavy pressure. The lines are then distinctly seen upon the wax when the tracing paper is removed. By the use of very delicate gravers the lines are slightly marked through upon the copper, and when the wax has been melted off the engraving is completed by cutting the lines to the proper depths with suitable gravers, removing the burr which is pushed up by the graver with another instrument called a scraper, and softening the effect produced by scratches and lines cut too deeply into the metal by rubbing the surface over with the smoothly-pointed steel instrument called the burnisher. The graver or burin is similar to those used in wood engraving. The point is of pyramidal form, with unequal sides, and is kept sharp by frequent application upon an oil stone.

The handle is short, and the side on the line with the point is made flat, both for the purpose of applying the instrument at the smallest angle with the flat surface, and to cause it to remain without rolling wherever it is laid down. In use, the point is thrust forward, cutting a furrow in the metal and raising burrs by the sides of the lines. These are commonly taken off with the scraper, but in some instances those made with the finest etching needle, called the dry point, have been allowed to remain, and a pleasing effect is said to have been produced in many of Rembrandt's engravings thus treated. The polish and cleanliness of the plate are preserved by frequent rubbing with a woollen rubber wetted with olive oil. Parallel lines required in series are cut by a ruling machine. The fainter shades too delicate for the gravers are scratched in with the needle or dry point, which is held in the same way as a pencil in drawing. Such is the simplest method of line engraving on metallic plates.—Engraving by dots or punctures made in the metal to produce shades is often practised, but commonly in the etching process. The dotted style is called stippling. The effect is produced by dots made usually in curved lines with the graver, the point, or by etching; the more closely the dots are grouped together, the darker the shade. The style was much practised by the English in the latter part of the last century, and is particularly adapted for giving a soft pleasing effect in shading the limbs of the human figure, in representing flowers, &c. The work resembles painting more than line engraving. For producing the greatest delicacy in shading, the fine dry point is used. When the dots are struck in with a little hammer, the work is called *opus mallei*.—The most common method of engraving upon copper, practised also upon other metals and upon glass, is that called etching. It consists in causing an acid to bite in the lines, which have been drawn through the coating of wax, called the etching ground, upon which the acid has no effect. Albert Dürer is supposed to have invented the method, the earliest known specimens of it being among his works. The etching ground is prepared by melting in a crucible at a moderate heat 2 ounces of white wax, with half an ounce of black pitch and the same of Burgundy pitch, and stirring in 2 ounces of asphaltum in powder. When thoroughly incorporated by boiling, the mixture is poured into water. It is then separated and worked by hand into balls, which are tied up in pieces of smooth-worn silk. The application upon the plate, uniformly heated, is made by rubbing one of these balls over its surface, so that the composition melts through the silk. It is then spread evenly over the copper by a dauber, which is a bag tightly filled with soft wool and covered with smooth silk. The ground being thus evenly spread, the plate is next held over several smoking candles, till a coating of lamp-black covers the wax. The outline of the design, made with black lead pencil upon paper,

is then laid face down upon the lampblack, and by pressure between the rollers used for this purpose it is transferred to the etching ground. Sometimes the back of the sketch, which in this case is drawn reversed, is covered with whiting, and laid upon the blackened surface, and the lines then being gone over with a blunt point, they are transferred by the chalk adhering to the lampblack and wax. The lines are then drawn with etching needles through the ground to the copper, the same care being taken to preserve the proper effect of distance, by appropriate fineness or coarseness of the lines, as in a finished drawing. In order to retain the acid upon the plate, a ridge of what is called banking wax is laid around its edge about half an inch high. This is prepared by melting together two parts of pitch and one of beeswax, and adding some sweet oil. Nitric acid diluted with about 4 parts of water is then poured over the plate, and allowed to remain long enough to corrode the fainter portions of the sketch. It is then poured off, and the plate is washed with water. When dry, an application of a mixture of lampblack and Venice turpentine, called stopping ground, is made with a camel's hair brush to these portions, by which further action of the acid is prevented. By a renewed exposure to the acid the parts not protected are more deeply corroded, and a correspondingly bolder shade will be imparted to these lines. Another application of the stopping ground gives another gradation of tint, and as many of these may be obtained as the times of repeating the process. The border of wax is then melted off, and afterward the etching ground is so softened by heat that it is wiped off with a rag moistened with olive oil. Portions of the plate that require it are then gone over with gravers, and the finishing touches are thus put on. It is often the case that a part of the work is done wholly by the graver after the other portions have been etched. The shades are frequently produced in the stippling style both by etching and afterward in finishing by striking in the dots. It is apparent from this description that the art of engraving can be practised only by good draughtsmen; and that as clear ideas are requisite of the different grades of the shading and of the methods of producing these effects, as if the sketches were to be produced for the first time upon paper.—The styles of engraving known as *aquatinta* and *mezzotinto* require notice. The former is so named from the similarity of the effect to water-color or Indian ink drawings. After the design is etched in outline, and the etching ground removed, a solution of resin or of Burgundy pitch in alcohol is poured over the plate as it lies in an inclined position. As the alcohol evaporates, the resinous matter is left in the form of granulations over the surface of the plate. The design is then drawn with a gummy sirup called the bursting ground, which is applied wherever a shade is to be produced. The lights are left untouched. The whole is next covered with a coating of turpentine varnish, and a

border of wax is raised around the plate. Water is poured upon it and left for 15 minutes, when the bursting ground cracks open, exposing the copper. It is then ready for the nitric acid, which is used as in etching, and may be several times applied after each stopping out of the portions sufficiently corroded to produce the desired shades. The bursting ground is not always required, the acid being applied directly upon the granulations, which protect the parts they cover, and the varying shades are produced by repeated corrosions and as many stoppings out. By some artists certain resinous powders are dusted upon the plate instead of obtaining the granulations by the alcoholic solution. Gum sandrac is used for this purpose, or the purest resin more or less finely pulverized, and sifted through muslin upon the plate, to which the particles attach themselves on its being heated. Colors are sometimes applied to the plates, and the design is at once printed in its intended colors; but where several colors are employed in contact with each other, it has been customary to use as many different plates, one for each color, and print in succession, the plates being kept in their exact places by fitting upon 4 fixed pins that pass through holes in their corners. This method is practised in engraving upon cotton cloth. (See CALICO PRINTING.) The *aquatinta* process is a French invention, dating from 1662. It has been a favorite style of engraving with English artists, whose works by this method are of the highest merit. The same remark may also be made of the *mezzotinto* or half-painted style, which was introduced into England by Prince Rupert, who may have invented the process, or possibly learned it, as some say, from an officer named Ludwig von Siegan, who was in the service of the landgrave of Hesse. The invention has also been credited to Sir Christopher Wren. The method is particularly appropriate to portrait and historical engravings and night scenes requiring a very dark ground. The preparation of the plates is a mechanical work, performed by running little toothed wheels set in handles over their whole surface, and by a rocking motion causing them to make indentations and raise corresponding burrs or barbs in lines variously directed. These instruments are called cradles. They are made of various degrees of fineness, and the difficulty of the process is in the skilful adaptation of the proper shades in the ground produced by these tools. After the whole plate has been thus covered, the burrs are rubbed off with scrapers and burnishers wherever lights are desired, and deeper shades are made, if necessary, by increasing some of the indentations. The lights and shades are thus brought out, and an agreeable softness is produced by the harmonious gradations of the tints more easily than by the other methods of engraving. The plates do not wear very well in printing unless steel is substituted for copper. By combining etching of the outlines with the *mezzotinto* the process is much improved, and a more decided character is given to the prints. *Mezzotint* plates are now sold

for the trade supply, which are prepared by a machine invented by Saulnier for ruling lines. The cross ruling is sometimes so fine that the ground appears black.—**ENGRAVING ON STEEL** may be regarded as an American process, invented by Mr. Jacob Perkins, of Newburyport, Mass., though the metal had once been used in England in 1805 in the print of the ceiling of the star chamber in Smith's "Topographical Illustrations of Westminster." Its great advantage consists in this—that the plates, after having been engraved by the methods used for engraving copper, can be hardened, so that they are capable of transferring the design by pressure upon other softened plates of steel; and these, being hardened, may perform the same office upon others, and so an indefinite number of plates may be obtained from one engraved. This is peculiarly the invention of Mr. Perkins, and its most important application is for engraving bank notes, for which the most expensive designs are desirable in order to prevent counterfeiting. This branch of the art is especially treated below. The design being once engraved upon a steel plate, any number of copies may be produced from it. Perkins prepared his plates by first transferring the impression from the original plate to the surface of a soft steel cylinder by repeatedly rolling this under heavy pressure over the hardened plate. The cylinder receives the impression in relief, but being hardened, it transfers it to successive soft plates like the original. Unless an immense number of impressions is required, a soft steel plate is sufficiently hard without subjecting it to any further process, and for the most delicate works of art in this metal this is preferable, as in the transfer there is always some risk of injury. A soft plate has furnished as many as 95,000 impressions without deterioration. The hardening is effectually accomplished by dipping the plate, in order to heat it, in a bath of melted fusible alloy, and then cooling in water, which it is perhaps better to heat to the boiling point. In preparing the soft plate for etching, the lines should be cut into the steel, as the acid would be likely to corrode a broad instead of a deep line. In the ruling machine of Mr. William Lowry a diamond point is sometimes employed for cutting the lines.—**Stones** are often engraved, a dry point being used as in engraving metals. The work does not produce so fine effect as engraving upon metal, but it is well adapted for mechanical drawings, maps, and similar styles. Glass may be engraved by sketching the design upon it with a solution of beeswax and turpentine, and then causing the surface to be corroded by the fumes of hydrofluoric acid generated by the action of sulphuric acid upon pounded fluor spar, which is placed in a shallow basin of lead and gently heated. Or the glass may be covered with a thin layer of beeswax, through which the design is etched, and this is then subjected to the action of the vapor, as the plate is laid face down upon the basin. The

corrosion is completed in 4 or 5 hours, when the applications should be removed, and the glass cleaned with oil of turpentine. The process is conveniently applied to the marking of bottles for the chemist or apothecary. The deep transparent etching is produced by the direct application of the liquid acid to the glass; the more delicate opaque lines by the vapor. (See **FLUORINE**.)—In order to lessen the tedious mechanical operations connected with engraving, attempts have been made to obtain directly by chemical means from the drawings engraved daguerreotypes for printing. The investigations of Mr. George Mathiot of the U. S. coast survey in this direction particularly demand notice. They were prosecuted with the object of applying the process to the printing of the maps of the survey; and though the method is not claimed to be altogether original with him, it has been by no one else so perfected and practically applied. The subject is treated in detail in the "Report of the U. S. Coast Survey for 1854." In a daguerreotype the light and dark shades are chemically different, and hence are differently susceptible to the same chemical reagent. M. Donné proposed to etch the plate with nitric acid, which he inferred would act upon the dark shades, supposed to be silver, and leave the lights, which are mercury. This has not been found successful. Prof. Grove proposed etching the daguerreotype plate by the voltaic current, making it the positive electrode in a bath of strong hydrochloric acid. Mr. Mathiot succeeded in obtaining engravings of great beauty and delicacy by this method, but in only two instances in more than 100 trials were the lines deep enough to print from. The most satisfactory results were obtained by the use of a carefully prepared copper plate, upon which was deposited a film of silver of about $\frac{1}{4}$ of a grain to the square inch. On this, after being washed in distilled water, dried and slightly buffed, the daguerreotype is taken. It is then submitted to the action of the voltaic current in a bath of chloride of sodium, until the silver is etched through to the copper, at which the action stops; but unless the plate be immediately removed from the bath, the lines will spread in the silver film and blur the effect. The time to remove the plate is determined only by practice and dexterity. After removal the plate is washed by immersing it in water; and it is then dried over a current of heated air. If no imperfections are detected on examination, it may next be submitted to the action of a reagent, which will etch the copper on the exposed lines without affecting the silver. Solutions of perchloride of iron, persulphate of iron, and nitrate of silver are found suitable for this purpose. The first is perhaps preferable, though it is more apt to corrode the lights than the last. The objection to this is its tendency to fill up the fine lines by deposition of metallic silver. The aqueous solution of the perchloride should be of the strength repre-

sented by a lemon-yellow color. "The plate is to be immersed in a horizontal position, with the face up in the solvent, and a soft camel's hair pencil swept gently over it from time to time. In the course of 30 minutes or less, the action of the perchloride will have thrown up chloride of silver, so that the brush can sweep it away, and the light copper will appear in the bottoms of the lines. The plate may then be washed and dried, and if on inspection it should not be thought deep enough to hold the ink for printing, it may be returned to the bath of perchloride for a short time." The difficulty in the process has been to obtain sufficient depth in the lines without corroding the lights; and the maps consequently, though exact copies, lacked force of expression. The engraver, however, can soon remedy this by going over the lines upon the plate with the burin, and thus giving them the required depth. The film of silver over the copper is necessarily very thin in order that the first etching may reach through it, and yet it must be sufficiently thick to afford complete protection to the copper it is designed to cover. It has been a nice matter, thus restricted in both directions, to determine exactly the right thickness. In answer to some questions raised respecting the tendency of the biting agent to work laterally and produce rough and uneven lines, Mr. Mathiot presented a communication to "Humphrey's Photographic Journal," Nov. 15, 1855, in which he advances the opinion, based upon his experiments, that it is not the film of mercury which protects the light shades from the action of the reagents which corrode the darker parts; but that in the lights of the picture a crystallization of the silver has taken place, and this has extended within the metal in proportion to the intensity and duration of the light. The action appears to be directly due to the mercury, and the effect is to protect the metal in proportion as this crystallization has taken place, not merely at the surface, as it would be protected by a film, but also in the substance of the metal; so that the lines made by etching a daguerreotype do not spread at the bottom. On the contrary, from the crystallization spreading in the interior under the shaded portions, the lines become narrower as they grow deeper. In the "Coast Survey Reports" of 1855 and 1857 are accounts of the extraordinary improvements of Mr. Mathiot in the application of the electrotpe to the engraving of charts. In the former year he devised a method of joining together detached plates to make a single large one, without incurring the tedious and somewhat hazardous operation of fitting the thick plates by sawing or filing their edges to the required shape. Instead of this he took thin electrotpe casts of the detached plates, trimmed these with scissors to fit each other, and cemented them with shoemaker's wax upon a blank plate; the wax in excess he wiped off with a cloth saturated with oil of turpentine. The plate is then ready for the electrotypist. By this method work which required

weeks of mechanical labor is completed in as many hours by the artist himself, and no risk is incurred of injuring the plates. Large maps also can be rapidly engraved by dividing the work among many engravers, and taking separate electrotpe casts of each piece to be afterward united in one. In the report of 1857, printed in 1859, the extraordinary progress in this department is more particularly noticed, and the fruits are seen in the great number of beautifully engraved charts which accompany the report. A new plate is prepared on an average in every 2½ working days, when a few years ago it was thought an achievement to produce 6 in a year. Thin electrotypes serve even to print from, being made sufficiently stiff by stretching them on smooth steel plates, called stretch-plates—each one serving for all electrotypes of its size. Mr. Mathiot proposes this application to all kinds of printing done from engraved surfaces other than warped surfaces. Mr. Mathiot reports as follows: "The working of the thin electrotypes has suggested to me the idea of using these plates on a circular bed or roller, and gaining thereby the great advantages of cylinder printing for flat plates. This has often been sought before, but the impossibility of getting a rigid plate to conform accurately to a cylindrical figure has hitherto defeated it. As the thin electrotypes are easily strained over a curved surface, the great desideratum is now attainable. I am about having this matter put to a practical test, and have every hope that the copperplate printing can thus be executed by steam machinery, and with almost the rapidity of letterpress work."—As applied to stone, the art is now known as photo-lithography, and maps thus prepared were first published in the 1st volume of Palfrey's "History of New England" (Boston, 1859); and others in the same style were next seen in Lesley's "Iron Manufacturer's Guide" (New York, 1859). For an account of the process see LITHOGRAPHY. Applied to wood, the art is called xylo-photography. By one of the various methods proposed, the block is covered from the light of day with a mixture of oxalate of silver, water, and a little gum. This is rubbed with the finger till the moisture nearly disappears, and a delicate coating of the silver salt is evenly spread upon the wood. The block is then put away in the dark for any length of time; and when wanted, it is ready to receive the picture by the usual photographic process as applied to prepared paper. This being done, the block may be immediately engraved, just as if the picture had been transferred by ordinary methods, except that it should not be exposed to the direct rays of the sun, nor so long as several hours to diffused daylight. The chief difficulty experienced in these transfers is the liability of the chemically prepared surface to flake off on touching the block with the graver. In the *Comptes rendus*, Oct. 1857, is a description of another process in which the wood is coated with alum, gelatine, and animal soap, then exposed to a solution of

sal ammoniac, and after this to one of nitrate of silver. The picture is transferred from another on glass or paper, and is fixed by a saturated solution of hyposulphate of soda. The following process was devised in Worcester, Mass.: A preparation is applied to the blocks of asphaltum dissolved in ether, as M. Niepc de St. Victor used the same in photo-lithographing. This is followed by an application of lampblack. The surface is then polished with a smooth cushion, till it becomes of glossy jet black, when it is coated with collodion and rendered sensitive by nitrate of silver. It is then ready for the camera. Herr Pretsch in 1856 devised a new method applicable to copperplate engraving, in which the electrotpe process was applied to succeed the photographing. He exposes a glass or metallic plate, coated with a mixture of glue, bichromate of potash, nitrate of silver, and iodine of potassium, to the copying process with the design to be transferred. A faint picture is produced upon the prepared surface. After washing, the picture comes out in relief by the swelling of the film. It is then subjected to other processes, which raise it still more and increase its hardness. It may then be made to receive by the electrotpe operation a coating of copper; or it may first be transferred by pressure to a warm sheet of gutta percha, and this be subjected to the copper solution in the battery. This process excited great expectations, and in England a company was formed to engage in the operation upon a large scale. It did not, however, prove a profitable undertaking. Another invention, called photo-glyphic engraving, has recently been patented in England by Mr. Fox Talbot, distinguished for his early researches and discoveries in photography. It is applicable to plates of steel, copper, or zinc. He obtains upon the plate a faint image of the object to be copied by the process patented by him in 1852, using a coating of glue and bichromate of potash. But he avoids the subsequent washing then employed. Instead of this he covers the plate evenly with a thin coating of finely powdered gum copal, and melts it over a spirit lamp, thus producing a uniform aquatint ground, ready for etching. A small quantity of saturated solution of perchloride of iron, with the addition of about $\frac{1}{2}$ its quantity of water, is poured on the plate and spread with a camel's hair brush. This liquid penetrates the gelatine only where the light has not acted on it. In about a minute the etching is seen to begin, which is known by the parts etched turning brown or black, and then it spreads over the whole plate, completing the operation in all the details of the picture in 2 or 3 minutes. The action is assisted by stirring the liquid all the time with the brush, and thus gently rubbing the gelatine. To deepen any portions, the brush may afterward be applied with fresh liquid, but prepared of equal parts water and saturated solution of the iron salt. The weak solution is said to act more rapidly than the stronger.—

BANK NOTE ENGRAVING. To the efforts of artists and mechanics in the various processes of manufacturing bank notes the art of engraving owes some of its most important developments. In the United States this branch has attained its greatest perfection, and whatever skill has in England been shown in bank note engraving has been the result of improvements introduced directly from this country. The rude and cheap notes, roughly engraved, such as were used by the bank of England a century and a half ago, were reproduced unaltered for at least 100 years, at the expiration of which it was found necessary to effect some improvement because of the frequent forgeries detected about that time. In the year 1800 the directors of the bank of England first endeavored to furnish notes which should be secure from counterfeits, but this attempt failed. Forgeries multiplied, and it was not until 1820, two years after a committee had been appointed by the society for the encouragement of arts, and commissioners had been appointed by the English government for the purpose, that any positive improvement was made in the style of engraving bank notes. In America, however, a superior system had for some years existed. The continental notes, the earliest in this country, engraved by Harrison, were of no importance as works of art, and those next engraved for the bank of North America, by the Philadelphia firm of Murray, Draper, and Fairman, were little better; but the invention of steel plate engraving and the transferring process by Mr. Jacob Perkins, described in a previous part of this article, at once raised bank note engraving to the rank of a special art. Mr. Perkins's reputation as a manufacturer of bank note plates became so great that in 1808 a peculiar style of note with stereotype check, invented by him, was by a special law of Massachusetts directed to be used for all the banks of the commonwealth. This "stereotype check plate," although a sufficiently thorough protection against counterfeiting at the time of its adoption, grew so familiar in the course of 20 years that fraudulent imitations became numerous, and the law was ultimately repealed. Some New England banks continue to use it to this day, notwithstanding the inelegance of its appearance compared with what more modern engravers have accomplished. About 1814 Mr. Perkins went to Philadelphia, and became associated with the firm of Murray, Draper, and Fairman, with whom he remained several years, still perfecting his machinery. He left behind the original transfer press constructed by him, which is still at Newburyport, though long ago discarded as too clumsy and complicated for use. The first piece of steel on which transferring experiments were made by him is retained in the Boston office of the "American Bank Note Company" as an interesting relic. While Mr. Perkins was in Philadelphia, Asa Spencer, also connected with Murray, Draper, and Fairman, succeeded in applying the mechanism of lathe work to bank notes, thereby secur-

ing a new, and at that time impenetrable, defence against counterfeiting. This adaptation of the "geometric lathe," although but the new application of an old principle, was nevertheless so successfully employed by Mr. Spencer that he justly received as high credit as if he were the original inventor. The peculiar advantage of lathe work in bank note engraving will be spoken of in the description of the different processes hereafter. The first lathe machine made by Mr. Spencer is now in the possession of Cyrus Durand in New York. In 1818 Mr. Perkins, attracted by the liberal propositions for competition offered by the bank of England, went to London, accompanied by Mr. Fairman and a number of experienced workmen. The superiority of Mr. Perkins's work was immediately perceived, but not so readily acknowledged; and unfortunately for his prospects, a London wood engraver, Mr. Darton, succeeded after many efforts in making a woodcut copy of one of his pieces of lathe work, a circumstance which was used as so powerful an argument against the American competitor that he was obliged to withdraw from the contest, and the privilege of manufacturing their notes was awarded by the bank to Messrs. Applegarth and Cowper, in 1820. But so confident was Mr. Perkins in the security of his notes, that soon after, when supplying a bank in Ireland, he voluntarily agreed, if they should be forged, to furnish a new issue without charge. Mr. Fairman and the other Americans returned home not long after, leaving Mr. Perkins, who established a partnership with Mr. Heath, an eminent engraver of London, which lasted during his life. Mr. Perkins's improvements have extended throughout England, and have been used on the continent, though in a comparatively small degree, as bank notes are there generally engraved upon a different and less complicated, as well as less artistic plan. In the United States the rapid increase of banks occasioned a demand for variety and beauty in notes almost insatiable. Bank note engraving companies were formed in various parts of the Union, but never became very numerous in consequence of the large amount of capital required to carry on this business, and more especially the difficulty of procuring first rate artists and mechanics. For a long time the business was immensely profitable, and indeed has remained so to the present, excepting when excessive competition has greatly lowered the prices. In 1857 there were 5 or 6 principal companies in the United States, most of which extended their operations by branch houses in every direction; but in May, 1858, all the important companies were united in one general organization, under the title of "The American Bank Note Company." This company now performs nearly all the bank note engraving and printing required in North and South America. It is admirably administered, and its operations are so thoroughly systematized, that the chances of extensive counterfeiting of its notes, or of alteration of notes of a low denomination to those of greater

value, are very small. It should, however, be understood that it is impossible to interpose a completely effectual preventive against counterfeiting. Whatever can be done can be repeated. Each bank note legitimately produced can be fraudulently imitated with such similarity as to deceive even the most practised eye. But by the employment of the highest capabilities of the art, and by securing the services of the finest workmen, it is also possible to keep so far in advance of what the less skilful forgers can hope to do, that the danger need never be great provided proper care be exercised by the public itself. It is the anxiety on the part of bank note companies to prevent counterfeiting by availing themselves of the best talents, and employing every artistic expedient, as well as the desire to obtain patronage by the production of attractive notes, that has contributed to raise the standard of bank note engraving in this country to its present elevation. Some of the names most distinguished in connection with this subject have already been mentioned. Prominent in the development of the art since the time of Perkins and Spencer were J. W. Casilear and James Smillie. The former excelled as a designer and in the vigorous and masterly use of the graver, whose capabilities he would seem almost to have exhausted; the latter became eminent for the exquisite delicacy of his etchings, and although he never confined himself to bank note work, yet his engravings have been a standard guide to all students. Among those who have combined the various requirements of the art, possessing equally intimate acquaintance with its minute details and its higher attainments, Timothy House is considered foremost. The works of these artists have adorned a large proportion of the bank notes which have been circulated for the past 25 years, and their superiors, altogether considered, have not yet appeared.—We have now to say a few words of the actual processes of bank note engraving, as it is carried on in the United States; for here alone is it seen in perfection. The present bank of England notes are, for example, printed from an electrotype surface, as wood engravings are; a system fatal to all delicacy in the work, although possessing the advantages of speed and cheapness. According to this system, introduced by Mr. Smee, in 1855, the original engravings of the various portions of the note are not printed from directly, but are used as moulds from which electro-casts are taken; the notes are then printed upon a steam press from these electrotypes. The notes of the bank of France are also printed from a surface, although in a neater and more elegant manner than in England. The American bank note engraver confines himself to line engraving; the stipple, mezzotint, aquatint, and other varieties not being sufficiently distinct or delicate to be of service to him. In order to prevent as far as possible attempts at imitation, it is necessary to produce the most elaborately fine engravings; and for additional security, sections of bank

note decorations are cut by machinery with an exquisite minuteness which could not be accomplished by hand. The pictorial portions of the modern bank note are the vignette or centre piece, usually placed near the middle, at the top, the end pieces, and the tail piece at the bottom. The arrangement of these varies according to the taste of the bank note designer, and their positions are often reversed. The counters, on which are fixed the denomination numbers, 1, 2, 3, 5, &c., are of intricate lathe work, and generally, though not necessarily, occupy the upper corners, for the sake of convenience in counting. The pictures are originally engraved on separate small plates, and are thence transferred to the bank note plates by the process invented by Mr. Perkins. The small plate is softened, and thoroughly annealed before passing into the engraver's hands. After his work is done, it is hardened by restoring its carbon, and the whole engraving transferred to new plates as desired. The average cost of engraving a vignette of ordinary size is \$125; an end piece or portrait costs about \$75; and a tail piece about \$20. By the aid of the transferring process, bank note companies are able to furnish a steel note plate for \$125, which otherwise, as it appears, would cost \$800 for pictorial engraving alone, leaving out of question the machine work and the letter engraving. The time required to engrave a vignette varies from one to two months. A transfer can be effected in 15 minutes or less. The counters of notes are cut by the lathe machine, as improved by Mr. Spencer, in every form of intricate and involved regularity. They cannot be imitated except by similar machines, which it is not in the power of counterfeiters to easily procure, or even to use successfully. Sometimes lathe-work counters are drawn with a diamond point upon a plate covered with etching ground, and bitten in with acids; and again counters have been produced by medallion rulings, also bitten in; but both of these processes, having been found inferior to the first, have been almost entirely discontinued. After the lathe-work patterns have been cut upon soft steel, the large figures of denomination are cut over them by the letter engraver, and the plates are hardened, to be transferred. It is seen that thus the principal work of manufacturing bank note plates is done by the transferring press, and in most cases even the lettering, titles, dates, &c., are similarly stamped. Bank note companies have always on hand a large assorted stock of engravings, ready to be transferred in every variety of combination. Sometimes, for additional security, a bank requires one or more special engravings, for which it pays, retaining the exclusive right to use them. The expense of a set of plates, for a bank of ordinary capital and business, ranges from \$900 to \$1,200. Notes are usually arranged 4, 3, or 2 together, upon large thin plates of steel; but are sometimes, to facilitate the printing, put upon separate thick blocks. For the notes of low denominations, 1, 2, 3, 5, 10 and 20, steel is always used, so that the

large number of impressions needed may be obtained without great difficulty. Twenty thousand notes can be printed from a steel bank note plate, and by retouching and retransferring it may be so restored as to yield almost as many more. The 50, 100, 500, and 1,000 dollar notes, of which fewer are needed, are sometimes put upon copper, which will give only about 3,000 impressions. For a single steel plate \$125 is charged; for a copper plate, \$75. Until recently, banks were able to procure notes at a cheaper rate by means of a "general plate," which was so constructed that any required title could be inserted in an otherwise unalterable block. By this plan many banks circulated notes precisely alike, with the single difference of the name of the bank; and thus offered decided advantages to counterfeiters, which were systematically made use of. But the "general plate" system has been put aside by the "American Bank Note Company," and is not likely to be revived. Plates for bank checks, drafts, certificates of stock, &c., are frequently engraved in the same manner as notes.—The printing of bank notes is a labor demanding extreme care at every step. The ink must be nicely ground and mixed, and of the finest quality. The paper needs to be wetted with exact regularity. The best workmen can hardly print more than 600 impressions in a day, whereas by the coarser electrotpe process of the bank of England, in which any number of duplicate plates may be used, it is customary to throw off 3,000 in an hour. After printing, the sheets are laid away to dry for 2 or 3 weeks, and are then put between pasteboards, and smoothed by a heavy hydraulic pressure. Sometimes a high polish is imparted by pressing the notes between hot steel plates, but this destroys the strength of the paper. As the principal aim of banks is to protect their notes as thoroughly as may be from counterfeits and alterations, many expedients in printing have been devised to that end. One of these is the application of large letters and figures in red, printed from types, on the back as well as the face of the note. For some years this plan was very generally resorted to, though it was known to be theoretically imperfect, and of little real value. A more recent device is that of covering the paper before the note has been printed with a colored tint, communicated from a plate of fine and faint lathe work. The special object here is to prevent, not counterfeit engraving, but copying by photography, which has come to be considered the greatest danger to which bank notes are exposed. The American association for the advancement of science, in its meeting at Montreal, in 1857, discussed at length this subject of photographic reproduction of bank notes, but threw no light upon it. It is understood that photography cannot communicate colors, but unfortunately no tint has yet been discovered which may not be chemically removed from the paper. The tint once removed, the photographing of the black body of the note, which is suffered to remain, may of course be effected, and

the color subsequently restored with a brush or otherwise. It is doubted by chemists whether any positive preventive against photographic counterfeiting can be provided; but by certain appliances, notes may be so prepared that imitations must be immensely difficult and expensive, and only to be accomplished by first class artists and mechanics. The expense of printing plain bank notes is \$2 50 per hundred sheets, each sheet containing 4 notes. The charge is greater when colors are applied, according to the nature of the application. (For ENGRAVING on precious stones, see GEM).

ENNEMOSER, JOSEPH, a German physiologist, born in Tyrol, Nov. 15, 1787, died in Egern, Upper Bavaria, Sept. 19, 1854. In early life he was a shepherd, but having attended the school of his village, his love of learning induced several clergymen to send him to a gymnasium and afterward to the university of Innsbruck. Among his classmates was the celebrated Hofer, whom he followed to the revolutionary war as secretary. He won distinction in the campaigns of 1813 and 1814, resumed his studies after the restoration of peace, was graduated as doctor of medicine in Berlin in 1816, officiated from 1819 to 1837 as professor in Bonn, afterward practised his profession at Innsbruck, and in 1841 removed to Munich, where he gained a high reputation for his skill in the practical application of animal magnetism and for his writings on medical and physiological science. His most important works are: *Der Magnetismus* (2d ed., Leipsic, 1844; translated into English by William Howitt, under the title of "Natural History of Magic," 2 vols. 12mo., London, 1854); *Der Magnetismus im Verhältniss zur Natur und Religion* (2d ed., Tübingen, 1853).

ENNIS, a parliamentary and municipal borough and market town of Ireland, capital of the county of Clare, on the river Fergus, 112 m. W. S. W. from Dublin; pop. in 1851, 7,840. It is irregularly built, and the ruins of an ancient Franciscan abbey, founded in 1240, are its only noticeable architectural feature. It has 3 bridges across the Fergus, manufactories of linen and flannel, and considerable trade in agricultural produce. The borough returns one member to the house of commons.

ENNIUS, QUINTUS, the father of Roman literature, born in Rudiae, a village of Calabria, 239 B. C., died 169. He claimed descent from a mythical hero, the first settler in his country, and in later life, after he had learned the Pythagorean doctrine of transmigration, he boasted that the soul of Homer dwelt in him. Nothing is known of his life till at the age of 38 years he appears as a soldier in the Roman army, enjoying the friendship of the elder Cato, by whom he was taken to Rome. There he taught Greek and Latin, but seems to have held no marked position till in 189 he made the Ætolian campaign under Fulvius Nobilior, gained the acquaintance and esteem of the elder Scipio and the most considerable Romans, and received the rights of Roman citizenship. From this time

his learning and the charm of his conversation attracted to his little dwelling on Mount Aventinus the most enlightened citizens. Chronological reasons make it improbable that he was the instructor of the elder Cato in Greek, as was afterward asserted. His contemporaries marvelled at his learning, which in thoroughness and extent was surpassed by few of the later Romans. Though a master of Greek literature, he gave a thoroughly national character to his own works. The principal of these, entitled *Annales*, was a poem upon Roman history, which he treated consecutively from Romulus and Remus to his own times, describing later events with the greater fulness. This poem was popularly admired, and was the chief foundation of his fame. Its poetical merits were such that Virgil did not disdain in many places to imitate it, and as a history its value would be great to us; but though it appears to have existed in the 13th century, nothing but fragments of it gathered from the ancient writers now remain. These are sufficient to show that Ennius devoted great attention to his language, and contributed much in harmonizing and perfecting the yet rough and uncultivated Latin dialect. Ennius also wrote both tragedies and comedies, and adapted the masterpieces of Æschylus, Sophocles, and Euripides to the Roman stage. Among his numerous short pieces, his epigrams, 3 of which, extending collectively to 10 lines, have been preserved, were especially famous. The best collection of the fragments of Ennius is by Hesselius (4to. Amsterdam, 1707).

ENNS, or ENX (anc. *Anisus*, or *Ancus*), a river of Austria, rises in the circle of Salzburg, on the northern slope of a branch of the Noric Alps, 12 m. S. of Radstadt, flows N. past that town, then E. N. E. through Styria, then N. separating the provinces of Upper and Lower Austria, and after a total course of 170 m. entering the Danube 2 m. below the town of Enns. Its principal affluents are the Steyer on the right, and the Salza on the left. It is navigable to Riefing, and its upper part lies amid wild mountain scenery. The archduchies of Upper and Lower Austria are often called the provinces of the Enns, or Upper and Lower Enns.

ENNS, a town near the junction of the river Enns with the Danube, with manufactories of iron, steel, and cotton goods; pop. 8,500. A battle between the French and Austrians took place there, Nov. 5, 1805. Adjoining the town is the old castle of Ennseck.

ENOCII, the son of Jared, and father of Methusaleh, born, according to the Biblical chronology, A. M. 622. He is called "the seventh from Adam" (Jude 14), to distinguish him from Enoch the son of Cain, who was only the third from Adam. Eusebius infers from the title of "father of astronomy," given him by an old writer, that he is the same whom the Greeks worshipped under the name of Atlas. We read in the Scriptures that "he walked with God," and "pleased him." And as to his departure from the world, we are told, that "he was not,

for God took him;" i. e., that in his case, as in that of Elijah, the body without suffering ordinary dissolution was clothed with immortality, or endued with the immortal principle by the immediate power of God. The character of Enoch is drawn by two apostles (Heb. xi. 5, 13, and Jude 14, 15). The last passage has been the subject of much controversy, referring as it does to a prophecy by Enoch, some portions of which it cites apparently in the language of the prophet himself. A prophetic work called the "Book of Enoch" is frequently mentioned in the writings of the fathers. It is noticed by Justin Martyr, Irenæus, Clement of Alexandria, Tertullian, Origen, Augustine, Jerome, Hilary, and Eusebius. Most of these considered it apocryphal, though Tertullian maintained its authenticity and defended it from the criticisms of his contemporaries. Bruce, the traveller, brought home from Abyssinia 3 copies of the book in the Ethiopic language, which immediately excited great interest in Europe. The eminent orientalist De Sacy translated some portions of it, and a complete English version by Dr. Laurence, professor of Hebrew at Oxford, appeared in 1826. In 1833 a second, and in 1838, a third revised edition appeared. The book is supposed to have been originally composed about the time of the Christian era, in the Hebrew or Chaldean language. The Ethiopic version, however, was not made from the Hebrew, but from a Greek translation which is not now extant.

ENSIGN (Lat. *insigne*, a standard), in ancient warfare, a banner designed to communicate telegraphic signals rather than to be a centre for rallying. Near the end of the middle ages, it was a secondary color borne after the national banner or the pennon of the general. Macchiavelli regrets that in his time ensigns had become of little use, and were merely the furniture of parades. Subsequently the name was given to the colors of infantry, and also to the bearer of the colors, who was the first sergeant. Still later the colors were borne by cadets, who were in the line of promotion to lieutenantcies; but the function afterward returned to the ensign. The grade of ensign is still retained in the English, Prussian, and Austrian armies, but the word no longer designates the colors of infantry or the standards and guidons of cavalry. The Prussian ensign is not an officer, and the English ensign is thus designated without necessary reference to the colors. His duties are those of a subaltern officer.—In naval language, the ensign is the banner or flag hoisted on a long pole, over the poop, called the ensign staff. The ensign is also the lowest of the officers of the French navy, and has the rank of a first lieutenant of artillery, but the flag is not specially intrusted to him.

ENTABLATURE (Lat. *tabulatum*, a stage or story), in architecture, the horizontal continuous work which is supported by the columns. It has 8 principal divisions: the architrave, which rests upon the capitals of the columns, the frieze immediately above it, and the cornice

at the summit. The height of the entablature, according to the most commonly received opinion, ought to be generally two diameters of the column, but it varies somewhat in different orders; in the temple of Minerva at Athens, one of the purest examples known of the Grecian Doric style, it is almost exactly two diameters.—The term entablature or entablement is also applied to the last course of masonry on a wall, immediately under the roof.

ENTAIL, an expression used in the old books for an estate in tail (medieval Lat. *feodum talliatum*, from *taliare*, to cut off), signifying a truncated inheritance, as being carved out from a larger estate, or perhaps from the exclusion of certain heirs. For the nature of this species of inheritance, see ESTATE.

ENTERITIS (Gr. *εντερον*, an intestine), a medical term denoting acute inflammation of the external or peritoneal coat of the intestines, as distinct from inflammation of the mucous coat. This is a painful and dangerous disease, and not unfrequently terminates in gangrene in a few hours from the first attack. Its symptoms, which can seldom be mistaken for those of any other complaint except colic, with which it is closely allied, and which indeed is apt to originate it, are fever, frequently preceded by chilliness, fixed pain in the abdomen, costiveness, and in most cases vomiting. The pain is restricted to a small part of the abdomen, or spreads over its whole surface, according as the inflammation extends to the whole or part of the intestines; it is commonly severest about the navel, and is always increased by pressure. This pain is generally the first manifestation of the disease. As it becomes more intense the bowels seem drawn together by a kind of spasm, the features grow sharp and compressed, and afterward, if the attack be very severe, are much sunken, giving the countenance a wild and fearful expression. The brain usually but not always remains unaffected. The causes of this disease are acrid and indigestible substances taken into the stomach in large quantities, indurated feces, high living, long continued costiveness, strangulated hernia, spasmodic colic, the involution of one fold of the intestine within another, application of cold to the belly or the extremities, and cold drinks when the body has been previously over-heated. It attacks persons of every age, from childhood to the most advanced period of life, but old persons are most subject to it.

ENTOMOLOGY (Gr. *εντομον*, insect, and *λογος*, discourse), the branch of natural history which treats of insects, one of the classes of articulated animals. That part of the science which refers to the anatomy and physiology of the class will be treated under the head of INSECTS; and the particular descriptions of orders, families, genera, and species will be found under their various scientific and popular titles. This article will be devoted to the history of entomology, and to brief sketches of the principal systems of classification. In entomology, more

perhaps than in any other department of natural history, does the student feel the want of a natural classification; but, as the best authors have devoted very unequal study to different groups, from the impossibility of fully cultivating every portion of the immense field, no classification complete and natural in all its parts can be found; the second Cuvier is yet to arise who shall form from the scattered though admirable fragments a truly natural system of entomology. The descriptive portion of the science is as yet very incomplete; when we consider the great number of known species, and the small size of most of these in carefully studied districts, and our comparative ignorance of the insects of foreign countries, it must be confessed that the nearly 100,000 species now described probably do not form one-half of the total number in existence. If we take for a basis the comparative ratio which has been found to exist in Germany between insects and plants, that of 2 to 1, and extend this to the whole world, we should have in round numbers at least 400,000 species of insects inhabiting the earth.—It appears that Aristotle, the father of natural history, separated insects from crustacea, and divided them into winged and wingless, subdividing these last into several natural minor groups so successfully as to excite the surprise and admiration of modern observers. From Aristotle we may pass over a period of 1,800 years, a blank as far as the progress of natural history is concerned, to the middle of the 16th century, when Gesner, a Swiss, revived the study of animals, leaving valuable papers on insects from personal observation, which were published after his death by Mouffet, in 1634. During the next 100 years Aldrovandus divided insects into 2 chief groups, land and water insects, subdividing them according to the structure of their wings and legs; Hoefnagel made beautiful figures of them; Redi studied their origin and mode of propagation; Malpighi made a careful dissection of the silkworm; Goedart and Valisnieri described the metamorphoses of insects; Leeuwenhoek examined them microscopically; and Madame Mérian studied the development of the lepidoptera, going to Surinam in her scientific zeal to continue her observations among the most gorgeous species. The writings of Swammerdam, a Dutch naturalist in the middle of the 17th century, created a new epoch in the annals of entomology. He studied the metamorphoses of insects, and from these introduced the first attempts toward a natural classification. His system was as follows: I. Insects without a metamorphosis, changing their skin but not their form, as spiders, lice, wood lice, and myriapods. II. Insects with a metamorphosis: a, those moving in all stages of existence, at first wingless, then with rudimentary and finally with entire wings, including what are now called *neuroptera*, *orthoptera*, and *hemiptera*; b, motionless in the pupa state, but having limbs, including the *hymenoptera*, *coleoptera*, and *lepidoptera*; c, ovate pupæ, wingless

and motionless, as the *diptera*.—John Ray, an English clergyman living in the latter part of the 17th century, was the first true systematist, and doubtless furnished Linnæus with many of the ideas afterward successfully worked out by him. In a "History of Insects," published after his death in 1705, is the following arrangement: I. Insects without metamorphosis, including: 1, *apoda* (annulate worms), terrestrial and aquatic; 2, *pedata*, including the terrestrial (lice) and aquatic hexapods, the octopods (spiders), lobsters and crabs, the terrestrial polypods (centipedes and wood lice), and the aquatic polypods (*amphipoda* and *isopoda* of Latreille). II. Insects with metamorphosis, including: 1, those with moving larvæ and pupæ (*orthoptera* and *hemiptera*); and 2, those with motionless pupæ, as *coleoptera*, *lepidoptera*, *diptera*, and *hymenoptera*. III. Insects with simple metamorphosis, moving through most of the stages, like the dragon-flies.—Réaumur, in the middle of the 18th century, published his *Mémoires pour servir à l'histoire des insectes*, affording valuable information on the habits of insects, but wanting in systematic arrangement. About the same time, in 1735, appeared the *Systema Naturæ* of Linnæus, who displayed in the classification of insects the same intuitive perception of the characters of groups that is observable in his other branches of the animal kingdom. His system is based on the characters of the wings and the presence or absence of a sting; as follows: I. Insects with 4 wings, including the following orders: 1, *coleoptera*, with the anterior wings crustaceous, with a straight suture; 2, *hemiptera*, with semicrustaceous incumbent anterior wings; 3, *lepidoptera*, with all the wings covered with scales; 4, *neuroptera*, with all the wings membranous, and with no sting in the tail; 5, *hymenoptera*, with membranous wings and tail armed with a sting. II. Insects with 2 wings, comprising: 6, *diptera*, with poisers in place of the posterior pair. III. Insects with neither wings nor clytra, including: 7, *aptera*, in which were placed by Linnæus the hexapod lice, fleas, &c., spiders, crabs, and centipedes. The fault of this system is its exclusive principle of division drawn from the wings, which placed among the *aptera* animals far removed from insects proper.—De Geer, a Swede, published a work on insects between 1752 and 1778, having the same title as that of Réaumur, of which it may in some respects be considered the sequel; his system is intermediate between that of Linnæus and that of Fabricius, who came after him, being based both upon the organs of flight and those of manducation, and according to Mr. Kirby is more natural than that of either of the above-named naturalists. It is as follows: I. Insects with wings, *alata*, including: A. *Gymnoptera*, or those with 4 wings without cases, with the subdivisions: 1, *lepidoptera*, with scaly wings and spiral tongue; 2, *clingula*, with naked membranous wings, no teeth nor tongue (*trichoptera*, *ephemerina*); 3, *neuroptera*, with membranous, equal, reticulated wings, and teeth

in the mouth (as *libellula* and other Linnæan *neuroptera*); 4, *hymenoptera*, with membranous unequal wings, teeth in the mouth, and a sting or borer in the females; 5, *siphonata*, with membranous wings and tongue bent beneath the breast (*homoptera* of Leach), including the *aphides* and *cicada*. B. *Vaginata*, or those with 2 wings covered by elytra, with the subdivisions: 6, *dermaptera*, with elytra half coriaceous and half membranous, crossed, a pair of membranous wings, and tongue bent beneath the breast (*hemiptera* of Leach), as the bugs and water bugs; 7, *orthoptera*, cockroaches and grasshoppers; 8, with teeth in the mouth, and the wings of beetles (*coleoptera*). C. *Diptera*, with 2 uncovered wings, including: 9, *halterata* (the *diptera* of Linnæus), having a pair of poisers, mouth with a tongue without teeth; 10, *proboscidea* (like the genus *coccus*), with no poisers, tongue, or teeth in the male, and no wings, but a tongue in the breast of the female. II. Insects without wings, *aptera*, including: D. *Saltatoria*, with the subdivision: 11, *suctoria* (*culex*), undergoing metamorphosis, with 6 legs, and mouth with tongue, the *aphaniptera* of Kirby. E. *Gressoria*, with the subdivisions: 12, *aucenata*, undergoing no metamorphosis, with 6 legs, and head and trunk distinct, as *termes*, *pediculus*, *psocus*; 13, *atrachelia*, spiders and crabs; 14, *crustacea*, as

isopods, amphipods, and myriapods. This system, though not purely artificial, and founded on several correct principles, is yet far from natural, and includes among insects animals which do not belong with them; his 14 orders comprised only about 1,500 species referable to 100 genera.—Geoffroy, in France, in 1764, published a system which is important from the introduction of the joints of the tarsi as a means of classification; he makes only 6 groups, *coleoptera*, *hemiptera*, *lepidoptera*, *tetraptera*, *diptera*, and *aptera*, the 3d, 5th, and 6th being the same as the Linnæan; it is an exceedingly unnatural system.—Fabricius, a German, a pupil of Linnæus, introduced important improvements into the science during the last quarter of the 18th and the beginning of the 19th century; his system is based upon the number, proportions, form, and situation of the parts which constitute the mouth, without regard to other parts of the insect; by building upon this narrow foundation he departed widely from nature, though by drawing attention to the maxillary system he has enabled his successors to define certain groups with considerable accuracy. His first classification of 1775 was greatly modified in the course of his life, and the following was proposed by him in his *Entomologia* in 1798:

I. INSECTS WITH BITING MOUTHS.

A. Two pairs of mandibles.

a. The lower ones having palpi.

1. Free without covering.
2. Covered.
3. Connate with the labium.
4. Distended, thin, coriaceous.
5. Horny, strongly toothed, labium without palpi.

b. All without palpi.

B. A pair of scissor-like maxillæ.

C. More than 2 pairs of maxillæ.

1. Within the labium.
2. Outside the lip, closing the mouth.
3. Outside the lip, but covered by the palpi.

1. Class *elautherata* (beetles).
2. " *ulonata* (*orthoptera*).
3. " *synistata* (*neuroptera*).
4. " *piasata* (*hymenoptera*).
5. " *odonata* (*libellula*).
6. " *mitosata* (*scolopendra*).
7. " *unogata* (scorpions and spiders).
8. " *polygonata* (*isopoda*).
9. " *pleistagnatha* (short-tailed crabs).
10. " *exochmata* (long-tailed crabs).

II. INSECTS WITH SUCTORIAL MOUTHS.

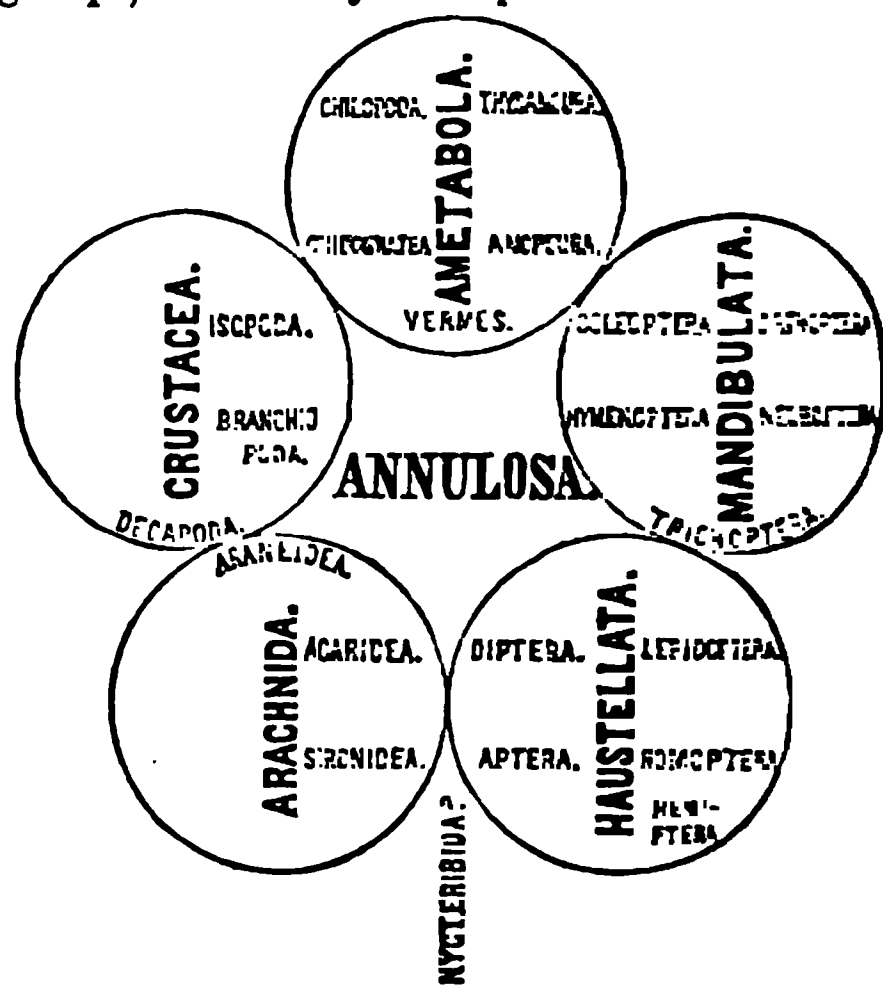

1. In the mouth a spiral tongue.
2. A horny proboscis, with jointed sheaths.
3. A soft, unjointed proboscis.
11. Class *glossata* (*lepidoptera*).
12. " *rhyngota* (*hemiptera*).
13. " *antliata* (*diptera*).

The facility with which genera were determined by this system secured for it many followers, in spite of its unnaturalness; and Illiger, by uniting it with that of Linnæus, considerably improved it. He made order 1 of Linnæus correspond with class 1 of Fabricius; 2 L. with 2 and 12 F.; 3 L. with 11 F.; 4 L. (to which were added *termes*, *lepisma*, and *podura*) with 3 and 5 F.; 5 L. with 4 F.; 6 L. (with *pediculus* and *acarus*) with 13 F.; and 7 L. (without the above-named apterous genera) with 6, 7, 8, 9, and 10 F.—Olivier, in the article *Insectes* in the *Encyclopédie méthodique*, follows chiefly the Linnæan classification, modified by Geoffroy and De Geer, making use of the wings and elytra, the parts of the mouth, and the joints of the tarsi, in his divisions; he substituted the term *orthoptera* for the *dermaptera* of De Geer; in his order *aptera* are still included spiders, crabs, and myriapods. In Olivier's great work on *coleoptera*, in 6 large quarto volumes with nearly 400 plates, published between 1789 and 1808, may be found the largest collection of

representations of this order yet known.—Latreille's first work, published in 1796, presents the insects of Linnæus in 14 classes, adding *orthoptera* to the Linnæan system, and separating the *aptera* into *suctoria*, *thysanoura*, *parasita*, *acephala*, *entomostraca*, *crustacea*, and *myriapoda*; this system, though in many respects unnatural, claims the positive merit of introducing some natural families. In 1810 he adopted a new classification, following Cuvier and De Lamarck in separating crustacea and arachnids from insects proper, and dividing the latter into the 7 orders of his 1st classification, adding the order *suctoria* (formed entirely by the genus *pulex*). In 1817 he added *myriapoda*, *thysanoura*, and *parasita* to his 8 orders, and also *strepsiptera* of Kirby; in 1825 he raised the *myriapoda*, after Leach, to a distinct class, and divided the *insecta* into 11 orders; in 1829 he reduced the *myriapoda* to an order among insects, raising the number again to 12 orders, and in 1832 raised them again to a class intermediate between arachnids and insects. One

great merit of Latreille is that he gave family names to the groups of genera, which Macleay has reduced to system by giving to them the termination *ida*, which, if not always classically correct, is of advantage for uniformity and euphony.—De Lamarck divided insects into 8 orders: I. Insects with suctorial mouths: 1, *aptera* (*suctoria*), Lat.; 2, *diptera*; 3, *hemiptera*; 4, *lepidoptera*. II. Insects with mandibulate mouths: 5, *hymenoptera*; 6, *neuroptera*; 7, *orthoptera*; and 8, *coleoptera*. Other *aptera* he placed among arachnids and crustacea, and ranked *thysanoura*, *myriapoda*, and *parasita* among arachnids.—Duméril places insects above mollusca in the animal series, and comprises among them arachnids and myriapods; his arrangement differs but little from the Linnæan; he endeavored to reunite the greatly divided families, and to reduce the number of genera.—Before passing to other classifications the philosophical systems of the modern German school may be alluded to; they proceed on the view that organic nature is one great whole, exhibiting progressive grades of development, which are characterized as classes. Oken has made 13 classes of animals, each represented by a successively added organ. Insects form the 9th class, and are called lung-animals; they are divided as follows: I. Germ flies, with perfect metamorphosis, with tribes: 1, *hemiptera*; 2, *orthoptera* and *dermaptera*; 3, *neuroptera*. II. Sexual flies, with perfect metamorphosis and equal wings, with tribes: 4, *diptera* and *suctoria*; 5, *hymenoptera*; 6, *lepidoptera*. III. Lung-flies, beetles, with perfect metamorphosis, elytra, and wings, with tribes: 7, *C. tetramera*; 8, *C. heteromera*; and 9, *C. pentamera*.—Among the English writers who have contributed to the advance of entomological classification, may be mentioned Leach, Kirby, and Macleay. Dr. W. E. Leach published several elaborate treatises on insects in the "Linnean Transactions," and in the British and foreign encyclopedias; his system is sketched in vol. iii. of the "Zoological Miscellany." He divides insects into *ametabola* and *metabola*, according to the absence or occurrence of metamorphosis, the 1st including 2 and the latter 14 orders; he subdivides *orthoptera* into 3 orders, adding *dermaptera* (*forficula*) and *dictyoptera*, and introduces also *omoptera* and *omaloptera*.—The classification of Kirby and Spence, as given in vol. iv. of the "Introduction to Entomology" (1815-'26), is as follows: I. *Mandibulata*, or insects with mandibles, containing the orders: 1, *coleoptera*; 2, *strepsiptera*; 3, *dermaptera*; 4, *orthoptera*; 5, *neuroptera*; and 6, *hymenoptera*. II. *Haustellata*, or insects with suctorial mouths, containing the orders: 7, *hemiptera*; 8, *trichoptera*; 9, *lepidoptera*; 10, *diptera*; 11, *aphaniptera*; and 12, *aptera* (all wingless insects breathing through tracheæ). It has been objected to this system that the 3d order is improperly separated from the 4th, and that the 8th forms naturally a part of the 5th. —The system of Macleay is founded on the fol-

lowing principles: 1, all natural groups return within themselves, and consequently present themselves in the form of circles; 2, each of these circles contains 5 others, connected in the same way; 3, where the circles join, there are intermediate groups connecting them more closely together; 4, the members of each, at the points where the circles meet, exhibit analogies. The animal kingdom consists of 5 circles, one of which, the *annulosa* (crustacea and insects), consists of 5 principal groups, which may be represented as follows:

The 3 orders of *ametabola*, *mandibulata*, and *haustellata* only concern us here. Of the 1st, the myriapods join the *crustacea*, and the *thysanoura* and *anoplura* (*parasita*) join the *mandibulata*. The *haustellata* and *mandibulata* he calls *insectaptilota*; the former include *lepidoptera*, *diptera*, *aptera* (*suctoria*, Latr.), *hemiptera*, and *homoptera*; the latter include *trichoptera*, *hymenoptera*, *coleoptera*, *orthoptera*, and *neuroptera*. These two circles are contiguous to each other in the *trichoptera* and *lepidoptera*, the genus *mystacides* (Latr.) of the former making the transition to *aglossa* (Latr.) of the latter. Space will not permit the introduction of the families which he considers the connecting links between the orders of the two great divisions. This system, while it has many forced and unnatural affinities, presents much that is valuable in determining the groups of transition, which are found among insects as among other branches of the animal kingdom. His principal work, *Horæ Entomologicae*, was published in 1819-'21.—Burmeister divides insects, according to the completeness of their metamorphosis, into *ametabola* and *metabola*, each group presenting both *haustellata* and *mandibulata*, and subdivided according to the form of the larva, the structure of the wings, and the internal organization. His system is as follows: I. *Insecta ametabola*, with imperfect metamorphosis: the larva, pupa, and perfect insect resembling each other, the pupa eating

and moving about: A. Having a suctorial mouth, with 4 fine setæ enclosed in a sheath, and the palpi wanting, with order 1, *hemiptera* (bugs). B. With a masticating mouth: *a*, with 4 unequal wings, anterior ones leathery, the posterior membranous and folded longitudinally and once transversely; prothorax free, and many biliary vessels; with order 2, *orthoptera* (locusts); *b*, with 4 generally equal wings, never folded, with order 3, *dictyoptera* (cockroaches). II. *Insecta metabola*, with perfect metamorphosis; the larva a worm, of 13 segments, with or without legs; the pupa motionless, or, if it moves, not eating. A. With suctorial mouth: *a*, with 2 naked transparent wings, the posterior replaced by pediculated knobs; 4 biliary vessels; larvæ without feet; soft proboscis, with several setæ and a pair of palpi; prothorax not free; with order 4, *diptera* (flies); *b*, with 4 wings, generally covered with scales, 6 biliary vessels; larvæ with feet and a distinct head; the maxillæ forming a spiral tongue; prothorax not free, but closely connected with the mesothorax; with order 5, *lepidoptera* (butterflies and moths). B. With masticating mouth, or at least visible mandibles and palpi: *a*, with 4 equally large or long wings, with reticulated nervures; rarely more than 8 biliary vessels; prothorax always free; with order 6, *neuroptera* (dragon flies); *b*, with 4 unequal wings, with variously branching nervures; larvæ generally without head or feet, yet sometimes with both; many biliary vessels; prothorax not free; with order 7, *hymenoptera* (bees, wasps); *c*, with 4 unequal wings, the anterior ones corneous; larvæ with head, with or without feet; 4 or 6 biliary vessels; prothorax always free; with order 8, *coleoptera* (beetles). In almost all these orders there are apterous families, genera, and species, whose place may be determined by their metamorphosis and the structure of the mouth; but they never form a distinct order like the *aptera* of Latreille. Burmeister maintains that all true insects undergo some metamorphosis, though in the apterous forms it may be difficult to detect it from the absence of the wings; as his idea of an insect necessitates metamorphosis, however imperfect, he gives the name *ametabola* (applied by Leach to apterous insects) to all those with an imperfect metamorphosis, as there is no real difference in the process of development in each.—Westwood, in his "Introduction to the Modern Classification of Insects," in 1839, gives the following:

I. MOUTH WITH JAWS.	II. MOUTH WITH A SUCKER.
Order <i>hymenoptera</i> .	Order <i>diptera</i> .
Osculant order, <i>strepsiptera</i> .	Osc. ord. <i>homaloptera</i> .
" <i>coleoptera</i> .	" <i>aphaniptera</i> .
Osc. ord. <i>euplexoptera</i> .	" } <i>heteroptera</i> (including the water bugs.)
" <i>orthoptera</i> .	" <i>homoptera</i> .
" <i>neuroptera</i> .	" <i>lepidoptera</i> .
" <i>trichoptera</i> .	

Stephens, in the article "*Insecta*," in vol. ii. of the "Cyclopædia of Anatomy and Physiology" (1839), divides insects into: I. *Mandibulata*, containing *coleoptera*, *dermaptera* (ear-wigs), *orthoptera*, *neuroptera*, *trichoptera* (caddis flies),

hymenoptera, and *strepsiptera*; and II. *Haustellata*, containing *lepidoptera*, *diptera*, *homaloptera*, *aphaniptera*, *aptera*, *hemiptera*, and *homoptera*.—Siebold (Burnett's translation), in 1848, gives the following classification: A. Insects without metamorphosis, *ametabola*, containing: 1, *aptera* (*pediculida*, &c.). B. With incomplete metamorphosis, *hemimetabola*, containing: *a*, with suctorial mouth, 2, *hemiptera*; *b*, with mandibulate mouth, 3, *orthoptera*. O. With complete metamorphosis, *holometabola*, containing: *a*, with suctorial mouth, 4, *diptera*; 5, *lepidoptera*; 6, *hymenoptera*; *b*, with mandibulate mouth, with 7, *strepsiptera*; 8, *neuroptera*; and 9, *coleoptera*. This is the same as the classification of Vogt, founded upon embryological principles; and the orders are the same as those of Owen, as given in the 2d edition of his "Lectures on the Comparative Anatomy and Physiology of the Invertebrate Animals" (1855), except that *homoptera* is substituted by him for *hemiptera*. The orders of Milne-Edwards, in his *Cours élémentaire d'histoire naturelle* (1855), are nearly the same as Siebold's, except that *aptera* is omitted, *rhinoptera* substituted for *strepsiptera*, and *anoplura* and *thysanoura* are added. The embryological system of Van Beneden (1855) is the same as the last, the term *strepsiptera* being reintroduced, and *parasita* substituted for *anoplura*.—Prof. Agassiz, in the 2d volume of the "Smithsonian Contributions to Knowledge" (1851), gives the following classification of insects from embryological data:

I. CHEWING INSECTS (<i>Mandibulata</i>).	II. SUCKING INSECTS (<i>Haustellata</i>).
<i>Neuroptera</i> .	<i>Hemiptera</i> .
<i>Coleoptera</i> .	<i>Diptera</i> .
<i>Orthoptera</i> .	<i>Lepidoptera</i> .
<i>Hymenoptera</i> .	

In this the subdivisions are made according to their transformations. From the fact that those undergoing complete metamorphosis have a chewing apparatus in the early stages of their growth, which is gradually transformed into various kinds of suckers, he expresses the belief that the *mandibulata* are lower than the *haustellata*; and he also ranks *lepidoptera* highest among insects, and not *coleoptera*, as generally maintained.—This will suffice for entomological systems; the limits of this article will not permit even the mention of the principal writers in the different departments of the science. Mr. Wilson in the article "Entomology" in the "Encyclopædia Britannica," Dr. Burnett in his translation of Siebold, and Mr. Westwood (*op. cit.*), give valuable lists of the authors on this science, arranged in chronological order; from them we select the following as among the most important since Latreille: in England, Donovan, Curtis, Wood, Rennie, Haliday, A. White, Doubleday, Shuckard, Hope, Newman, and Newport; in France, Jurine, Dufour, Godart, Guérin-Méneville, Boisduval, Dejean, Lacordaire, and Blanchard; in Germany, Meigen, Ochsenheimer, Klug, Fischer de Waldheim, and Germar; in Sweden, Fallen; in America, Thomas Say, Dr. T. W. Harris, and J. L. Leconte. The most use-

ful work on entomology ever published in this country is the "Treatise on some of the Insects of New England which are Injurious to Vegetation," by Dr. T. W. Harris, issued by order of the legislature of Massachusetts; the 2d edition was published in 1852, and a 3d will probably be soon published, with illustrations, at the expense of the state. In this work are adopted the 7 following orders, as generally received by naturalists; a brief sketch of these, with others accepted by many entomologists, will form a proper termination of this article: I. *Coleoptera* (or beetles), with jaws, 2 thick wing covers meeting in a straight line on the top of the back, and 2 filmy, transversely folded wings; metamorphosis complete; larvæ generally with 6 true legs and sometimes with a terminal prop-leg, rarely without legs; pupa with wings and legs distinct and unconfined. II. *Orthoptera* (cockroaches, crickets, &c.), with jaws, 2 opaque upper wings overlapping a little on the back, and 2 larger thin wings folded in fan-like plaits; transformation partial; larvæ and pupæ active, but without wings. III. *Hemiptera* (bugs and plant lice), with a horny beak for suction; 4 wings, of which the upper lie flat, cross each other on the back, and slope at the sides like a roof; transformation partial; larvæ and pupæ like the adults, but wingless. IV. *Neuroptera* (dragon flies, May flies, white ants, &c.), with jaws, 4 netted wings, the hinder the largest; with no sting nor piercer; transformation complete or partial; larva and pupa various. V. *Lepidoptera* (butterflies and moths), with a sucking tube; 4 scaly wings; transformation complete; larvæ with 6 true legs, and from 4 to 10 prop-legs; pupa with the cases of the wings and legs indistinct, and soldered to the breast. VI. *Hymenoptera* (bees, wasps, ants), with jaws; 4 veined wings, the hinder pair generally the smallest; a sting at the end of the abdomen; transformation complete; larvæ like maggots, or slugs, or caterpillars; pupæ with the legs and wings unconfined. VII. *Diptera* (flies, mosquitoes, &c.), with a horny or fleshy proboscis, 2 wings and 2 balancers or poisers behind them; transformation complete; larvæ footless maggots, with the breathing holes generally in the hinder part of the body; pupæ usually incased in the dried skin of the larvæ, but sometimes naked, in which case the wings and legs are visible, and more or less free.—Among the smaller groups, the order *strepsiptera* (Kirby), or *rhypiptera* (Latr.), contains minute insects which undergo their transformations within the bodies of bees and wasps; the maggot-like larvæ live between the rings; the females are wingless, and never leave the bodies of their host; the adult males have 2 very short members instead of fore wings, and 2 very large hind wings; the sharp-pointed jaws are adapted for piercing rather than biting. Their systematic position is not precisely determined; Latreille places them between *lepidoptera* and *diptera*, though he thinks them most nearly allied to some of the *hymenoptera*. The order *aptera*

(Leach), *suctoria* (De Geer), *siphonaptera* (Latr.), *aphaniptera* (Kirby), is constituted by the flea tribe, which seem to be intermediate between *hemiptera* and *diptera*. The ear-wigs, included by most entomologists among *orthoptera*, form the order *dermaptera* (Leach), or *euplexoptera* (Westwood). The spider-flies, ticks, &c., alluded to at the close of the article *Diptera*, form the order *homaloptera* (Leach). The May flies were separated from the *neuroptera*, and elevated to an order *trichoptera* by Kirby. The *thysanoptera* of Haliday consist of the minute insects of the *thrips* tribe, generally classed with the *hemiptera*; other *hemiptera*, as the harvest flies, plant lice, &c., have been separated by the English writers under the name of *homoptera*. Burmeister has separated from *neuroptera* those species which undergo only a partial metamorphosis into the order *dictyoptera*.—Naturalists generally have been disposed to rank insects in the animal scale below mollusca, though many of their vital functions, as of locomotion and perception, indicate a superiority in the former. Mr. Kirby and other English entomologists have accorded the precedence to insects, in opposition to Cuvier and De Lamarck, who placed the mollusca first on account of their system of circulation. In the branch of articulation, the position of insects is well given by Oken, when he says that "*lepidoptera* are born as worms, then pass into the condition of crustacea, and are finally developed into true insects, exemplifying the natural order of gradation of the three classes of articulation." For interesting and conclusive observations on the position that worms are the lowest, crustacea the intermediate, and insecta the highest among articulation, the reader is referred to the paper by Agassiz, above alluded to, in vol. ii. of the "Smithsonian Contributions;" the same authority, in vol. i. of "Contributions to the Natural History of the United States," in the highest class (insecta) of articulation, establishes the 3 orders of myriapods, arachnids, and insects proper, the latter therefore being the highest order of the highest class, and the lepidoptera (butterflies and moths) the highest division in this order.

ENTOPHYTES. See EPIPHYTES.

ENTOZOA (Gr. *entos*, within, and *zōon*, an animal), a group of invertebrate animals, which during some period of their existence live within and derive nourishment from the bodies of other animals, and with few exceptions belong entirely to the class of helminths or worms. Animal parasites form in fact a sort of sub-fauna, and their number is only to be estimated by the extent of the animal kingdom. The classification of entozoa has been attempted by many eminent zoologists since the days of Rudolphi, who may be considered the father of helminthology, but only within a few years has it attained the position of a true science, and chiefly through the labors of a few observers in Germany. Cuvier refers the entozoa to the class *radiata*, and subdivides them, following the plan of Rudolphi,

anioidea or tapeworms, *trematoda* or flat worms, *nematoidea* or round worms, and *acanthocephala* or hooked worms. More correctly, however, they belong to the *articulata*, though the type is a degraded one, and some of them approach in structure the *mollusca*. Adopting this arrangement, we can best explain the past and present state of helminthology by treating these subdivisions separately.—*Tænia*, *cestoidea*, *sterelmintha*, tapeworms. These are parasites in their mature state in the intestines of all classes of vertebrate animals.

In their transitional or immature stage they occur as cysts in the tissues and organs of creatures as form the food of their true hosts or hosts. These cysts, of which the cysts in swine are an example, in the early days of science were not looked upon as of an animal nature, and were called hydatids and locysts; and not until the latter part of the 18th century was their true character recorded. In the 18th, many observers, and especially Götze, noticed that their heads closely resembled those of the tapeworms. His observations were confined chiefly to the *tæniæ* of swine, and appear to have had little influence on the scientific men of the next century, who clung again upon the old and easy theory of spontaneous or equivocal generation, and remained until 1844, when Steenstrup's discovery of alternation of generation was applied to the problem; and Siebold and Dujardin both published essays on the connection between the encysted and encysted forms of various animals. The experiments and those of Küchenmeister must be considered the highest authority on the human helminths, cannot be given in detail here; suffice it to say that tapeworms have been produced in carnivorous animals of all kinds by giving them the encysted variety to eat, and the encysted varieties have been produced in others by administering the eggs or embryos of *tæniæ*. Tapeworms consist of 3 parts, viz.: head, neck, and colony of joints. The head is a minute object, usually square, and provided with varieties of sucking disks and corolla of hooks, by which it attaches itself to the walls of the intestine. The neck is slender and marked by transverse wrinkles, which gradually are converted into joints. With age these increase in number, and finally those first joints become ripe, while new ones are continually given out from the head to supply in turn the place of those discharged. Their growth is usually rapid, and some species attain a length of 20 feet, while others are only a few lines long. Considered as a simple individual, the tapeworm has very limited power of motion, though a distinct layer of muscular fibre is present beneath the skin. This integument is white, moist, and porous; and through this motion is probably carried on by absorption, the only organs subservient to this function being 2 pairs of longitudinal canals running on each side of the joints, and united by transverse branches. The skin contains also

innumerable roundish, concentrically marked, calcareous corpuscles, recognized only by the microscope, which serve undoubtedly as a sort of skeleton. They possess no nervous system. The sexual organs, however, are remarkably developed. When the oldest joints have become sexually mature (which period varies greatly in different species), they pass off spontaneously by the anus—sometimes by the mouth even—of the animal which harbors them. These are flat, quadrangular bodies of a yellowish white color, and in some species are detached singly, in others by groups. These proglottides, as they are called, are true hermaphrodites, contain the sexual organs and eggs or embryos enclosed within shells, and possess the power of moving about; so that they have often been mistaken for trematoda, and, in fact, are now considered as separate individuals. They discharge their eggs either through the genital opening or by self-destruction, which results either from the bursting of their walls or by decomposition. They affect chiefly moist places, and, leaving the manure in which they have been deposited, wander about amid the herbage, and may in this way be devoured; or they fall into water and there, bursting, discharge their eggs, which are thus borne far and wide, and find entrance to a proper soil for future development. They are not capable of a long-continued independent existence, and may even be destroyed within the intestine of their host, scattering their eggs along this canal, though harmlessly; for Leukart found by experiment that eggs when introduced into the intestine before being subjected to the action of the gastric juice remain unchanged; but that when previously submitted to its influence and then placed within the intestinal canal, the embryos became free. Proglottides may even be swallowed entire by animals which wallow in moist manure, and thus introduce a vast number of eggs to their proper dwelling place. When once they have set their offspring free, their object is accomplished and they disappear. Each proglottis contains a vast number of eggs, so that if one out of the many millions reaches a proper habitation the species will continue without decrease in numbers. The embryos are enclosed in firm shells constructed to resist a strong pressure from without, and are either brown or yellowish, and of a round or oval shape. They probably cannot undergo great degree of dryness, heat, or cold, or exist very long in fluid, without the destruction of the animal within. As an example of the usual method of development and transformation of the *cestoidea*, the history of the *tænia solium*, a common tapeworm, will best serve; for it has been most fully studied on account of its frequent occurrence in the form of measles, and its important relation to man. This worm is improperly named, since many are sometimes found in the same intestine. It seldom attains a length of more than 20 feet, and is composed of 600 or 700 joints, which when mature contain myriads of eggs, and escape singly or in

once into the outer world. These eggs being set free find their way into water or manure, and are thus scattered far and wide. By chance one occasionally enters the stomach of man on lettuce, fruit, or unwashed vegetables, but more generally they are swallowed by the hog, the filthy and omnivorous habits of which animal need only be considered to show how readily it may become infected. In either case the egg shell is destroyed by the process of digestion, and the embryo, a minute globular vesicle, armed in front with 3 pairs of sharp spines, emerges and begins its active migrations. It sets out on its travels by boring into the blood or lymph vessels of the stomach or intestine, and is borne along by their currents till it reaches the capillaries, where it renews its activity and bores its way out of the circulatory system into any organ to which chance has carried it. There can

this fact, for Leukart has re-
the embryo several times in
is possible that the embryos
may in some cases lose their hooklets in the vessels, and thus, being unable to proceed further, become encysted in the capillaries. Having reached thus a proper situation for higher development, it becomes surrounded by a new formation or cyst resembling the structure of the organ it may inhabit. If it happens to penetrate any serous cavity, however, this cyst is not formed, but otherwise the development is the same. This process goes on rapidly, so that in a week or two the cyst may be recognized by the naked eye. The spines or hooklets now drop off, the primary vesicle goes on absorbing nutriment, and by the second or fourth week there grows out a protuberance from its internal surface, which soon takes the

tenia. Upon
role of small
the complete
week now be-
gins to extend, but the head still remains enclosed in the bladder, till the whole animal is set free. It may however continue to live in this encysted stage till it dies of old age, unless set free by nature or art; and this undoubtedly is the fate of the largest proportion of these immature creatures. If seated in the muscles, this encysted stage of tapeworm is seldom of injury to man; but if by chance it take up its dwelling-place in the brain or eye, which is not unfrequently the case, results most serious follow. In the hog, however, the case is different, for many eggs being devoured at once, the embryos invade nearly every organ of the body, and produce the disease known as measles. We have still to consider the last and highest stage of development in the life of a tænia, viz.: the conversion of these cysts or measles into the mature intestinal worm. When one of these cysts is accidentally swallowed by man, the little pea-like vesicle bursts, and the head of the worm protruding fastens itself to the intestinal walls by its hooklets. From this head bud out one after another numerous joints, which finally make up

the mature worm. It may be easily understood how these small white cysts gain entrance into the stomach of man, for measly pork is often sold in markets, and although thorough cooking and curing destroy the larvæ, still the cysts may adhere to the knife, and be thus transferred to vegetables, butter, cheese, and the like, which are eaten uncooked. It may often be the case too that pork is so slightly measly, that the butcher does not know the disease is present. There can be no question about the identity of these two forms, the *tænia solium* in man and the *cysticercus cellulosæ* or measles in swine; for not only are their heads anatomically the same, but it had for a long time been noticed that in those places where measles in pork were abundant, there tænia was of most frequent occurrence, and that where the use of this flesh was forbidden among nations or sects, there tapeworm was scarcely ever found. All of this led to the belief, especially after the experiments performed in regard to the tænia and cystic worms of the lower animals, that the measles in flesh were the cause of tapeworm in man. To settle this point Küchenmeister fed a condemned criminal 3 days before his execution on raw measly pork, and on examination after death the young tapeworms were found attached to the walls of the intestine. One point, however, remained to be proved, viz.: that the eggs of the tapeworm produce the measles in swine. For this purpose experiments were undertaken by the Saxon government under the direction of Küchenmeister and other scientific men of Germany. Young and healthy pigs were kept confined separately, and to them were given the eggs of tapeworms. At various intervals afterward they were killed, and the encysted forms were found in myriads throughout the body. These experiments have been often repeated with the same success, so that the result is beyond question. To recapitulate: the tapeworm of the human intestine discharges millions of eggs, a single one of which need only reach maturity to produce millions more; therefore it is evident that the vast majority of these eggs perish undeveloped. These eggs must be devoured by some other host to reach their second or encysted stage. This stage is known as measles in swine. Measles being eaten by man in turn produce the tapeworm. These two forms never produce each other in the same individual. Various other tæniæ infest man in one of their stages, the most dangerous of which is the *echinococcus*, or encysted form of *E. hominis*. The cysts produced by this parasite are often as large as a man's head, causing great suffering and death. In Iceland every seventh person is thus afflicted. The explanation of this lies in the filthy habits of this people, and in the great number of dogs they keep, which assist in spreading the seeds of the disorder. Here the cysts or hydatids contain instead of one scolæx or head innumerable embryonic forms, which of course increases the risk of infection. The mature tapeworm produced artificially

consists of but 3 joints, and on this account has hitherto escaped notice. Even now it is not known whether man himself or dogs are the hosts of the mature helminth. Another remarkable species dwelling in the intestinal canal of man is the *bothriocephalus latus*, or broad tapeworm. This differs from the true *tæniæ* in the construction of its head and joints. The former is oval, flat, and instead of a coronet of hooks and round suckers, possesses 2 longitudinal sucking grooves on each lateral margin, by which it fixes itself; the latter are one-third of their width only in length, and the genital opening is found on the middle of each joint, instead of at the lateral margin, as in *tæniæ* proper, and occurs on the same surface throughout its whole length. They are sometimes as many as 2,000, but even then they do not make up a worm more than 20 feet long. Thus far this parasite has been found in man only in its mature state. Its geographical distribution is limited to Russia (including Poland), Switzerland, Italy, and the maritime districts of France and north Europe, and it most probably undergoes its transitional stage of development outside the human intestine in some of the mollusks, which form the food of man. A few other species of tapeworm infest mankind, but they are seldom met with, and will be found enumerated in the accompanying catalogue. The dog, from his domestic and omnivorous habits, is made the host of many of these entozoa, and does much to keep up their precarious existence. Without his aid the *tania caninus* would undoubtedly become extinct, and thus the sheep breeders would be rid of a disease which often proves so fatal to their flocks, viz., the staggers. This disease is caused by the presence in the brain of hydatids or cystic *canini*, which when eaten by butcher and sheep dogs are converted into the corresponding *tania*, the embryos of which are in turn scattered broadcast over the pastures, where they find ready admission to the grazing herds. This too has been made the subject of searching investigation in Germany, and shepherds are taught to keep their dogs free from this tapeworm, by putting out of their reach the flesh of animals afflicted with the staggers. Sheep may often be kept healthy by keeping them from moist places, and from pastures, while the dew is still on the grass, for the proglottides seem to seek such localities, and the heat of the sun appears destructive to their vitality. Much more good may be effected by such preventive measures than by administering anthelmintics, or by attempting the removal of the cysts by the trephine or trochar. Did the raiser of swine, too, but know the natural history of the measles which infest his charge, this loathsome disease would be seldom met with. Very often immense droves of these creatures have to be slaughtered on its account, and such attacks always prove that the victims have lately been in the neighborhood of some person who has a *tania solium*. Wild swine are never affected in this way, and it is only the filthy na-

ture of its food which produces it in the domesticated animal. Occasionally this variety of *cysticercus* is found in the flesh of other animals eaten by man, as the ox, deer, and bear; but very seldom. No doubt a great deal of measly pork is sold both fresh and salted, and enough is eaten in an uncooked state in the form of sausages, raw pork, and the like, to account for the wide distribution of *tæniæ*. Dr. Weinland, in his recent essay on human *cestoidea* (Cambridge, 1858), divides the *tænioidea* into two classes: First, the *sclerolepidote* or hard-shelled tapeworms, the embryos of which, developed in the warm-blooded vertebrata, become mature *tæniæ* only in the intestinal canal of carnivorous mammalia. Thus man obtains the *tania solium* from swine; the dog the *T. serrata*, *T. caninus*, and *T. echinococcus* from the rabbit, the sheep, and the ox respectively; the cat the *T. crassicolis* from the mouse, and so on. Second, the *malacolepidote*, or soft-shelled tapeworms, the eggs of which are to be hatched in the stomach of articulata and mollusks. The mature entozoa of this order inhabit the intestinal canal of such animals as prey upon the above, as fish, birds, and insectivorous mammalia.—*Trematoda, stercoraria* (Owen), isolated flat worms. These entozoa are characterized by their flattened, more or less elongated shape, and by ventral sucking disks. The same individual possesses the organs of both sexes. Rudolphi divided them into different genera, according to the number of cup-like suckers present. This classification has been given up, inasmuch as the more important distinctions of structure did not correspond to the external markings; but many of the names have been retained. Thus the *distoma hepaticum*, or liver fluke, has 2 sucking disks. This, the best known of the trematode worms, resembles much a cucumber seed in form, and measures in length one inch, in width about half an inch. Its color is of a yellowish brown, probably owing to the bile in which it lives. In this class we first find evidence of an alimentary canal, in addition to the sexual organs, thus giving it a higher rank than the *cestoidea*. This consists of a triangular opening or mouth, which may be used either as a sucker or means of obtaining nutriment. From this arises the intestinal canal. An excretory system is also present. This fluke has been found only in a few well-authenticated cases in man. Its true home is in the gall ducts of sheep, and it is generally found in the same place in the human system. There are cases, however, on record in which it has been found seated beneath the skin, having made its way thither by boring into the epidermis. In the liver of the lower animals it works sad havoc in autumn and winter, causing a dilatation and catarrh of the gall ducts, and an interference with the hepatic function; by which, of course, the secretion of the bile is disturbed and changed. They may occur in such quantities as to stop up the cystic duct, and their eggs are deposited in vast numbers in the bile. The symptoms they create in man need not be stated here. The pas-

sage of this worm by the stomach or intestines is the only proof we could have of its presence before death. The generation and development of these worms has been a subject of great interest to naturalists, since Steenstrup made them the object of investigation in illustrating his theory of alternation of generation. The eggs of the *distoma*, escaping from ciliated embryos, become converted into a nurse or grand-nurse while in the water. These nurses or *cercariae* are supplied with organs of self-support, and were formerly looked upon as mature animals, but are merely cradles for young *distomata*, which are produced within their canal, or, where this is wanting, within the simple sac, from the germinal granules retained from the original embryo. This young brood possesses in some species tails by which they undertake wanderings on their own account, become attached to mollusks or like animals, and thus find their way into the intestine and liver of some larger animal. Another way exists by which they may reach the intestine; for the tailless brood have the power of encysting themselves while in the water, and may thus be borne about till they are swallowed by some of the herbivora. This is the general plan of development in all trematode worms, but it is not yet known what peculiar metamorphoses this entozoon undergoes. There can be little doubt, however, that sheep infect themselves by devouring snails which frequent the grass in moist meadow pastures, or by drinking ditch water. Whether "the rot" is actually caused by this parasite is not certain, but they are always found in this disease. Little benefit is to be derived from the use of anthelmintics, but a proper attention to these laws of prophylaxis will aid the farmer much in preserving his flocks in a healthy condition. The *distoma hematobium* forms a very common disease in man in Africa, according to Billarz, who found it first in the blood of the portal and mesenteric veins. Their chief habitation, however, is the bladder and intestines, and when present in numbers they are very detrimental. In the bladder they fasten themselves to the mucous membrane, and produce patches of inflammation, exudation, and hemorrhage. The fungous excrescences they cause are pedunculated, and often of the size of a pea. Within them the animals may be found, and on their external surface the eggs. In the ureters the inflammation they create is sufficient to produce stricture, and consequent atrophy of the kidney. Several other species of trematode entozoa have been found both in man and herbivorous animals, but they can only be enumerated in this article. Some of them infest the eyes of animals, and are sometimes found in such prodigious quantities as to almost fill the cavity of the eyeball.—*Acanthocephala*, *sterelminta*, hooked worms. This group of entozoa, which resembles the *nematoidea* in form and distinction of sex, approaches more nearly the *trematoda* in its digestive system. It includes some of the

most noxious of the parasitic helminths, but none infest man. They are included under one genus, *echinorhynchus*, which is characterized by its retractile proboscis, armed with recurved spines. It is found in the intestines of the hog and other animals.—*Nematoida*, *culelmintha* (Owen), or round worms. This class is made up of the round worms which inhabit the intestine, lungs, and kidneys of man and the lower animals, or else are enclosed within cysts in the muscular system or beneath the epidermis. They too undertake migrations and undergo transformations, but we are less acquainted with their development than with that of the first two classes; all that we know of them is, that we find sexually mature and embryonic forms, but to trace a connection between them, or to discover their mode of growth, has hitherto been impossible. They are distinguished from the *cestoidea* and *trematoda* by a more elaborate digestive apparatus, by a nervous system, and by individuality of sex. Most of the species are oviparous, and the development of their eggs has been lately made the study of helminthologists. The ova are enclosed in hard shells, within which under suitable conditions the embryo is further developed by segmentation, till it breaks from its habitation, and comes forth either a perfect worm, or in an intermediate form, in which it wanders into the tissues of man and other animals, where it may undergo the encysted stage, and finally on escaping become the mature individual, when it has found again a suitable habitation. The largest of this class is the *strongylus gigas*, which belongs to the dog and other animals, but which has been found at rare intervals in the human kidney. It is a long, cylindrical, red monster, with a mouth made up of 6 papillae. The male, as usual in the *nematoida*, is the smaller, measuring from 10 to 12 inches, while the female sometimes attains the length of 3 feet, and is half an inch in thickness. This sea serpent of the human entozoa seems really to cause very little trouble. Like the *ascaris*, its relative, its fine red color seems owing to a reddish oil secreted by the vacuoles of the skin. Another species, *S. equinus*, is very common in the intestine of the horse, and *S. longiraginus* has been found in the lungs and bronchial glands of man. The *ascarides* are very numerous, and inhabit the intestines of many animals. The *ascaris lumbricoides* is the largest which infests the human intestine. It is found all over the world, and prefers the lower part of the small intestine. It is of a pale, pinkish hue, cylindrical and elastic, has pointed extremities, and varies greatly in size according to age and sex. The male measures from 4 to 6, the female from 8 to 18 inches in length. The head is trilobulate with a constriction below the papillae, which serve as sucking surfaces. The intestinal canal is a straight tube piercing the centre of the worm from end to end. They are very prolific, and as many as 64,000,000 ova have been found in one female. These eggs when immature are triangular and

very irregular in shape, but when impregnated are enclosed in oval shells, within which the process of segmentation is carried on. Whether it is their nature first to go through a developmental stage outside of man, and to gain readmission in food or in drink, is not known. The great numbers in which they are sometimes found, even as many as 300 or 400, leads to the belief that they may under favorable circumstances reproduce themselves in the original host; and the wanderings which individuals make upward may be the promptings of a blind instinct to deposit their eggs in the stomach, where their shells may undergo the solvent action of the digestive process. Wherever an opening exists between the intestine and any cavity or organ of the body, it may prove a loophole for the passage of this active parasite, and in this way its presence in strange places, as the bladder or abdominal cavity, may be accounted for. At all events, it is impossible for it to make an opening through the intestine or any tissue of the body, for it is without the means of doing so. The presence of ascarides has been attributed to illness and bad flour and bread. They are most abundant in moist localities, as sea-coasts and river valleys, and they may gain admission to the intestines on raw fruit, or in mollusca and larvæ of insects, which abound in such places. Bad food or the want of food will undoubtedly cause their discharge, as well as illness, but only because they are starved out, and because bad food and sickness generate an unhealthy action in the intestine, which thus becomes disagreeable to them. So their discharge is more frequent in summer, but it is on account of the frequent diarrhœas which follow the eating of green fruits and vegetables, by which they become sickly and are expelled, and not because they are generated by such food of itself; for it must take a long time for them to reach maturity, and they are seldom seen before this age. All attempts to produce these worms in the lower animals by administering eggs have thus far failed.—The muscles of man are sometimes found after death to present a sanded appearance, which is caused by the presence of innumerable little cysts scattered throughout their substance, generally isolated but in immediate contiguity. These minute bodies when examined microscopically are found to contain immature worms coiled up in the narrowest compass. When set free they unfold themselves, and move about in a lively manner. They are cylindrical and tapering, and their name is *trichina spiralis*. They are also found in the muscular system of the hog. Now in the small intestine of man all the world over is often found a small thread-like worm coiled up or extended, which is the *trichocephalus dispar*. They sometimes occur by hundreds, and were formerly but erroneously supposed to be connected with the diarrhœa of typhoid fever. Recently helminthologists have thought they recognized sufficient resemblance between them and the encysted *trichina* above mentioned, to consider the one the un-

developed or embryonic stage of the other. This opinion is based on anatomical grounds, which need not be repeated here. The interesting discovery by Leidy of trichinous pork teaches us how, as we have shown in measles, man may infect himself with the *trichocephalus*. How he gets the *trichina* is not so easy to explain, as it is not known whether the embryo on emerging from the egg has the power of burrowing into the blood vessels. If the worm by wandering upward deposits its eggs in the stomach, we can readily see how the embryos, if they do possess this power, may spread themselves throughout the body.—One more of the human entozoa is sufficiently interesting to be mentioned here at length, viz.: the *filaria medinensis*, or Guinea thread worm. This is confined to certain localities in the tropical regions. It is seldom over 3 yards long, and is found of all lesser sizes according to its age. The male has not yet been described, for either its small size prevents detection, or else it never occurs in man. In shape the female resembles a flattened cord, one line in diameter. Its color is pale yellow, and it is viviparous. Its head is circular and armed with 4 straight, pointed spines, by which it probably penetrates the tissues. It inhabits the subcutaneous areolar tissue, and chiefly that of the ankles, feet, and legs; but it has also been found in the abdominal parietes and arms. It often proves an endemic, attacking certain regiments in armies and sparing others. It appears to follow the rainy seasons, and to occur mostly in low and marshy districts. There can be hardly any doubt that this animal is an inhabitant of wet places, and that man infects himself only by allowing it to come in contact with his skin. Those who take great precaution against wetting their feet, sleeping on the ground, and bathing in marshy pools, generally escape it. The worm may lie coiled up or extended at full length beneath the skin. As many as 50 individuals have been observed in one person, but usually one alone occurs. If superficial, its growth may be watched from day to day, and it has been seen to increase more than an inch in 24 hours. It often lies concealed for a long time, however, without causing any symptoms of its presence, and may thus be borne from one country to another by its host. When about to open externally, a little boil is found at some point on the skin, which either bursts or is opened, and the anterior end of the worm protrudes. It is removed by seizing this and making gentle traction. All that readily yields is wound about a compress, and bound down over the wound till the following day, when the same process is repeated till it is wholly extracted. Great care is taken not to break the worm, for serious results often follow such accidents. It is probable that the young or germs inhabit wet soils, and enter the tissues of other animals to attain their full development after being impregnated outside. The attempt of the mature female finally to escape would seem to imply

that, its end being accomplished, it would return to its former home, and deposit its young, where new hosts may offer themselves for their reception.—We append a list of well authenticated helminths found in some stage in man. 1. CESTOIDEA: *tænia solium*; *T. e cysticercus tenuicollis*; *T. mediocanellata*; *T. nana*; *T. e echinococco altricipariente*; *T. e echinococco scolicipariente*; *bothriocephalus latus*. 2. TREMATODA: *monostoma lentis*; *distoma hepaticum*; *D. lanceolatum*; *D. heterophyes*; *D. hæmatobium*; *D. ophthalmobium*. 3. TREMATOIDEA: *tricocephalus dispar*; *oxyuris vermicularis*; *ascaris lumbricoides*; *strongylus gigas*; *S. longivaginus*; *ancylostomum duodenale*; *filaria lentis*; *F. medinensis*. Many other varieties of these 3 classes have been observed, but not enough is known of them as yet to raise them above the list of the strayed or the accidental, or to give them a place among the proper parasites of man.—The administration of drugs in the encysted stages of tapeworm would of course be useless, and their diagnosis is often a most difficult problem to the physician. The following remarks apply then only to the intestinal forms. Nothing should be done until the passage of joints gives the infallible sign of the presence of the worm. All statements of patients regarding their own symptoms must be received with much doubt. A long catalogue of fearful and frightful ills is ascribed to their presence, but probably in the majority of cases without any cause whatever. It is true that the worm feeds upon the nutriment of the patient, but this has not yet formed a part of his organization, and is not oxygenized. Whether epilepsy is ever caused by tapeworm is a matter of great doubt, and more valid proof is needed to show more than a coincidence between the presence of the two. Whenever a person harboring one of these becomes ill in any way, from any cause inexplicable, the parasite receives the entire blame. Some species cling more firmly than others, and are more difficult to dislodge. Of course, unless we obtain the head we fail, for the *scolex* may go on producing new colonies indefinitely. The only way to effect their removal is to render their habitation disagreeable to them. A long list of anthelmintics swells the works on materia medica, but the following are the only trustworthy remedies: the roots of the male fern, pomegranate bark, oil of turpentine, kousso, and pumpkin seeds, all of which should be employed in connection with a subsequent course of cathartic medicine. No remedies as yet discovered are of any avail in the treatment of the *trematoda*, and their presence can only be correctly diagnosed when their passage into the outer world is observed. Among the *nematodea*, the *oxyurides*, or pin worms, are the most troublesome, on account of the intolerable itching caused by their nightly wanderings outside the intestine. No treatment can wholly remove them, but cathartics and cold enemata are the best remedies. The administration of santonine or some of its compounds will be

found to act as a true vermifuge in the treatment of ascarides.—The bibliography of helminthology has received many valuable additions within the last few years, since it has become a distinct science. For a more complete account of its progress than the nature of this article allows, the following books may be referred to: Rudolphi, *Entozoorum sive Vermium Intestinalium Historia Naturalis* (3 vols. 8vo., Amsterdam, 1808); Steenstrup, publications of Ray society, "Alternation of Generation" (8vo., London, 1845); Bremser, *Ueber lebende Würmer im lebenden Menschen* (4to., Vienna, 1819); Diesing, *Systema Helminthum* (2 vols. 8vo., Vienna, 1850); Dujardin, *Histoire naturelle des helminthes ou vers intestinaux* (8vo., Paris, 1844); Van Beneden, *Vers cestoides ou acotyles* (4to., Brussels, 1850); Leuckart, *Blasenbandwürmer und ihre Entwicklung* (4to., Giessen, 1856); Owen, "Lectures on Invertebrata" (8vo., London, 1843); Küchenmeister and Von Siebold, translated in Sydenham society publications (2 vols. 8vo., London, 1857); Leidy, "A Flora and Fauna within Living Animals," Smithsonian publications, vol. v. (4to., Washington, 1853); Weinland, "Human Cestoides" (8vo., Cambridge, 1858).

ENTRECASTEAUX, JOSEPH ANTOINE BRUNO', a French navigator, born in Aix in 1739, died at sea near the island of Waigeo, in the Pacific ocean, N. of New Guinea, July 20, 1793. He entered the naval service in 1754, gradually rose to the position of commandant of the French fleet in the East Indies (1786), and in 1787 he became governor of Mauritius and the Isle of Bourbon. In 1791 he was sent by the French government in search of La Pérouse, who had not been heard from since Feb. 1787. He failed in detecting any trace of him, but ascertained with great exactness the outlines of the E. coast of New Caledonia, W. and S. W. coast of New Holland, Tasmania, and various other coasts.

ENTRE DOURO E MINHO. See MINHO.

ENTRE RIOS, a state of the Argentine confederation, South America, deriving its name from its situation, between the rivers Uruguay and Parana, bounded N. by Corrientes, E. by Uruguay, S. by Buenos Ayres, and W. by Santa Fé and El Gran Chaco; area estimated at 32,000 sq. m., occupied by alternate tracts of prairie and swamp land, and mostly uncultivated; pop. in 1855, about 50,000. In the southern part is an extensive alluvial plain, subject to annual inundations. The climate is mild and healthy. Sudden changes of temperature never occur, and frost is almost unknown. Vast herds of horses and cattle roam over the prairies, and the exportation of hides, horns, tallow, and jerked beef is the chief source of the wealth of the state. Parana, Ybicuy, and Concepcion de la China are the principal towns.

ENVELOPE, a paper covering for a letter, introduced into general use in Great Britain soon after the passage of the act of parliament of Aug. 17, 1839, which provided for the payment of postage by weight instead of by the number

pieces of paper. In 1841 it was found that half the correspondence passing through the post office of the United Kingdom was in envelopes; and in 1850 100 out of every 112 were thus protected. In the United States their adoption followed more slowly the change in postage introduced by the act of 1845; but for several years past they have been almost universally employed. For some time envelopes continued to be cut out and folded by hand, but the increasing demand led to the invention of exceedingly ingenious machines for furnishing them with extraordinary rapidity. Formerly they were cut into form by chisels, the paper, roughly shaped, being held in a templet or mould of the proper pattern. The folding was then completed by hand with the use of a bone folder. About 3,000 were as fast as an expert person could thus prepare in a day. In 1845 Messrs. Edwin Hill and Warre la Rue obtained in England a patent for an envelope machine, covering also the apparatus for cutting out the blanks. By this machine from 45 to 60 envelopes per minute are produced, all precisely alike, making in a day of 10 hours, with proper allowance for stoppage, from 500 to 30,000, of which not more than one in 100 is found to be badly folded. The blanks are cut into a lozenge shape by an instrument in the center like a punch for cutting gun wads. The machine cuts out 250 blanks at once, and passes for making the diagonal cuts in a diagonal direction across the paper, so as to reduce the waste to the least possible amount. The seal upon the flap is next effected at the embossing press, and the gum is applied by hand to this flap. A boy then places one by one upon a small table forming the supporting frame attached to the machine, the inner flap of which is of the size and shape of the envelope when finished. A plunger fitted to be brought down by a revolving cam and presses the paper into the mould, causing the flaps to stand up at right angles to the central line of the paper. The plunger is so made to rise and fall, and these are so connected with the movements of the cam, that the portions covering the two ends of the envelope first rise up, and at the same time two triangular folders, one at each end, turn over and press down the end flaps, one of them a little in advance of the other. Another portion of the apparatus now applies a line of gum on the two end flaps, as they are thus held down. The side portions of the plunger then rise up, and the side folders turn the long flaps over, one a little ahead of the other. All 4 folders then open; a finger-like apparatus advances from the side, the tips of the fingers tipped with caoutchouc, lift the envelope up with the frame supporting them, then withdrawn to one side, and applied to a revolving belt, by which it is carried under a roller, and finally deposited in a pile on one side of the machine. The apparatus is so arranged as to admit of its being adapted for envelopes of different sizes. It is worked at the rate of about one every second, and in

case of omission to furnish an envelope at every revolution of the main cam, the attendant must instantly move a stop which lifts up the gummer and prevents the application of gum to the table where the envelope should be, as also the movement of the fingers, which would otherwise derange the envelope last deposited.—Another remarkable machine for this simple work of folding and gumming the small pieces of paper for envelopes, constructed by M. Remond, of Birmingham, was shown at the great exhibition of 1851. To this the blanks are supplied by means of a hollow arm, which as it moves forward is exhausted of air, and in this condition coming over the pile of prepared blanks, one of them at the top is caused by the atmospheric pressure to adhere to the double tubular end, and is thus carried along till the tube becoming filled with air drops the blank upon a spot where by the descent of a dabber it is pressed against a sponge saturated with gum from the receptacles with which it is connected. The gum being thus laid exactly where it is required, and the stamping or embossing being at the same time effected, the paper is next pressed into the hollow mould, and its flaps stand up as in the other machine; the plunger retreats, and a puff of air blown successively through each of the 4 sides, which are perforated to admit it, turns these down, and the re-descent of the plunger secures them in their places. They are finally taken out by hand, placed in a pile, and slightly pressed.—In the United States, hand-made envelopes were first furnished to the trade by Messrs. Bell and Gould and Mr. George F. Nesbitt of New York. The former house afterward obtained a machine, contrived by Mr. Gerard Sickles, which is understood to have done good service, though since surpassed by others of later invention. Mr. Nesbitt was not long in securing another, which in general plan resembled that of De la Rue, though much more simple and perfect. In his establishment he employs about 8 machines, the capacity of each of which is about 30,000 envelopes per day. The machines occupy but little room, 5 of them standing as they are worked in a space of about 18 feet in length and less than 4 feet in breadth. Each one is in an iron frame, about 5 feet high, 2 feet from side to side, and 16 inches from front to back. The feeding shelf projects in front about 2 feet more. The power is applied to a driving pulley upon one end of a horizontal axis or shaft along the top of the frame. The pulley is put in gear by placing the foot upon a treadle at the base, and is thrown out on removing the foot. In the middle of the axis is a crank giving 9 inches stroke and carrying the vertically moving plunger. Near the pulley is a cam on the shaft for the movements connected with the gumming, and at the other end of the axis is the crank for working the various other movements of the machine. The machines are worked by females, one to each. As the foot is placed upon the treadle, a blank cut by the usual method is laid carelessly upon the feeding shelf. It is imme-

diately taken along and worked into its exact place, and a second is started before the first has reached the centre under the plunger. While this is coming down, a pair of gummers, at an obtuse angle to each other, having received their supplies of gum from the receptacle with which they are connected, are brought over the wide back flap and dab a little gum upon the edges of this. The plunger immediately follows, and carries the blank down through the opening, which it exactly fits, leaving the flaps standing up. The plunger rises, and the two end flaps are pushed over in turn, and upon them the back flap, fastening all three together. The last shutter closes over the front flap, the bottom of the mould falls back upon its hinges, and the envelope falls through into a tin slide, down which it slips into an upright tin box placed to receive them. This box makes a quarter revolution on its axis with every 25 envelopes, and these are consequently arranged in the box in piles of 25, crossing each other, ready for counting and boxing. The new style of envelope lately introduced by Mr. Nesbitt, having black lines on the inner side of the back flap, to serve as a guide in writing the address before the letter is put in, is intended to be prepared in the machine by the introduction of some additional parts. Most of the commercial "lined envelopes" are prepared by Mr. Nesbitt. They are mostly very large-sized envelopes of paper with a bluish tinge, secured before cutting to a backing of cotton, or as it is called, muslin. The whole is then made up, usually by hand. These envelopes are used for protecting money and valuable papers transmitted in commercial transactions. Messrs. McSpedon and Baker are also large manufacturers, producing probably 25,000,000 envelopes annually; and J. Q. Preble probably a still larger number, using machines of several kinds. Messrs. Hartshorn and Trumbull, of Worcester, Mass., employ about 17 machines, the invention of Dr. R. L. Howes, of Worcester, the capacity of each of which is about 10,000 a day. They employ steam power, and produce about 45,000,000 envelopes annually. In these machines the envelopes placed in a pile are brought up from beneath the table by a counterpoise, and the top one is immediately taken up by the gummer, which comes down upon it, and leaves the required quantity of gum in the right place to secure the end and back flap—the front one, as in all machines, being first gummed by hand and dried. The paper dropped by the gummer is then taken by a carriage under a double plunger, the outer portion of which forces it down into the mould, and an inner part follows, turning over the flaps in succession. After the plunger rises the bottom of the mould is pressed up by a spring, and the envelope brought again to the surface is taken by the same carriage back, and delivered upon a slide which drops it into a receiver.

ENVERMEU, a small town of France, in the department of Seine-Inférieure, Normandy; pop. about 1,500. It is situated within a few

miles of Dieppe, and contains the site of an ancient Frankish cemetery, explored from 1849 to 1856, by the abbé Jean Benoît Désiré Cochet. His researches have proved very valuable to archæological science. The greater part of the graves had been violated at some remote epoch, but a few of them remain intact. One of the most remarkable of these is the grave of a young person, with ear rings of bronze, with oval pendants of gold. Close to the ear rings were 25 to 30 threads of gold, which (the greater part still remaining interlaced) appeared to have belonged to a woven band, or fillet, which time had entirely destroyed. Similar relics were found at Kertch in 1838, and such interments with ornaments were common among the ancient Greeks and Etruscans. One of the graves in the Saxon cemetery at Chessell, in the isle of Wight, opened in 1855 by Mr. George Hillier, contained similar filaments of gold. Among the relics discovered at Envermeu are swords, sabres, bronze buckles, a Gaulish coin or rather ingot of gold, which presented on the reverse an ill-formed miniature horse (supposed to belong to the era of 270 to 100 B. C.), bronze ear rings, necklaces composed of glass beads, iron axes (*francisca*), accompanied by iron lances (*framæ*), iron spurs, arrow points, iron daggers ornamented at the point with a plate of bronze and flanked by small knives, elegant bronze purse clasps, &c. The cemetery seems to have been of a circular form, and was probably once covered by a tumulus, long since removed by the operations of agriculture. The abbé Cochet (born near Havre, March 7, 1812) is one of the most active French archæologists of the present day. Among his latest works on his researches in Normandy are: *La Normandie souterraine, ou notices sur des cimetières Romains et Franks explorés en Normandie* (Rouen, 1854, with plates), and *Sépultures Gauloises, Romaines, Franques, et Normandes* (Dieppe, 1857).

ENZINA, or ENOINA, JUAN DE LA, founder of the secular theatre in Spain, born in 1468 or 1469, died in Salamanca in 1534. He was educated at the university of Salamanca, spent some time in the household of the first duke of Alba, afterward went to Rome, where he became a priest, and, from his skill in music, chapel master of Leo X. In 1519 he made a pilgrimage to the Holy Land. At least 6 editions of his collected works, divided into 4 parts, were published from 1496 to 1516, containing lyrical poetry, songs, and several descriptive poems. But his most important works are his dramatic compositions, which he called *Representaciones*. They are in the nature of eclogues, interspersed with songs, but deficient in dramatic structure. They were first represented before the duke of Alba, and in 1492 companies began to represent them publicly.

ENZIO, a natural son of Frederic II., emperor of Germany, born in 1224 or 1225, died in Bologna, March 14 or 15, 1272. He was handsome, accomplished, and chivalric, and took a distinguished part in the contests of his father with

Guelphs. As early as 1237 he accompanied to the battle of Corte Nuova. About 2 years afterward he married Adelasia, marchioness of Massa, the widow of Waldo Visconti, and heiress of important possessions in Italy. On this occasion he was created king of Sicily; but it was only a nominal dignity. A more substantial one conferred on him by the emperor was that of governor-general of Lombardy and of commander of the German troops against the Milanese. Gregory IX. excommunicated Frederic, Nov. 11, 1239; the pope's rancor increased the ardor of Enzo, and he conferred on his father many towns in Umbria. Commander of the emperor's naval force in Sicily, he defeated, in conjunction with the Pisan and the Genoese in the vicinity of Leghorn, the island of Meloria (May 8), after a protracted engagement. A great number of prelates were on board of the Genoese galleys, about to attend, in spite of the emperor's remonstrance, a council convoked at Rome by Gregory IX.

All these prelates, about 100 archbishops, bishops and 3 legates of the pope, were captured; the total number of prisoners was estimated at 4,000. The booty taken from the Genoese comprised a large amount of money, and in consequence of this success, the prelates were removed to prison in chains made of silver. After this and other victories over the Guelphs, the Ghibellines were defeated, May 26, 1249, in the bloody battle on the Fossalta. Enzo being made prisoner, the Bolognese condemned him to perpetual imprisonment, and refused to release him, although the emperor was ready to pay any amount of ransom for his son. He continued in prison for 24 years, surviving all the sons and grandsons of Frederic, who all met with a violent end. Stories were circulated about the attempts of his friends to effect his escape by conveying him in a barrel of wine which was supplied for his table; it was also said that he had been imprisoned in an iron cage, but although closely guarded, he seems to have been treated with kindness.

Eocene (Gr. *εως*, dawn, and *καινος*, recent), the lowest group of the tertiary formation, so named by Sir Charles Lyell in making the divisions of this series, from the fact that among the fossil shells with which the strata abound, we are met with of species identical with those now living; and as all those in the next formation (the secondary) are extinct, the tertiary strata may be regarded as indicating the dawn of the existing state of the testaceous fauna. The division being based on the proportion of recent species of shells to those which are extinct, which proportion in the original arrangement was determined from an examination of 1,288 species to be about 3½ per cent., the upper boundary line of the group cannot be determinately fixed. New sets of fossils are occasionally met with, which may be referred either to the eocene or to the miocene which succeeds it, a group which is characterized by containing a much larger number of ex-

isting species. The formation is largely represented in the London and Paris basins, the numerous fossils of which afforded the means of establishing this classification, and of subdividing the group into 3 divisions called the upper, middle, and lower eocene. It is recognized near the southern coast of the United States, extending from Delaware south, the more recent members of the tertiary formation commonly intervening between it and the coast line. The locality best known and studied is at Claiborne, Ala., where no less than 400 species of marine shells, with many echinoderms and teeth of fish, are found in one member of the group. It is also met with in Nebraska, and in other parts of the valley of the Mississippi. The strata included in this division are sands, clays, marls, gypsum, sandstones, limestones, brown coal; indeed, all the varieties of sedimentary rocks, &c.

ÉON DE BEAUMONT, CHARLES GENEVIÈVE LOUIS AUGUSTE ANDRÉ TIMOTHÉE D', commonly called the chevalier d'Éon, a French diplomatist, who owes his notoriety to doubts which long existed as to his sex, born in Tonnerre, Burgundy, Oct. 5, 1728, died in London, May 21, 1810. He was of good family, was well educated, became a doctor of canon and civil law, and an advocate before the parliament of Paris, and at the outset of his career applied himself with some success to literature. In 1755 Louis XV. employed him in a delicate diplomatic mission to Russia in company with the chevalier Douglas. Favored by a beardless face, he assumed the dress of a woman, and blending a woman's tact with a politician's cunning, gained the good graces of the empress Elizabeth, became her reader, and having bent her mind to the wishes of the French court, went back to Paris to announce his success. He immediately revisited St. Petersburg in male attire, passed himself upon Elizabeth as the brother of her former favorite, was again successful in his negotiations, and on his way back to France appeared as envoy at Vienna. Having previously held a commission in the army, he was promoted to a captaincy of dragoons in 1758, served with the forces on the Rhine, and acted as aide-de-camp to Marshal de Broglie during the campaign of 1762. He was then secretary of embassy, and afterward minister plenipotentiary, at London; but being superseded in 1763 by the count de Guerchy, and mortified moreover by being named secretary to his successor, he revenged himself by publishing a complete account of all the negotiations in which he had been engaged, exposed many secrets of the French court, and reflected with equal severity upon friends and enemies. Among the victims of his slander was De Guerchy, who consequently brought an action in the court of king's bench, in which D'Éon was convicted of libel in July, 1764, and was finally outlawed. Meanwhile he caused De Guerchy to be arrested on a charge of an attempt to poison him, but the affair ended in nothing. He continued to reside in England, subsisting for a time

by borrowing and various expedients, and afterward on a pension which Louis XV., notwithstanding his misconduct, allowed him for his secret services both in England and Russia, and, after the return of the count de Guerchy to France, acting as the representative of the court of Versailles, though not officially recognized as such. About 1763 rumors respecting his sex, which received color from his adventure at St. Petersburg, his appearance, his manners, and still more from the reports spread by his enemy De Guerchy, became common topics of conversation in the British capital; bets to a large amount were laid that he was a woman, and a wager of this sort became matter for a lawsuit before Lord Mansfield, in which the plaintiff, having brought witnesses to swear that D'Eon was a female, obtained a verdict for £700. In 1777 he went to Versailles, where Louis XVI., for reasons which have never been made known, forced him to exchange his dragoon's uniform for a woman's dress. He returned to England in this garb to collect his effects, and while there was placed on the list of *émigrés* by the revolutionary tribunal established during his absence. He supported himself in London by the sale of his library, by giving exhibitions of his skill in fencing with the famous Mons. St. George and Mr. Angelo, and by a pension from George III. He made one more visit to his native country, and under the name of Madame d'Eon petitioned the national assembly for leave to serve in the army; but obtaining nothing but applause by his request, he passed the rest of his days in poverty in England, retaining till his death, either through habit or for convenience, the garb which had been forced upon him 33 years before. A post mortem examination left no doubt of his being a man. He wrote a number of historical, political, and other works, filling 13 vols. 8vo.

EOS. See AURORA.

EÖTVÖS, JÓZSEF, baron, a Hungarian author and statesman, born in Buda, Sept. 3, 1813. His education was completed at the university of Pesth, and at the age of 17 he commenced his literary career by a translation of Goethe's *Götz von Berlichingen*. This was followed by two original comedies and a tragedy. In 1836 he travelled through Germany, Switzerland, France, and Great Britain. In 1838 he became the editor of the *Budapesti Arvitzkönyv*, a work in which the most eminent Hungarian men of letters took a part. He contributed to it a novel entitled the "Carthusian," which made him at once the favorite of the Hungarian public. A pamphlet issued by him on prison reform produced a deep impression. His eloquent defence of the "Emancipation of the Jews" was still more remarkable. In the great controversy about Kossuth's *Pesti Hirlap*, Eötvös espoused his cause, and published a pamphlet in 1841 defending him against the conservative leader Széchenyi. As one of the leaders of the opposition in the upper house of the Hungarian diet, Eötvös achieved a distinguished position. His readiness in debate, his fine presence, his liter-

ary attainments, his rank, all combined to give him great influence in the senate and in Hungarian society. But whatever may have been his merit as an orator and a politician, it was eclipsed by his fame as a novelist. The financial crisis of 1841 having deprived his family of the greater part of their fortune, he resorted to writing as a means of support, and began to publish a tale in numbers, under the title of *A Falu Jegyzője* ("The Village Notary"), in which he boldly exposed the abuses connected with the rule of the nobles in the counties. This novel had a marvellous success. A second edition appeared at Pesth in 1851, and a translation was published in England with a preface by Mr. F. Pulszky, to whom the work was originally dedicated. In 1847 he produced a new novel on the revolt of the peasantry in 1514, entitled *Magyarország 1514-ben* ("Hungary in 1514"). During this time he also exerted an influence through the newspaper press. His articles in the *Pesti Hirlap*, especially on centralization, of which he became the champion, while Kossuth defended the autonomy of the counties, were collected in 1846 in a volume at Leipsic under the title of "Reform." After the outbreak of 1848 Eötvös was appointed minister of public instruction under the Batthyány administration. He brought forward a comprehensive measure for the improvement of education, which was strenuously opposed upon sectarian grounds, but was warmly supported by Kossuth and adopted by the diet. Eötvös, however, withdrew from the cabinet on occasion of the assassination of Count Lamberg, and retired to Munich until 1851, when he returned to his native country. His most important and recent work is on the "Influence of the Leading Ideas of the 19th Century on the State" (2 vols., 1851 and 1854, Hungarian and German by the author), in which he expresses his confidence in the faithfulness of the age to humanitarian ideas, notwithstanding its utilitarianism.

EPACT (Gr. *επακτος*, added), a number introduced into the Gregorian calendar, intended to express the moon's age (in days) on Jan. 1, and thus to determine its age on March 21. Easter Sunday was appointed by the council of Nice to be the first Sunday after the first full moon following the vernal equinox. But, in the church, this Sunday is found by a formula which is not strictly correct, so that Easter is sometimes on a different Sunday from what the direction of the council of Nice would lead to, if the equinox and full moon were sought by astronomical tables. The epact usually gives the moon's age one or two days too great. To find the epact: From 11 times the golden number subtract 10, and divide by 30; the remainder is the epact if the date is in the 17th century. For the 18th and 19th centuries subtract one from this remainder; for the 20th and 21st subtract 2. Subtract the epact from 24 (or, if it is a larger number than 24, from 54), and the remainder will show the number of days from the 21st of March to the next ecclesiastical (not

l) full moon; and the following Sunday (covered by the dominical letter) will be a Sunday.

EPAMINONDAS, a Theban general and statesman, born in the last quarter of the 5th century B. C., died on the battle field of Mantinea in 362. He was the son of Polymnis, of a distinguished though rather poor Theban family, numbered among those that were believed to have sprung from the dragon's teeth sown by Cadmus. Endowed with rare gifts and perseverance, he acquired not only that bodily strength and military skill which were regarded as essential in Theban education, but those accomplishments which belonged to a cultivated society of Athens, but were little valued for in the home of Pindar. He schooled his higher faculties by diligent study and intercourse with philosophers, one of whom, the Megarean Lysis, a Tarentine exile who closed his days in Thebes, he revered as a father. But his philosophy with Epaminondas was not only a relative study, he modelled his life accordingly. Self-possessed, modest, indifferent to wealth, he despised riches, lived poor when at the height of power, and was a strict observer of laws, though often acting as a diplomatist.

Pelopidas, a man of congenial patriotism, was as early connected by the ties of friendship, though the date of the battle in which he saved the life of his friend cannot be ascertained. When Pelopidas, after the treacherous occupation of the Cadmea, the citadel of Thebes, by the Spartan general Phœbidas, and the execution of the leader of the patriotic party, Ismenias, conspired with a number of his colleagues the polemarchs, Epaminondas tried to dissuade his friends from their rash attempt; but when the first deed of violence was done (379), and the contest transferred from the houses of Archias and Leontiades to the open market place, he immediately joined the exiles in arms and incited the citizens to storm the Cadmea. But the commander of the Spartan garrison evacuated the city on capitulation. This revolution opened the political career of Epaminondas; and though scarcely mentioned in the following period of years, during which the military strength and political influence of Thebes were gradually developed, the great trusts with which he was honored in 371, both as a diplomatist and as a general, prove that his services to his country were highly appreciated. At the

congress held that year in Sparta, for the purpose of regulating the affairs of Greece, he defended the rights of Thebes and its ascendancy in Boeotia to their utmost extent, arguing on taking the oath of the new treaty for Thebes separately, but for that city as a member of the Boeotian confederation. When Agesilaus, the energetic king of Sparta, arose in defence of the autonomy of the Boeotian confederation, Epaminondas claimed the same for the cities of Laconia. The Thebans were

excluded from the treaty, and war speedily commenced. Twenty days after the debate at Sparta the contending armies met at Leuctra. Cleombrotus, the colleague of Agesilaus, commanded the Spartans and their allies, Epaminondas was Boeotarch, and Pelopidas led the sacred band, lately organized and already distinguished. Departing from the usual habit of drawing up the armies in line for a general engagement, Epaminondas, whose numbers were inferior to those of his adversary, arrayed his best troops on his left wing to the depth of 50 shields, with the sacred band in front, advanced *en échelon*, keeping his right and centre a little to the rear, and attacked the Spartan right, where Cleombrotus and his chief officers were stationed. The shock was terrible, and after a short struggle the Thebans gained a decisive victory. Four hundred Spartans with their king, and 1,000 other Lacedæmonians, were among the dead. The whole of Greece, including Thebes, was surprised by this issue, so fatal to the might and glory of Sparta, though she still obeyed her laws, mourning not the victims but the survivors of Leuctra. Epaminondas pursued and strengthened his success by promoting the union of Arcadia and the foundation of Megalopolis, as its centre, against Sparta, and in 369 invaded the Peloponnesus together with some other Theban commanders. As their term of service drew to a close, he and Pelopidas persuaded their colleagues to continue the campaign, and to penetrate into the heart of Laconia. This province was now ravaged; Sparta itself barely escaped being taken; Messenia, its oppressed dependency, was restored to liberty, with a new capital, Messene, about the site of the ancient Ithome. An army from Athens, which had marched to assist Sparta, failed to check the return of the victorious Thebans through the isthmus. This being achieved, Epaminondas appeared before the tribunal of Thebes to answer for retaining his office beyond the legal time, and was acquitted amid the acclamations of the people. In the spring of the following year he again penetrated into the Peloponnesus, but on his return failed in an attempt on Corinth, being repulsed by the Athenians. He subsequently accompanied the army sent to Thessaly to rescue Pelopidas, who had fallen into the hands of Alexander, the tyrant of Pheræ. This expedition failed, but Epaminondas saved the army, and having been made commander of a new expedition for the same purpose (367), succeeded in delivering his friend without striking a blow. His influence at home, however, often attacked by enemies, was not always strong enough to moderate the aggressive spirit of his state, which he had raised to the leadership of Greece. Strengthened by a navy and an alliance with Persia, the former the work of Epaminondas, the latter of Pelopidas, the Thebans oppressed their neighbors of Thessaly, their confederates of Boeotia, and their allies of Arcadia, and evinced not only an overbearing spirit at every international complication,

but also wanton cruelty in the destruction of the revolted Orchomenus in Arcadia. The consequence was a defection of nearly all the Arcadians, and a strong southern coalition against Thebes. Rapid and decisive action alone could save the supremacy of that state, and Epaminondas, therefore, again invaded the Peloponnesus at the head of an imposing army of Bœotians, Eubœans, Thessalians, and Locrians, which was soon joined by troops from Sicyon, Tegea, Megalopolis, Messenia, and Argos. The enemy concentrated his force at Mantinea. This was composed mainly of Achæans, Eleans, and Arcadians, while the old Agesilaus was approaching from Sparta, and the Athenian contingent was expected. Having vainly tried to provoke the allies to action before the arrival of the Spartans and Athenians, Epaminondas, aware of the circuitous route of Agesilaus, made a rapid night march from Tegea to surprise Sparta, which was saved, however, by Agesilaus being in time apprised of the danger, and by the admirable bravery of his son Archidamus and some other youths. Epaminondas now turned to surprise Mantinea while the enemy marched to the rescue of Sparta, but the arrival of the Athenians frustrated this attempt also. He finally determined on a pitched battle, which was fought on the plain between Mantinea and Tegea (362). The plan of the Theban general was similar to that adopted at Leuctra, and the issue would probably have been the same, had not his advance been interrupted by a javelin wound. He fell with the point of the broken spear sticking in his breast. He was still alive, but the extraction of the spear head would have terminated his pain with his life. Having been assured that his shield was not lost and that the Thebans were victorious, he inquired for two of his generals, but was told that they were dead. "Then let Thebes make peace with the enemy," said he, and drew out the weapon with his own hand. In reply to his friends, who regretted that he died childless, he said: "I leave two fair daughters, Leuctra and Mantinea." Epaminondas ranks among the greatest men of Greece, and is described by Nepos, in accordance with the concurring testimonies of the Greek historians, as a man adorned with every virtue and stained by no vice.

EPANOMERIA, a remarkable town in the island of Santorin, the ancient Thera, in the Grecian archipelago. It is situated on the face and edges of a tall cliff at the extremity of a promontory on the N. W. end of the island. The houses, many of which are excavated from the rock, are placed one above another, 15 or 20 deep, the lowest being 400 feet above the water. They are approached by means of a winding road and staircases cut in the cliff, and reaching from the base to the summit. Viewed from the sea, nothing can be more striking than the appearance of this town, with its dwellings high above the masts of the largest ships, or perched on the edges of frightful precipices. On the summit the scene is scarcely less singular, the

road there in many places passing over habitations the existence of which is denoted only by chimneys jutting up on each side.

EPAULETTE (Fr. *épaule*, shoulder), an ornamental badge, or mark of distinction, worn on the shoulder by military men. It originated under Louis XIV., from the ribbon which held the sword belt in place on the shoulder. Epaulletes are worn either on one shoulder or both, by both naval and military officers, and are varied to denote distinctions of rank.

EPÉE, CHARLES MICHEL, abbé de l', an instructor of the deaf and dumb, born at Versailles, France, Nov. 5, 1712, died Dec. 23, 1789. On arriving at manhood he commenced the study of theology, and gave in his adhesion to the doctrines of the Jansenists, on which account his bishop refused him ordination, unless he would sign a certain formula of doctrine. This he would not consent to do, and though subsequently admitted to deacon's orders, he was told that he need not aspire to any higher ordination. Full of grief at this decision, he became a student of law and was admitted to the bar; but at this juncture, his old friend, M. de Bossuet, a nephew of the great pulpit orator, having been promoted to the see of Troyes, offered him a canonry in his cathedral, and admitted him to priest's orders. He fulfilled his new duties with zeal and propriety; but hardly had he established himself in what he hoped was his life-work, before his kind patron died, and his place was filled by a Jesuit bishop, through whose influence he was deposed from the priesthood. It was while depressed by this sudden change in his prospects that De l'Épée's attention was first called to the unfortunate class to whose welfare he subsequently devoted his life. Calling one day upon a neighbor, he found that she had two daughters who were deaf and dumb, that a benevolent priest had endeavored to convey some ideas to them by pictures, but that he was dead, and there was no one who could teach them. Touched by their misfortune, he resolved to undertake their instruction. Up to this time the only successful attempts at instructing the deaf and dumb had been by the process of articulation. A few persons, less than 50 in all, in a period of 270 years, had been with infinite pains taught to pronounce words indifferently well; in most cases their understanding of the meaning of words thus communicated was imperfect; but it was reserved for De l'Épée to inaugurate the system of instruction by natural signs. Pereira, Wallis, Dalgarno, Bonet, and Ponce had instructed a few sons of rich men, and men of high rank, but he sought only the improvement of those who could not pay for instruction. When he commenced his labors as a teacher of deaf mutes, De l'Épée was not aware that any works had been written upon the subject. Some time after he accidentally obtained a copy of Bonet's *Reduccion de las Letras* in Spanish, and learned that language in order to read it. But the idea of using the natural signs and gestures to communicate in-

formation to the deaf mute was unquestionably original with him. It was the application of a principle which, in general terms, he had acquired in youth, that ideas were substantive, and had no necessary connection with words written or spoken; to find the means of presenting ideas to the mind of the deaf mute, without the intervention of words, was the problem which De l'Épée set himself to solve, and in the gestures and signs by which mutes were accustomed to convey their thoughts and wishes to others, he found the key to its solution. To extend, amplify, and systematize this language of signs, was thenceforth his work, and it was well done. Others have since introduced many and important improvements, but the foundation was laid and the walls of the superstructure reared by him. From 1755, the date of his first establishment of a school for deaf mutes, till his death in 1789, a period of 34 years, he supported the school entirely at his own expense, receiving no remuneration from either public or private sources. As his school soon became large, and his patrimony was but small, he was compelled to exercise the most rigid economy. Even in his 76th year he insisted on depriving himself of fire in his own room in order to sustain his school. But though thus prudent and economical in his own expenditure, he would not receive the children of those who were able to remunerate him, nor would he accept even from crowned heads any pension, present, or gratuity. When the ambassador of Catharine II. intimated to him that his royal mistress desired to make him some valuable gifts for his service to the unfortunate, he asked, as a special favor, that she would send him some ignorant deaf and dumb child from her dominions whom he might educate. To Joseph II. of Austria, who pressed him to receive the annual revenues of one of his estates, he replied by the request that he would send him some person whom he might instruct in the art of teaching the deaf and dumb, and who might then establish an institution for them in Austria. From the first his methods of instruction were public; in this he was imitated only by Heinicke, a man of like spirit. Wallis, Pereira, and Braidwood all kept their processes secret, designing to leave them as heirlooms to their families. A bronze statue has been erected to the memory of De l'Épée at Versailles, and a bass-relief placed in the church of St. Sulpice, by citizens of Sweden. In the imperial institute of the deaf and dumb at Paris, a tablet commemorates his worth and his noble deeds. In 1855 the centennial anniversary of the establishment of his school for deaf mutes was celebrated at Paris, and was largely attended by delegations from institutions for the deaf and dumb in other countries of Europe.

EPIERIES, a town of northern Hungary, on the Tarcza, capital of the county of Sáros, in the district of Kaschau; pop. about 9,000. It is one of the most ancient and interesting, and, after Kaschau, the most beautiful of the towns of

Upper Hungary. In 1687 the imperial general Caraffa established here the famous bloody tribunal which caused the torturing and execution of a very large number of patriots, especially Protestants. The executions took place on the public square before the windows of the general, and death on the gallows was regarded as comparatively mild and merciful. In 1848 and 1849 Eperies was successively in the possession of the revolutionists, of the Austrians, and of the Russians.

EPERNAY, an ancient French town, capital of the arrondissement of the same name, in the department of Marne, situated in a fertile valley on the left bank of the river Marne, 20 m. from Châlons, on the railway from Paris to Strasbourg; pop. in 1856, 9,182. It presents a lively, bustling appearance, and has a number of manufactories, a theatre, a public library of 10,000 volumes, and a fine city hall. It is the great entrepot of the trade in Champagne wine.

EPHAIH, one of the measures in use among the Hebrews, both for things dry and liquid. As a liquid measure, it was the same as the bath or firkin, and contained about $7\frac{1}{2}$ gallons. As a dry or hollow measure, it was one-tenth of the homer, and was equal to 10 omers or gomers. It held a little more than $1\frac{1}{2}$ bushels of our measure. There was, however, a difference between the measures, weights, &c., of the Hebrews before and after the captivity.

EPHEMERA (Gr. *εφημερος*, that which lasts a day), the name given by Linnæus to a genus of insects of the order *neuroptera*, so named from their appearing in the winged state only for the short period of a day, though in the larva and nymph states they are said to live beneath the surface of the water for 2 or 3 years. Appearing above this, in the air, generally toward the evening in fine summer weather, they provide for the continuation of their race and die. Though but frail and delicate insects, they have been found, in certain districts in France, covering the ground in such enormous numbers that they have been collected by cart loads for manure. One species, the *ephe-mera albi pennis*, or white-winged, is sometimes seen in such quantities by the banks of rivers, that they whiten the air and the ground like drifting snow.

EPHESIANS, **EPISTLE TO THE**, one of the canonical books of the New Testament, written by St. Paul during the earlier part of his imprisonment in Rome (about A. D. 62), and commonly believed to have been addressed to the church at Ephesus, though Marcion, Grotius, and others have maintained that it is the epistle to the church in Laodicea which is usually supposed to have been lost, and Archbishop Usher that it was a circular letter intended for no church in particular. This epistle is written, says Macknight, as it were in a rapture, and expresses in an elevated style the fulness of the apostle's joy on learning the steadfast faith of the church which he had founded. Without presenting any strictly marked divisions, it treats especially of the mystery and blessedness

of the scheme of redemption, and closes with exhortations to various duties, to fortitude, watchfulness, and prayer.

EPHESUS, one of the 12 Ionian cities of Asia Minor, situated on the western coast, near the mouth of the Caystrus. According to the legends it was founded by the Amazons, when they descended from the banks of the Thermodon to combat Theseus. It was inhabited by the Carians and Leleges, who were expelled and succeeded by Ionian colonies under Androclus, son of Codrus, the last king of Athens. The Greek genius of the new inhabitants, the mildness of the climate, the richness of the soil, the favorable location for commerce, and above all the worship of Diana, which was said to have been instituted there by the Amazons, made this city the most important metropolis of western Asia. It was governed by a senate and by deputies, and maintained its independence till the reign of Cræsus of Lydia, who attached it to his kingdom. It then passed successively under the power of Persia, Macedon, and Rome. The Romans governed it as the capital of western Asia, by their proconsuls, and made it the centre of a great commerce. It was called by Pliny "the light of Asia." It declined early in the middle ages, and at present its site is covered with rubbish and vegetation, and there remains only the remembrance of its past history and of its magnificent temple of Diana. Ephesus was one of the cities which claimed the honor of having given birth to Homer. It was the birthplace of the famous painter Parrhasius, and perhaps of Apelles, of the philosophers Heraclitus and Hermodorus, and of the poet Hipponax, the inventor of the parody. But its chief glory and ornament was its magnificent temple, soon after the destruction of which by the Goths, the city itself went to decay. The first foundation of the temple was anterior to the arrival of the Ionian colonies in Asia Minor, who found the worship of Artemis or Diana already established there. It was enlarged and 7 times restored at the expense of all Asia, and became one of the 7 wonders of the world. Its length was 425 feet, and its width 220 feet. Its roof of cedar, resting on a marble entablature, was supported by 127 or 128 columns, 60 feet high, each of them, according to Pliny, the gift of a king. The statue of the goddess Diana was of ivory, and furnished with exquisitely wrought golden ornaments. This was the largest of the Greek temples, occupying more than 4 times the area of the Parthenon at Athens. The architectural beauty of the interior was heightened by the presence of the masterpieces of the most eminent artists, and the wealth which it contained was equalled only by that at Delphi. During the night on which Alexander was born, in 356, this magnificent structure was burned to the ground, by the caprice of a certain Erostratus, who avowed that he had no other object than to immortalize his name. A little later, when the Macedonian king had passed the Granicus, he offered to rebuild the temple with its former magnificence, if he might

be allowed to inscribe his own name upon the frontispiece. The pride of the Ephesians rejected the offer, and it was restored by the combined and enthusiastic efforts of all the Ionian cities, under the direction of the architect Dinocrates. The right of asylum extended for a stadium around it; but this privilege, which caused the town to be overrun with criminals, was abolished by Augustus. Under the emperors the medals of Ephesus bore a representation of the temple. Ephesus was visited A. D. 54 by St. Paul, whose preaching occasioned a famous tumult, and to the Christians there he directed one of his epistles. It was the seat of one of "the seven churches which are in Asia," and the 34 œcumenical council was held there in 431, in the reign of Theodosius II. Upon a part of the site of ancient Ephesus is the Turkish village of Aya Soolook, and the entire disappearance of so huge a mass as the temple of Diana can only be accounted for by supposing that the materials were carried away and incorporated into other buildings. (See "Ephesus and the Temple of Diana," by Edward Falkener, London, 1857.)

EPHOD, one of the articles of the official dress worn by the Hebrew priests, consisting of two parts, one covering the breast and the other the back, and both united upon the shoulders, and sometimes described as thrown over the shoulders, hanging down before, crossed upon the breast, and then carried round the waist to serve as a girdle for the robe. It was of two kinds: one of plain linen, for the priests; and the other, for the high priest, "of gold, and blue, and purple, and scarlet, and fine twined linen," richly embroidered. On the shoulders of the high priest's ephod were two onyx stones, set in gold, having engraved on them the names of the 12 tribes, 6 on each stone; and where it crossed the breast was a square ornament, called the pectoral or breastplate, in which were set 12 precious stones, each bearing the name of one of the 12 tribes engraved on it. The girdle was probably woven with the ephod, or upon it, so that coming out from it, on each side, it was brought round under the arms like a sash, and tied on the breast, thus securing both the ephod and the robe. The ephod, or something like it, and called by the same name, was worn by others beside the priests.

EPHORI (Gr. *ἐφοροι*, to oversee), popular magistrates at Sparta from the earliest times. The origin of the office was variously ascribed to Lycurgus, to Theopompus, and to the era of the first Messenian war, but it seems to have been too ancient for its institution to be historically traced. The authority of the ephori was designed as a counterpoise to that of the kings and council, and hence Cicero has instituted a comparison between the Spartan ephoralty and the Roman tribunate. They were 5 in number, and chosen from and by the people without any qualification of age or property. The mode of their election is not now known. Aristotle calls it puerile, and it is supposed to have been by some species of lot. They held their office

for one year, entering upon it at the autumnal solstice, the beginning of the Lacedæmonian year. They met daily and took their meals together, in the building in which foreigners and ambassadors were entertained. They had judicial authority in civil cases, and the power to make scrutinies into the conduct of all magistrates. In early times the privileges of the office were such that in the hands of able men it might be made an instrument of unlimited power, and in later times even the kings were called before its tribunal, and the assemblies of the people were convened only by its authority. During the Peloponnesian war the kings became completely under the control of the ephori, so that the latter received foreign ambassadors, subscribed treaties of peace, and sent out armies; and even on the battle field the king was attended by 2 ephori as councillors of war. The ephoralty is thought by Müller to have been the cause of the instability and final dissolution of the Spartan state. The kings were obliged to court popular favor in order to uphold their power, and thus, contrary to the spirit of the Spartan constitution, the government became a democracy instead of an aristocracy. The ephori became at length associated with all opposition to the extension of popular privileges, and the office was abolished for a time by Agis and Cleomenes. It was, however, restored by the Romans.

EPHRAEM SYRUS (the Syrian saint), the most prominent instructor of the old Syrian church, and one of the most prolific theological writers of the early Christian church in general, died probably in 878. He was first teacher at a school in Nisibis, and afterward took up his abode at Edessa, which was already becoming the centre of Syrian scholarship. He subsequently lived near Edessa as a hermit, devoting all his time to prayer, the study of the Bible, and the writing of theological works against the remains of paganism in his country, and the heresies of his times. It is believed that he founded at Edessa a theological school, and spent 8 years in Egypt, where he is said to have become acquainted with Basil the Great, to have been ordained by him a deacon, and to have written works in the Coptic language. He was called by his countrymen the cithara of the Holy Ghost, and, because he transplanted Greek learning into the Syrian church, the prophet of the Syrians. His ascetic and exegetic works were valued in the early church so highly, that passages were frequently read from them at the religious meetings. Hymns and prayers which are ascribed to him are still in use in the Chaldean, Syrian, and Maronite churches. Some of his numerous works are extant in the original Syriac, many others exist in Greek, Latin, and Armenian translations, and many are lost. The most complete edition was published at Rome from 1732 to 1746, in 6 volumes, 3 of which contain the works in Syriac with a Latin translation, 3 the Greek texts. A good German translation of a large portion of his works was

published by Pius Zingerle, at Innsbruck, from 1830 to 1838. A tasteful English translation of several choice hymns, songs, and homilies was made by Henry Burgess ("Select Metrical Hymns and Homilies of Ephraem Syrus," 2 vols. London, 1853). A new complete edition is expected to be published soon in Germany by Alslieben, who in 1853 wrote a life of Ephraem.

EPHRAIM, a city mentioned by St. John as "near to the wilderness," with no further clue to its position. The wilderness referred to is doubtless the wild and rocky desert of Judæa, and the town is located by Eusebius 8 m. and by St. Jerome 20 m. N. of Jerusalem. Dr. Robinson identifies it with the modern Taiyibeh, 5 m. N. E. from Bethel, and overlooking the desert country which lies between it and the valley of the Jordan.

EPHRAIM, 2d son of Joseph, the founder of the tribe of Ephraim. This tribe occupied one of the finest and most fruitful territories of Palestine, in the very centre of the land. It included most of the province afterward called Samaria, and contained many of the historically most distinguished places of Palestine between the Jordan and the Mediterranean, having the tribes of Dan and Benjamin on the S. and of Manasseh on the N. It was crossed by the mountain range bearing its name. The tribe of Ephraim, numerous and influential, often appears as the representative of the 10 tribes, or the northern Hebrew state, both in historical and prophetic passages of the Scriptures. It held for a long time the ark and the tabernacle at Shiloh.

EPIO (Gr. *ἐπικός*, from *επος*, speech), one of the 3 styles of poetical composition, distinguished from the lyric by representing action rather than emotion, and from the dramatic by representing events through narration instead of through imitative action. In a general sense, it may embrace all poetry and fiction that are chiefly of a narrative character, as the mediæval metrical romances and the modern novels; but it is more properly applied to poems which follow the history of national or mythological events of momentous interest. The epic gives external and plastic views of life, deals with masses of men animated by the same political or religious idea, and illustrates the character and problem of a nation, or civilization, unlike the drama, which treats of individual character and fortunes. Thus the conquest of Troy, the theme of Homer's "Iliad," was an object of national and religious enthusiasm to all the Greeks; the conquest of Jerusalem, the subject of Tasso's *Gerusalemme Liberata*, was a matter of highest interest to all Christendom; and the sacred subjects in Dante's *Divina Commedia* and in Milton's "Paradise Lost" may be regarded as typical of Christian thought and civilization. The *Ramayana* and the *Mahabharata* are celebrated ancient Indian epics, and the French romances of the *trouvères* and the German *Nibelungenlied* are of an epical character. Other epic poems are the Persian *Shah-*

Namck of Firdusi, the "Odyssey" of Homer, and the *Argonautica* of Apollonius in Greek; the "Æneid" of Virgil, the "Pharsalia" of Lucan, and the *Punica* of Silius Italicus, in Latin; the "Lusiad" of Camoëns in Portuguese; the *Araucana* of Ercilla in Spanish; the *Orlando Furioso* of Ariosto in Italian; the *Henriade* of Voltaire in French; and the "Messias" of Klopstock in German. Goethe's *Hermann und Dorothea* also may be called a domestic epic.

EPICHRMUS, a Greek dramatic poet, the founder of the old Doric comedy, born on the island of Cos about 540, died in 450, or, according to Lucian, 443 B. C. He repaired to Syracuse in 484 or 483 B. C., where he passed the remainder of his life, and at the court of Hiero he made acquaintance with several poets, among whom was Æschylus, the father of Greek tragedy. He conceived the idea of transforming the loosely constructed farces of which the Sicilian comedy consisted into pieces as regular and correct as the Athenian tragedies. He effected as great a reform in comedy as Æschylus in tragedy, diminishing the number of the actors, introducing a more elegant and poetic language and a more elaborate plot. He was the author of 52, or, according to others, of 35 comedies, of which only the titles remain. His works were especially esteemed by Plato, who has made many quotations from them.

EPICLETUS, a Roman stoic philosopher, born in Hierapolis, in Phrygia, in the first century of our era, died near the middle of the 2d century. He was in his youth a slave of Epaphroditus, who was one of the guards of Nero. It was under the training of this cruel master that he developed the admirable patience for which he was distinguished. Epaphroditus having once struck him heavily upon the leg, he said to his master: "You will break my leg." The prediction was speedily fulfilled, when the philosophic slave said again calmly: "Did not I tell you you would break it?" This extreme insensibility to pain was a fundamental principle in the philosophy of Epictetus. He became a freed man, though neither the cause nor the time of this change in his condition is known. He was involved in the proscription by which Domitian banished all philosophers from Rome, and retired to Nicopolis in Epirus, where he opened a school of stoicism, and held those conversations which have been preserved to us in the "Manual" and "Philosophical Lectures" which were compiled from his discourses by his pupil Arrian. He probably returned to Rome after the death of Domitian, but no other details of his life have been preserved. Like the other stoic philosophers, he taught by his example. He esteemed philosophy to be neither profound speculation nor eloquent discourse, but the love and practice of virtue. The few Romans who cultivated philosophy were all eclectics and Platonists in metaphysics and stoics in moral philosophy. Ethics was the only part of philosophy in which they took a serious inter-

est, and with great faith in Roman manners and society they cared little for the solution of metaphysical problems. Seneca, Epictetus, and Marcus Aurelius were only moralists, and their stoicism was only Roman heroism reduced to a system. Their philosophy was a scheme of practical duties, and, regarded abstractly, was neither thorough nor consistent. Thus they proclaimed the reason, but reason with them became merged in calm and unswerving purpose. They demonstrated a providence, but their providence was destiny. The teachings of Epictetus are summed up in the formula: "Bear and forbear." Recognizing only will and reason, his highest conception of life was to be passionless in whatever circumstances. "Man," he said, "is but a pilot; observe the star, hold the rudder, and be not distracted on thy way." Epictetus himself is supposed to have committed nothing to writing. The best edition of all the remaining works of Arrian is that of Schweighäuser, in the collection entitled *Epictetæ Philosophiæ Monumenta*, 5 vols. 8vo., Leipsic, 1800). They were well translated into English by Elizabeth Carter (London, 1758).

EPICURUS, a Grecian philosopher, born in the island of Samos in 342, died in 270 B. C. The son of a colonist from Gargettus, a deme of Attica, he received his early education on his native island. When 18 years of age he went to Athens, where he became a pupil of Pamphilus, and an admirer of the doctrines of Democritus. In his 23d year he returned to his family, then living at Colophon, traveled for several years, and finally in his 30th year settled at Athens. There he established a school of philosophy, and his fame soon attracted a great number of scholars. With them he constituted a community which has always been considered as a model of its kind. He enjoyed the respect and love of his followers to such a degree that his sayings had almost the value of oracles. No other ancient school of philosophy has evinced a cohesive power equal to that of Epicurus. Epicureanism has, in the course of time, become almost a synonyme of sensualism, or at least a refined voluptuousness, while nothing was further from the meaning of his doctrines. It is true that he taught *eudaimonia* to be the highest end and purpose of human life, but this word was intended to designate a state of supreme mental bliss, to be attained only by temperance, chastity, and a healthy intellectual development. That bliss, consisting in a perfect repose of mind, in an equilibrium of all mental faculties and passions, is perhaps not very different from the state of mind which the stoics considered as the acme of human perfection, although they were the most unrelenting adversaries of Epicureanism. Personally Epicurus was a man of unsullied morality. He was a most voluminous writer (*πολυγραφωτατος*), says Diogenes Laërtius, who estimates the number of his works at 300 or more. He boasted of having never used any quotations in order to

swell his volumes. Few of his writings have been preserved, but a full analysis of his doctrines is to be found in Diogenes Laërtius, and this, taken in connection with numerous passages in the writings of Lucretius, Cicero, Pliny, and others, gives us a full insight into his philosophical system. Within the present century a fragment of his book on nature has been recovered from the ruins of Herculaneum, and published by Orelli (Leipsic, 1818). Philosophy, according to Epicurus, is the exertion to obtain happiness by reasoning. The supreme bliss (*ευδαιμονεια*) is enjoyment and perfect freedom from pain. Enjoyment is either passive, when a perfect repose of mind is its principal condition, or active (*ηδονη καταστηματικη* and *ευκινησια*). The former is preferable to the latter. It is the state of absolute absence of pain. Sensations, whether agreeable or disagreeable, are of the same nature; it is only the consequences which constitute their difference. Hence it is the province of reason to discern them according to the ultimate effect they produce. Virtue in itself, irrespective of its consequences, has no value. It is merely the result of wisdom and sagacity (*φρονησις*), which prove to man that happiness is only to be attained by charity, peacefulness, temperance, patience, self-command. Human or natural rights are merely restraints of individual action, imposed by the necessities of social life. It is self-interest which enjoins us to do right. The repose of mind which constitutes human happiness being continuously disturbed by the uncertainty of the relations of man to the universe and divinity, Epicurus proposed to dispel that uncertainty by a reconstruction of the atomistic theories of Democritus, in the following manner: Nothing comes from nothing. That which exists can never be annihilated. All matter consists of atoms, and these are unchangeable and indivisible, although filling a certain space. Beside shape, volume, gravity, and motion, they have no properties. Their number is infinite, their shape indefinitely varied. The universe is infinite, and, considered as a unit, unchangeable, for the aggregate quantity of matter remains always the same, however its component parts may combine. The universe cannot be the product of divine action, or else the existence of evil could not be accounted for. The atoms blindly drifting through infinite space, and declining somewhat from their course (through an accidental cause, the nature of which Epicurus fails to explain), are mingled together, shove and push one another (the chaos), until the homogeneous ones associate. The light round atoms (the atoms of fire) are pushed upward, where they form the celestial bodies; those which are somewhat heavier form the air, while the heaviest are precipitated as water and earth. In a similar way the different objects on earth are formed. But the whole process is merely an accidental aggregation of atoms; higher ends and divine laws are mere inventions of the human mind. The psychology of Epicu-

rus flows directly from his natural philosophy. The human soul, according to him, is a delicate and extremely mobile substance, consisting of the minutest round atoms. Its elements are warmth, air, breath, and another nameless substance on which sensibility depends. While the 3 first named are distributed through the whole body, the 4th has its seat principally in the pectoral cavity, and is, as it were, the soul of the soul. The soul is not immortal; nevertheless death is by no means to be considered as an evil, since there remains no consciousness of annihilation after death. Of all objects filling space infinitely delicate images are secreted. These images, coming into contact with the organs of sense, create perceptions. The conceptions of imagination are arbitrary combinations of such delicate images of real objects. By frequent perceptions the human mind attains to general abstractions, which are merely collective conceptions of the features common to a larger or smaller number of individual perceptions. Since the senses are the receivers of mechanical secretions of objects (images), the knowledge obtained through them is real and objective, the only correct standard of truth; but the workings of imagination, being likewise the result of sensitive perception, although an indirect one, point also to existing realities. Hence it follows that the universality of the belief in the existence of a Supreme Being is proof conclusive of such existence. The gods are living beings of human shape but colossal proportions. They also consist of atoms. They are immortal, although their bodies are similar to the human body. This contradiction is explained by a certain equilibrium of contrasts in the universe (*ισονομια*). The gods are living in eternal bliss, that is to say, in absolute inactivity, in the quiet enjoyment of sublime wisdom and virtue. The spaces between the different celestial bodies (*intermundia*) are the seats of the gods.

EPICYCLE (Gr. *επι*, upon, and *κυκλος*, circle), the path of a point moving uniformly in the circumference of a circle, whose centre moves uniformly in the circumference of a second circle, whose centre may move in the circumference of a third, &c. The epicycle is famous in the history of science, as the first attempted hypothesis to explain the irregularity of the planetary motion. The discussion of this curve was an admirable mathematical drill to the early astronomers. In modern times, the epicycle is used in order to express in a few words the numerical value of periodical functions of an unknown law. Thus if the fluctuations of the thermometer for a day be observed, the size and initial position of several circles may be calculated, such that if the centre of the 2d move uniformly round the 1st once in 24 hours, the 3d round the 2d once in 12 hours, the 4th round the 3d once in 8 hours, &c., the height of the centre of the 4th or 5th circle will be the same as that of the mercury.

EPICYCLOID, the path of a point in the cir-

cumference of a circle rolling upon the circumference of another circle. If the rolling circle rolls upon the inside of the stationary circle, the curve is called a hypocycloid. When the point generating the curve is not in the circumference of the rolling circle, but inside of it on a radius, or outside on a radius prolonged, the curves are called epitrochoids or hypotrochoids (Gr. *τροχαιδης*, circular). Epicycloids and hypocycloids are remarkable from the fact that whenever the diameters of the two circles are in exact numerical ratio, the length of the curve is also in numerical ratio to the diameters. They also contain several curves interesting from their physical properties; for instance, if the circles are of equal size, the epicycloid becomes the cardioid, which is the caustic produced by reflection from a circle, when the luminous point is in the circumference; if the rolling circle is half the diameter of the stationary circle, the epicycloid is the caustic produced by the reflection of parallel rays from the inside of a circle, while the hypocycloid becomes a straight line.

EPIDAUROS (the modern Epidavro), an ancient city of Greece, in Argolis, on the Saronic gulf, enclosed by high mountains, and which formed, together with its small adjacent territory, an independent state. According to Strabo, it was founded by a Carian colony, and originally named Epicarus. It subsequently received an Argive colony, and became a part of the Doric league, of which Argos was the head. It had an aristocratic constitution, was an important commercial city, and colonized Ægina; but it rapidly declined in the 6th century B. C., its commerce passing into the hands of the Æginetans. It was chiefly distinguished for its splendid temple of Æsculapius, bearing the inscription: "Let only pure souls enter here," which stood a little to the west of the city, on the road to Argos, between two mountains, in a thickly wooded grove, in which it was unlawful for any one to be born or to die. The temple was near the centre of this sacred grove, and contained a chryselephantine statue of the god, which represented him as seated upon a throne, holding in one hand the head of a serpent, and in the other a staff, while a dog lay at his feet. Near the temple there was the Tholos, a circular structure, containing medicines for all diseases, a theatre, the bath of Æsculapius, and other temples dedicated to Diana, Venus, Themis, Hygeia, and Apollo. Pilgrimages were made to this temple by the sick, and every 4 years a festival, with musical and gymnastic exercises, was here celebrated. The wealth of this temple became the plunder of Roman conquerors. Some of its foundations are still traced, and the theatre which was adjacent to it is one of the best preserved of all the old Greek edifices. The modern Epidavro is a small village, noted as the place of assembly of the first Greek congress in 1821.

EPIDEMIC DISEASES (Gr. *επι*, upon, and *δημος*, people) are those which attack at the same time a great number of persons in a

given locality, depending on some temporary, accidental, and generally inappreciable cause; differing in this respect from endemic diseases, or those developed under the influence of some constant or periodic cause. Many diseases, ordinarily sporadic, may become epidemic under certain ill-understood conditions; or some new disease, introduced by contagion or other favorable circumstances, may spread epidemically. The limits of this work will not permit even an allusion to the phenomena of development, progress, and treatment of this great category of diseases; the investigation of their causes is extremely difficult, and has given rise to the most fanciful, absurd, and contradictory opinions; and the solution of the problem of a single one involves a rigorous examination of the constitution of the air, the conformation of the soil, the nature of the food, and even the social habits of a country. The progressive sciences of meteorology and physical geography will probably soon throw additional light upon these difficult questions; the most important sanitary and hygienic improvements often depend upon the removal of apparently trifling causes of disease, and the consideration of this matter is now actively engaging the attention of both physicians and municipal authorities. Having ascertained the cause, or the epidemic tendency of the season, the treatment must depend on the nature of the disease and the constitution of the patient; even when remedial measures seem powerless, the physician can do much to check an epidemic by inspiring confidence and moral courage, and by withdrawing the attention of a community from the continual consideration of any supposed causes. Experience has shown that calmness, cheerfulness, absence of fear, attention to the ordinary rules of health, avoidance of obvious causes of disease, the precaution not to make any sudden change in food and habits of life, and especially total abstinence from advertised or lauded specifics, are the best means of avoiding epidemic diseases or of passing lightly through their attacks. The human constitution may become acclimated to epidemic diseases in malarious climates, as is shown by the greater mortality among new comers; in the white races there is no acclimation against endemics of intermittent and bilious fevers and other marsh diseases, as the experience of our southern states and the Pontine marshes of Italy fully proves; negroes to a certain extent become insusceptible to the effluvia of the rice fields, but not so much so to the causes of disease on the cotton plantations. The smallest admixture of negro blood is a great protection against yellow fever, and a quarter mixture has been considered as perfect a safeguard as is vaccination against small pox. Negroes suffer more than whites from cholera, typhoid diseases, plague, and small pox, and are much less liable to intermittents as well as yellow fever. (See ACCLIMATION).

EPIDERMIS, or CUTICLE, the thin semi-transparent pellicle which covers the surface of the

dermis or corium. It is composed of layers of tessellated or pavement epithelium cells, of a flattened oval or polygonal shape, and about $\frac{1}{10}$ of an inch in diameter; each cell contains a nucleus with several distinct paler granules. The cells are developed from germs supplied by the basement membrane, nourished by the subjacent vessels, and cast off externally from time to time, to be succeeded by others; when first formed they are spherical, gradually becoming dry and flattened; the deeper layers are more distinctly cellular, while the outer ones are scale-like. The epidermis has no vessels nor nerves, but is pierced by the ducts of the sebaceous and sweat glands, and by the shafts of the hairs or feathers. The rete mucosum seems to be composed of the same microscopic elements as the overlying epidermis, being the principal seat of the pigment cells which give the color to the skin. The epidermis covers the whole exterior of the body, even the front of the eye, and is continuous with the epithelium of the internal mucous membrane; it is thickest in those parts most subjected to friction, as on the heel and the palms of the hands, where it becomes almost as hard as horn. Its use is to protect the sensitive true skin from mechanical injury or the contact of air; in the living body, when abraded, it is speedily replaced; but when removed by maceration or otherwise after death, the cutis underneath soon becomes brown and dry. The chemical composition of the thick epidermis of the heel has been found to be very nearly the same as that of the corneous matter of nails, hoofs, horns, and hair. The epidermis is familiarly seen in the occurrence of blisters, whether produced by friction or the application of irritating substances, constituting the raised portion under which the fluid is effused. The epidermis not only prevents evaporation from the dermis, but also prevents absorption of fluids from without; it is well known to the physician, that in introducing medicinal agents into the system by the endermic method, the process is rendered very much more rapid and effectual by previously removing the epidermis by a blister.

EPIDOTE (Gr. *ἐπιδιδωμι*, to increase), a mineral of the garnet family, being a silicate of alumina, oxide of iron, and lime. The species includes several varieties, as: 1, epidote proper, called also pistacite, or the lime and iron epidote; 2, lime epidote; 3, manganesian epidote; 4, cerium epidote. The mineral occurs crystallized, and in granular masses. Hardness 6-7; specific gravity 3.25-3.5. The colors are generally various shades of green. The finest specimens are brought from Arendal in Norway. They are also obtained at Franconia, N. H., Haddam, Conn., and at numerous localities in which crystalline rocks are found.

EPIGONI (Gr. *ἐπίγονοι*, descendants), the 7 sons of the 7 Argive heroes who, under command of Adrastus, besieged Thebes. The war of the fathers was styled that of the "Seven Against Thebes," and the sons of Adrastus were the

binned princes survived it; the war of the sons was styled that of the "Epigoni," and the only Argive hero that fell was *Ægialeus*, the son of Adrastus. In this second expedition Thebes, abandoned by its inhabitants, was razed to the ground.

EPILEPSY (Gr. *ἐπιλαμβάνω*, to seize upon). This is one of the most horrible diseases that afflict mankind, and it is not surprising that, in ignorant ages, in Rome, in Egypt, and elsewhere, epileptics were considered as having excited the ire of the Divinity, or as possessing supernatural powers, on account of which they were worshipped. This was due to the violence and extraordinary force developed by the muscles in epileptic convulsions; the screaming, the changes in color, and the contortions of the face, the biting of the tongue, followed by a comatose state and afterward by a degree of mental alienation. There are so many varieties of epilepsy that it is impossible to give a definition of the disease that will apply to them all. However, in most cases, epilepsy is characterized by convulsions and loss of consciousness, occurring at longer or shorter intervals, during which the patient is almost in good health. The absence of fever in epileptics serves to distinguish their affection from meningitis and other inflammations accompanied by convulsions. The loss of consciousness also distinguishes epilepsy from hysteria. As in most nervous diseases, a hereditary tendency is among the most frequent predisposing causes of epilepsy. Leuret and Delasiauve endeavor to show that it is very rarely inherited; but the testimony of many others leaves no doubt about the frequency of this predisposing cause. Epilepsy often appears in the offspring of persons who have had various other nervous complaints. Bouchet and Cazanvichl say that out of 180 epileptics 30 were descendants of persons who had been either epileptic, insane, paralytic, apoplectic, or hysteric. As regards the predisposing influence of sex, there is no doubt that women are much more frequently attacked by epilepsy than men. As regards the influence of age, we find by a comparison of the statistics given by several English and French authorities, that the most frequent periods of life at which epilepsy begins are early infancy and the age of puberty. Epilepsy often appears also in very old age; Delasiauve remarked that out of 285 epileptics the disease began in 10 when they were from 60 to 80 years old. In fact, there is no age that escapes. As regards climate, nothing very positive has been established, but it seems probable that the disease is more frequent in hot and in very cold than in temperate climates. Although we have no scientific data to rely upon, we think that the extreme variations of the climate of the United States are among the causes of the greater frequency of epilepsy in this country than in England, France, and Germany. Harpin, with others, states that epilepsy is more common in persons of low stature; but even if this be true, it is not a reliable criterion.

of stature a predisposing cause of the disease in many of the cases on which he holds his view it is partly the influence of epilepsy already existing in childhood or in adolescence, that has prevented the development of the body. Various malformations of the body, especially of the cranium, are certainly among the most frequent predisposing causes. Hereditary constitutions, as proved by Esquirol and by Dr. C. B. Radcliffe, are favorable to the production of epilepsy. Among other predisposing causes are dentition, the first appearance and cessation of menstruation, onanism, and the use of alcoholic drinks. Almost all kinds of diseases may produce epilepsy, but among the most important we must place those affections in which the blood becomes altered or diminished in its quantity, and organic affections of the meninges, of the cerebro-spinal axis and of certain parts of this nervous centre. Another very powerful cause, the influence of which has been demonstrated by Marshall Hall and recently by Huxley and Jenner, and by Brown-Séquard, is excessive loss of blood. Pregnancy, parturition and menstruation, frequently cause epilepsy. A tumor on a nerve, or any cause of irritation on the trunk or the terminal part of any sensitive nerve, and especially in the skin or mucous membrane, very often produces it. A burn, a wound, a burn, worms in the bowels or in the bladder, stone in the bladder or in other parts, a foreign body in the ear, &c., are all known to have caused epilepsy. It is quite certain that great mental excitement or emotion may originate epilepsy in many cases, but it is probable that the disease was not produced by these causes, but has only been brought to manifestation by this kind of excitement.—When an epileptic fit is about to take place, it is usually preceded by some sensation or some change in the condition of the patient. If a sensation precedes the fit it comes most frequently from some part of the head, and especially from that of the fingers or hands. This sensation is well known under the name of *aura epileptica*. There is as much variation regards the kind and the intensity of the sensation as there is in respect to its point of origin. Most frequently, however, the aura is a sensation of cold, of burning, or that kind of numbness produced by a draft of cold air on a particular part of the body. Sometimes the aura comes from the eye or the ear, and then a flash of light or some other sensation comes from the ear, or peculiar sounds are heard. Sometimes the patient becomes gay, others mournful, when they are about to have a fit; in others the attack is announced by some change in the digestive functions. Whether preceded or not by an attack or by any change in the functions of the viscera, a complete attack usually begins with an extreme paleness of the face, and at the same time or nearly so there are contractions of several muscles of the face, the eye, and the mouth.

Observers do not agree as regards the manifestation of a fit, probably because the disease does not always begin with the same

phenomenon. Not only have we known the first symptom not to be the same in different epileptics, but in the same one we have seen differences in this respect in 8 different attacks. Some epileptics certainly are exceptions to the rule advanced by Dr. O. J. B. Williams, which is that the first manifestation of an attack is a palpitation of the heart. Many physicians think the scream is the first symptom. It often is, but the paleness of the face usually precedes it. Some epileptics do not scream. As soon as these symptoms have appeared, a rigid tetanic or at least tonic spasm takes place in the limbs, and the patient falls. Respiration is suspended, and the face becomes quite injected with black blood, and assumes a hideous aspect both from the spasms of its muscles and the blackish or bluish hue. Sometimes a momentary relaxation is then observed in the limbs; but almost at once clonic convulsions occur everywhere in the trunk, the limbs, the face, and often in the various internal organs of the bladder, the bowels, and even in the uterus. The mouth then ejects a frothy saliva, often reddened with blood from the bitten tongue. The respiratory muscles, after the first spasms which produce the scream and suffocation, causing a gurgling or hissing sound, become relaxed, and then those employed in inspiration contract, and almost as soon as air has reached the lungs the convulsions cease or notably diminish. Ordinarily the fit is over in a few minutes; but it is not unfrequently the case that after a general relaxation another seizure comes on, and sometimes many occur with very short intermissions. During the whole time the fit lasts the patient is deprived of consciousness, and when he recovers he remembers nothing that has taken place in the mean time. In some cases the seizure is followed by a prolonged coma, ending sometimes in death. When the patient recovers from a fit, even if it has not been a very severe one, he usually feels extremely fatigued and suffers from headache. Fortunately, however, he soon falls asleep, and ordinarily is almost as well as usual when he wakes up, except that the headache and the fatigue still exist, though much diminished. When many fits have taken place, even at somewhat long intervals, such as several weeks, mental derangement often supervenes, and in this way epilepsy leads to insanity. In some cases the fits recur at regular periods; in others they return with every return of the circumstances which seem to have caused the first, such as menstruation, pregnancy, the influence of certain seasons, &c. There is seldom great regularity in the length of the interval between the fits, and they come every day, every week, every month, &c., at irregular hours. Many patients have very different intervals between their successive fits. Some have many fits a day, others one every 6 months, or every year. Delasiauve mentions a case in which the number of fits was 2,500 in a month. But the greater the number of fits the less violent they generally are.—We have already said that the

varieties of epilepsy are numerous; and among them the two principal especially require to be noticed. In a complete fit of epilepsy there are two distinct features: 1, the loss of consciousness; 2, the muscular convulsions. Each of these may exist alone. In the case of a seizure consisting only in the loss of consciousness without convulsions, we have the so called epileptic vertigo, which is a form of epilepsy that frequently exists alone, and also coexists often with the form of the disease in which the attack is complete. In this last case the patient sometimes has a complete seizure, sometimes only a more or less prolonged attack of vertigo. Whether vertigo exists alone or coexists with complete attacks, it is a very dangerous affection, not for the life of the patient, but because fits of simple vertigo lead more frequently to insanity than complete fits of epilepsy. The cases of epileptiform convulsions without loss of consciousness are not so frequent as the cases of simple vertigo. They are particularly produced by injuries to the nerves or to the spinal cord.—The nature of epilepsy, the material and dynamical conditions of the parts which are affected in the animal organism, have been greatly illustrated by the researches of modern physiologists and practitioners. Dr. Marshall Hall thought the seat of epilepsy to be chiefly in the medulla oblongata, and that its nature consisted in an increased reflex power, at least in the beginning of the disease, and also that the convulsions were the results of the asphyxia caused by the closure of the larynx (*laryngismus*). This theory is in opposition to several facts. In the first place, although laryngismus almost always exists and certainly concurs in the production of asphyxia, and in so doing generates convulsions, it cannot be considered as the cause of convulsions, as it does not always exist, and as there is one kind of convulsions (the tonic) which precedes the asphyxia. Beside, there are more powerful causes of asphyxia in the condition of circulation in the brain and the spasm of the muscles of the chest. Then, as regards the increased reflex power, Dr. Hall acknowledges that this power is diminished in persons who have been epileptic for some time. We cannot admit therefore that the disease consists in the increase of this power. Another theory has been recently proposed by Dr. Brown-Séquard. Guided by experiments on animals, in which he produces epilepsy, he has found that the reflex power is composed of two distinct powers, one of which he calls the reflex force and the other the reflex excitability. He has found that the reflex force may be very much diminished while the reflex excitability is very much increased. This last power is the power of impressibility of the cerebro-spinal axis; in epileptics this impressibility is very much augmented. The slightest excitations may produce reflex actions in them. In the beginning of epilepsy, usually the other reflex power, which is the force manifested in the reflex actions of the cerebro-spinal axis, is increased; but after

a time this force diminishes, and in most cases it becomes less, and even much less, than in healthy people. Now the nature of epilepsy seems to consist in an increase of the impressibility, or, in other words, of the reflex excitability of certain parts of the cerebro-spinal axis. In most cases of epilepsy these parts are the medulla oblongata and the neighboring parts of the encephalon and of the spinal cord. But the seat is not constant, and may be sometimes limited to the oblong medulla or extended to other parts of the cerebro-spinal axis. Dr. Brown-Séquard has tried to explain this mysterious phenomenon of loss of consciousness. It seemed very strange that at the same time that certain parts of the encephalon were acting with great energy, another part should be completely deprived of action. This, according to the above named writer, is very simple. The blood vessels of that part of the brain which is the seat of consciousness and of the mental faculties, receive nerves from the medulla oblongata and the spinal cord; these blood vessels when they are excited contract and expel the blood they normally contain, and it is known that all the functions of that part of the brain cease when they do not receive blood. Now, when the excitation that exists in the beginning of a fit acts upon the medulla oblongata and its neighborhood, it produces at the same time the contraction of the blood vessels of that part of the brain which we have mentioned, and a convulsive contraction of the muscles of the face, the eye, the neck, the larynx, &c., all parts receiving nerves from the same source as these blood vessels. In this way the loss of consciousness is explained. The following table from Dr. Brown-Séquard's work on epilepsy shows how the principal phenomena of epilepsy are generated:

CAUSES.	EFFECTS.
1. Starting of an excitation from a sensitive or an excitable part of the nervous system.	1. Contraction of the blood vessels of the brain proper and contraction of some muscles, by a reflex action from the central seat of the disease.
2. Contraction of the blood vessels of the brain proper.	2. Loss of consciousness.
3. Accumulation of blood at the base of the encephalon, due to its expulsion from the brain proper, &c.	3. Spasm of the larynx and of the muscles employed in expiration.
4. Spasm of larynx and of expiratory muscles.	4. Cry and asphyxia.
5. Asphyxia.	5. General clonic convulsions.
6. Exhaustion of nervous power, except of the part of the nervous centres employed in respiration.	6. Cessation of the convulsions and return of respiration.
7. Return of respiration.	7. Return of consciousness.

—The first thing to be done for an epileptic is to find out the cause of the disease, and to try to get rid of that cause if it still exists. Very often epilepsy depends upon some external cause of irritation which may easily be removed; it is of the greatest importance to discover if there is anywhere such an irritation, and as the patient may not be aware of its existence, it is necessary to look for it everywhere. Of the various modes of treatment, the most powerful

are those means of exciting the skin which most readily produce a change in the nutrition of the encephalon and spinal cord. All physicians know what these means are. One of the most efficacious remedies is belladonna. Physicians should not despair of curing their patients, and should not change a mode of treatment until they have given it a fair trial; and patients and their families should remember that the rules of hygiene must be followed by epileptics much more closely than by those afflicted with almost any other disease.

EPIMENIDES, a poet and hero of Cnossus, in the island of Crete, flourished in the 7th century B. C. He was a contemporary of the seven wise men of Greece, among whom he is sometimes counted in place of Periander. He was principally occupied with politics and legislation, but of his treatises on these subjects nothing remains. He also wrote a poem upon the Argonautic expedition, which is lost. There are many fabulous accounts of his life. He is said to have passed 57 years in profound sleep in a cavern, and to have possessed the marvellous power of separating himself from his body. The Athenians suffering from a plague invoked his aid, and he removed the scourge. His life was prolonged according to some to the age of 229 years.

EPINAL, a town of France, capital of the department of Vosges, and of an arrondissement of its own name, 225 m. E. S. E. from Paris; pop. of the arrondissement in 1856, 96,338, and of the town 10,140. It lies at the foot of the Vosges mountains, and is divided into two nearly equal parts by the river Moselle, along the banks of which there are fine promenades. Its fortifications are now destroyed, and it has only the ruins of its old castle. It has a college, museum, and public library of 18,000 volumes; tanneries, and manufactories of cutlery, copper, china ware, paper, and oil. Marble is quarried in the vicinity.

EPINAY, LOUISE FLORENCE PÉTRONILLE DE LA LIVE D', a French authoress, born in 1725, died April 17, 1783. She was unhappily married, and while yet young became the mistress of Jean Jacques Rousseau, with whom she lived till he became jealous of Grimm, whom he had himself introduced to her. He was also jealous of her friends Diderot and D'Holbach. She afterward maintained intimate relations with Grimm until his departure from France, when, under the guidance of Diderot, she continued his literary correspondence with the sovereigns of Europe. She wrote an educational work entitled *Conversations d'Émilie*, to which a prize was awarded by the French academy in 1783. Her "Memoirs and Correspondence" (3 vols., Paris, 1818) contains many unpublished letters of Rousseau, Diderot, and Grimm, and abounds with information on French society and character in the 18th century.

EPIPHANIUS, SAINT, a father of the church, bishop of Constantia (more anciently Salamis), in Cyprus, born in the district of Eleutherop-

olis, in Palestine, about 310, died May 12, 403. He was of Jewish parentage, but falling in with Christian teachers was baptized by the bishop Lucian, and from his youth dwelt in the deserts of Egypt among the monks, whose virtues he admired and whose mode of life he adopted. There he joined to the practices of penitence the labors of study, and mastered the Hebrew, Egyptian, Syriac, Greek, and Latin languages. At the age of 20 he returned to his native country, and founded a monastery of which he was for 30 years the superior. He wrote several books for the instruction of the numerous monks whom he had under his care. He was invited in 367 to the bishopric of Constantia or Salamis on the island of Cyprus, and in this station he became known as an able adversary of the doctrines of Arius and Apollinarius, and of many of the writings of Origen; yet it is remarkable that he was almost the only Athanasian bishop who was spared by the Arians, then in the height of their power. He visited Rome in 382, where he first met with St. Jerome. He subsequently made a journey to Jerusalem, where he had a lively contest with the Origenist patriarch John, and then repaired to Constantinople, where he took part against Chrysostom. He died at sea, while returning to Cyprus. His most important work is his *Panarium*, a discourse directed against heresies, of which he counted 80. Of all the Greek fathers he wrote in the poorest style, obscure, unpolished, and without order or collection. A standard edition of his works is that of Dionysius Petavius (2 vols. fol., Paris, 1622).

EPIPHANY (Gr. *ἐπιφάνεια*, appearance, manifestation), a festival of the Christian church, instituted to commemorate the appearance of Jesus Christ to the magi or wise men, who came from the east bringing him presents. It is celebrated on Jan. 6. It is often called the "manifestation of Christ to the Gentiles," and the Greek church terms it the theophany, or appearance of God. The eastern Christians gave it also the name of "feast of light;" in Germany it is known as the "festival of the three holy kings;" and some of the early fathers took it to be the day of our Saviour's baptism, when a voice from heaven declared: "This is my beloved Son, in whom I am well pleased."

EPIPHYTES (Gr. *ἐπι*, upon, and *φυτε*, to grow). This title has been given to those vegetable parasites which are found upon man and other animals. Those which grow within the cavities of the same are called **ENTOPHYTES**. Inasmuch, however, as no definite line can be drawn between the two, and as some species belong to both classes, they will for convenience sake be considered together in the present article. It is only within a few years, and since much attention has been given to the study of cryptogamic botany, that the full nature and importance of the diseases created by many of these growths has been recognized, and the belief in their spontaneous generation been given up. They all belong to the fungi and algae, but we

are not yet sufficiently advanced in our knowledge of cryptogamiae to attempt any minute classification, or to distinguish between these two orders. Robin and Küchenmeister, however, divide them according to their supposed place in the vegetable kingdom, while Virchow and his followers classify them into those really pathognomonic of disease, and those accidentally occurring in it. For this last arrangement the two following conditions are necessary, viz.: the constant occurrence of the parasite in the disease, and the positive result of inoculation. There are some who say that even this is not enough, and that the fungus may carry the matter of contagion attached to itself, and that this propagates the disease. Schönlein throws out such a hint with regard to animal parasites when he advises our cleaning the itch insect with brush and bath before proceeding to inoculate, and Clemens of Frankfort asks: "If we were to find constantly in the vaccine matter one and the same fungus, by the transportation of which new variola existed, which should we call the true inoculating matter, the fungus attached to the lymph, or the lymph attached to the spores?" The dwelling places of the cryptogamiae seem as universal as their growth is simple. Deep under the sea are lying beds of algæ; within the bowels of the earth they may be found; the air we breathe contains them, and the winds waft them from pole to pole. They form the chief means of resolving dead matter into its original elements, and are present and are gone with a rapidity alike inconceivable. No wonder that men believed in the spontaneous development of these forms, for their appearance in certain situations seems otherwise inexplicable. The animal parasites live mostly on the living tissues of man; with the vegetable the reverse is generally the case, and it is those parts already decomposed or diseased which form their chief support. They usually attack, or better succeed in establishing themselves upon, parts not intimately connected with the system and superficial, and therefore less able to resist their influence; or else they attend upon long disease, when the strength of the body is already wasted. This cannot be said, however, of every species. The character of the soil exercises an important influence over their growth, and may in fact change it entirely. Indeed, we can hardly give any general rules; for some affect an acid nutriment, others alkaline; some grow upon the outside, where there can be no warmth, others within the heated cavities of the body; some thrive best in light and pure air, others in darkness and carbonic acid; some live in fluid, while others are always found dry. It will be seen then that all these points must be taken into consideration before we attempt to destroy them, and a universal parasite killer is an impossibility, for what is death to one species may be the food of another. The effect of their presence on man is as various as that of the animal parasites, though less dangerous. When the plant has found its favorite and

essential elements for reproduction, it grows at once, be it on the outer surface or within the body. At first the growth may be merely superficial; but soon the vegetative process, the mycelium, begins to seek nourishment in deeper soil, and its filaments penetrate all tissues, wherever the minutest hole is left for its entrance. The spores or mycelium may, by acting as a foreign body, produce absorption in adjacent parts, and thus make way for their progress inward indefinitely. When once the spores gain admission we may see the same result as when we plant the seeds of larger vegetables in the soil. They send forth their sprouts upward and downward, pushing before them whatever resists their progress. But if in addition to the sprouts we should have our seed increasing by self-division, and to an immense extent, what would follow? What wonder then if this process, carried on beneath the less yielding skin, should lead to inflammation and destruction of the parts? The *oidium albicans* may produce death in an infant by stopping the œsophagus or wind-pipe. Impaired vision may be caused by the growth of a fungus within the eye. Atrophy and deformity may result from their presence in the hair and nails. Erosions of the skin, and the inflammation they create, may bring on swelling of glands. Parasites may also prove injurious by irritating the nervous system, as in *pityriasis versicolor*, or chemically. The vinous fermentation is brought about by the action of a fungus on sugar, by which it is resolved into carbonic acid and alcohol. Now saliva changes the starchy compounds of food into sugar, and the presence of a fungus may convert this in turn into alcohol. So too the *sarcina ventriculi* and the *oidium albicans* may cause the acetous and lactic acid fermentations respectively. The very decay of vegetable parasites may produce putridity in their masses. There is not the slightest ground, however, to believe the presence of fungoid growths in the body or atmosphere has aught to do with the spread or cause of epidemics. We see then that vegetable parasites are able to work a multitude of evils upon mankind, but the extent thereof must be in proportion to the condition and size of the organ affected. Although they may in some instances be as troublesome, as dangerous to life even, as their animal relatives, still we are not so much shocked to have our head covered with the sporules of the favus plant as with pediculi, though both are marks of uncleanness, or to know that our stomach is filled with *sarcina*, as to suspect that a frightful *strongylus* lies coiled up in our kidney. Before discussing the various species, it will be well to describe in a few words the nature and growth of fungi, referring for further information to the article on FUNGI. They consist of organs of fructification, and a nutritive apparatus. This last is called mycelium, and is made up of threadlike, more or less compacted, elongated cells, which interlace and have no intimate connection. It has such an indefinite form, and differs so little

when we consider their customs—the nipple taken from one child and given to another, feeding various children with the same spoon, and so on. How it appears in sporadic cases also is not difficult to explain, believing as we do that it is an ordinary form, which may grow on many substances, and be transported in the form of its sporules in all directions by the air.—Nothing more than a sketch can be given of the various diseases caused by these parasites, and their treatment must be entirely omitted. For convenience sake they may be divided into the 3 following groups: those of the alimentary canal, of the scalp, and of the skin. In the first we place the *oidium albicans* already described, and here too belongs the *torula cerevisiæ*, or yeast plant, its near relative, which is met with occasionally in all the fluid excretions of the body. It forms the ordinary cholera fungus in the vomitus and intestinal discharges of this disease, and is often found in the stomach and attached to the walls of the intestine after death. Its usual presence in fermenting fluids has led to the belief that it was the cause of such change, and we know that when added as yeast it acts as a true ferment; but we do not know but that the peculiar chemical change may offer merely the conditions for its sudden appearance and rapid growth. It is another form of the *penicilium glaucum*. Another plant, found most commonly in the fluid of the stomach, is the *merismopadia* (or *sarcina*) *ventriculi*, which has been usually placed among the algæ. It has been found also in the urine, in the intestinal canal, and in the lungs. Its presence in the stomach of man probably causes no symptoms whatever; and Hasse's pretended dyspepsia attributed to this parasite is without any foundation, for it has been cultivated in the stomach of rabbits, and no trouble caused by its presence. It is supposed to be present most frequently in patients suffering from some gastric disease, organic or otherwise, but this is to be accounted for by the fact that such only vomit, and afford material or stimulus for investigation. If we remove from our teeth the yellowish white deposit which collects after the neglect of the tooth brush for several hours, we shall find by microscopic examination, in addition to the detritus of food, a cryptogamic plant called *leptothrix buccalis*. It is to be found in all persons, however cleanly they be, and forms a large part of the tartar which collects about the teeth. It grows with great rapidity after eating sugar, and has been seen in the stomach. Of the parasites of the scalp, the *achorion Schönleini* is most of all to be dreaded, on account of the deformity and disagreeable odor it gives rise to. It produces the disease known as *favus*, *porrigo farosa*, or *tinea lupinosa*. The spores first settle upon the epidermis of the head, and send forth the mycelium, which penetrates the hair follicles and finally the whole course of the hair itself. The hair becomes pale and lustreless, breaks easily, and is surrounded at its base by concentrically

marked yellow and roundish crusts, which smell vilely, and consist of spores and mycelium. From one point this fungus may spread over the whole scalp, producing baldness and scars. Fortunately it is of rare occurrence, for a cure is almost impossible. The *trichophyton tonsurans* and *T. sporuloides* also cause baldness when they attack the hair, and the former produces the disease called ringworm which is so prevalent in asylums for children. The *microsporon Audouini* likewise attacks the hair, and the *M. mentagrophytes* the beard. The only vegetable parasite which is found upon the skin alone is the *M. furfur*, which is the cause of the eruption which is known as *pityriasis versicolor*. Several of the above-mentioned species may take root upon the skin as well as the scalp, but they never form a well marked disease like the latter. Various kinds of cryptogamiæ have been observed in other situations, as within the ear, eye, lungs, and nails, but the descriptions of them are very defective, and we hardly know where they belong. It is probable, however, that they are species of fungi which have accidentally found a favorable place for development.—Man, however, is not the only animal infested by the vegetable parasites. Upon the mammalia it is true that few have been observed, but this remains an almost unexplored field to future investigators. Many birds bear them in their respiratory apparatus, especially the owls, which inhabit damp and shady retreats, frequented by fungi. More curious is it to find within the close-shut cavity of an egg mycelium spreading throughout the contents, and changing them by a peculiar chemical action. Here the upholders of the theory of spontaneous generation thought to have demonstrative proof of the justice of their views. The phenomenon, a rare one, is produced by the admission of spores within the oviduct before the egg shell is formed. Fish are often taken covered with vegetable growths, which impede their motion through the water as the barnacles act upon ships. A great many species have also been described which are found only upon their gills and in the cellular tissue. In an aquarium, whenever an injury happens to any of its inhabitants, the wounded surface is seen at once to be covered with fungoid growths, which often attain a large size. But it is the insect tribe which suffers most from this cause; for their diminutive size is little able to cope with the parasite, which when once fastened increases at their expense, till it exceeds them in size and destroys them. Flies may be seen at certain seasons struggling through the air with long stems attached, the mycelium of which spreading inward stops their breathing tubes. Certain species of *sphæriæ* grow within the larvæ of insects in China and Australia, and completely mummify them, so that they resemble twigs of wood, from which sprout forth branches. The most important of all, however, in an economic point of view, is the *botrytis bassiana*, which is so destructive to the silkworm. This

and authority in part at least of a poor character, were unknown, and by many held to be impossible. It is also affirmed specially in New England, a fear that if the political dependency of our country on the mother of England should be much longer permitted, the establishment of an episcopate at home in England would be inevitable, and much to the zeal which characterized the struggle for American independence. In the state of things, as was natural, when the church was actually broken out, some of the churchmen in the northern states, and more especially those of the northern states, were opposed to it, and were called tories; while others, and especially those in the southern states, heartily supported the cause. Washington himself was a son of England man before the revolution, and after the treaty of peace he remained and continued in the communion of the Protestant Episcopal church. Mr. Duché, the first chaplain to the army, was a church of England clergyman; Bishop White of Pennsylvania, the first American bishop, was from the first an ardent supporter of American independence. As early as 1782, a plan had been proposed for a union of the church of England with the American church into an independent branch of the church in America. No organization, however, was completed until Sept. 1785; but before this the Episcopalians of Connecticut elected the Rev. Samuel Johnson, D.D., to be their bishop. Dr. Seabury, in consequence of some political obstacles to his return to England, went to Scotland and was consecrated, Nov. 14, 1784, by three Scottish bishops, Robert Kilgour, Arthur Petrie, and John Skinner, at Aberdeen. The general convention, however, which met in 1785, made no provision for the English church for the consecration of more bishops of the American church. In 1786 Dr. William White of Pennsylvania and Dr. Samuel Provoost of New York were designated and elected, each respectively to the parishes in the states to which they belonged. They were consecrated in the White Palace chapel, Feb. 4, 1787, and on Feb. 19, 1790, James Madison of Virginia was consecrated in like manner for the American church in Virginia. In 1789 the general convention met, consisting of the then bishops (although Provoost took little or no part in its doings), and clerical and lay members from each of the states in which any Episcopal organization had been effected. At this meeting a constitution and laws for the organization and government of the church as a national branch of the catholic church of Christ were adopted. The English prayer book, revised and adapted to the altered political circumstances of the country, was set forth to be read in all the congregations after Oct. 1, 1789, and it remains unchanged to the present time. In the alterations thus made in the English formularies, it is declared that "this church does not intend to depart from the church of England in any essential point of doctrine,

discipline, or worship, or further than local circumstances require." And it has been held that in consequence of this declaration in the preface to the American prayer book, as well as on general principles, the Protestant Episcopal church in the United States retains all the common and canon law of the English church, except in so far as "it may have been deemed inapplicable by its local circumstances," referred to in the preface, or modified or repealed by express legislation. The Protestant Episcopal church in the United States retains from the church of England the Apostles' and Nicene creeds, the XXXIX. articles, with a slight modification in reference to the connection of the civil government with the church, and the catechism and baptismal offices. But for the communion office it has rather followed the Scotch than the English church in placing a prayer of consecration and invocation of the Holy Ghost upon the consecrated elements before the administration of them to the communicants, and has even added to the Scotch service a few words making still more unambiguous the eucharistical character of the sacrament. The American church has also stricken out from its form for visiting the sick the formula for private absolution; and in the exhortation preceding the administration of the holy communion, it has omitted the direct reference to and advice in favor of private confession to the priest, and absolution from him. In this revision of the offices, Bishops Seabury and White were chiefly instrumental as the guiding minds, and Bishop White has left behind his testimony to the harmony and agreement of views and feelings with which they coöperated in the performance of this task. In the offices of institution, established in 1804 and set forth with alterations in 1808, the word "sacerdotal" is introduced as describing the functions of the Christian ministry. This is regarded as significant and giving definitiveness to the view taken of the nature and offices of the Christian ministry in this branch of the church. The theory of the Protestant Episcopal church, like that of the English church, is that in order to be a valid branch of the church of Christ it must have the Holy Scriptures and the ancient catholic creeds, the ministry in an unbroken line of succession from the apostles, and in the exercise of lawful jurisdiction; and that the Christians of any nation with these conditions constitute a national branch of the church of Christ, totally independent of the jurisdiction and authority of any foreign church or bishop, subject only under Christ to the authority of the universal church in general council assembled; and that as such they have jurisdiction over all their members and authority in matters of faith to interpret and decide, and in matters of worship and discipline to legislate and ordain such rites and ceremonies as may seem most conducive to edification and godliness, provided they be not contrary to the Holy Scriptures. The Scriptures and the creeds, as already said, the Prot-

Episcopus was the theologian who first developed its ideas with skill. Beside his many controversial pieces, the most important of his writings is the *Institutiones Theologiæ*. A collection of his works was published by Courcelles (2 vols. fol., Amsterdam, 1650).

EPISTOLÆ OBSCURORUM VIRORUM (letters of obscure men, the word *obscuri* being intended to mean at the same time ignorant and illiberal persons), a collection of satirical letters in dog Latin, published anonymously in 1515 and 1517, the first part at Hagenau, by the learned publisher Angst, the second at Basel by Froben, though Venice is named on the title page as the place of publication. These letters are conspicuous in the history of the reformation in Germany. At that time John Pfefferkorn, a converted Jew, and Jacob Hoogstraaten, were foremost among those in Cologne who endeavored to keep down the light of independent thought developed by the study of the classics. A violent literary feud between them and the liberal thinkers, Reuchlin especially, caused the publication of the *Epistolæ*, a keen and caustic satire on the ignorance and perversity of the clergy at that time. There was much uncertainty in regard to their authorship. Reuchlin, Erasmus, and Ulric von Hutten were severally supposed to have been the authors. But careful investigation has shown that there was a large number of contributors, including Ulric von Hutten, Herman van den Busche, E. Hess, Peter Eberbach, Rhegius, Sommerfeld, Cæsarius, Pirkheimer, Wolfgang Angst, and Jacob Fuchs, for the first volume, and beside them, Herman van Nuevar and F. Fischer for the second. The *Epistolæ* were prohibited by the pope in 1517, in consequence of which their popularity increased. The book has been frequently republished. The best editions are those of Frankfort (1643), London in 12mo (no year given), that edited by Maittaire at London (1710), a new edition by Rotermund (Hamburg, 1827), another by Münch (Leipsic, 1827), and the latest by G. Böcking (Leipsic, 1859). The latter includes also a 3d volume, published for the first time in 1689. The satirical form of the *Epistolæ* has on several occasions been imitated by more modern authors. One of these imitations is *Epistolæ Novæ Obscurorum Virorum*, published by Prof. Schwetschke, at Halle (1849), as a satire on the German parliament.

EPITHELIUM (Gr. *ἐπι*, upon, and *θηλή*, a nipple), the layer of cells lining the internal free surfaces of the body, continuous with the epidermis which covers the external surface of the skin. It arises from cells like the epidermis, which are developed and thrown off in the same manner in both structures; the epithelium, however, serves for totally distinct purposes in the animal economy, as from the soft and moist surfaces covered by its cells are elaborated the various secretions of the body. A continuous layer of its cells may be traced the whole length of the alimentary canal, along the other mucous membranes into the

glands and follicles, on the serous and synovial membranes and the coats of the blood vessels and absorbents. The two principal among the numerous forms of epithelial cells are the tessellated or pavement epithelium, and the cylindrical epithelium. The tessellated epithelium lines the serous and synovial membranes, the blood vessels, the follicles of most of the cutaneous and mucous glands, and many parts of the mucous membranes; the cells are generally flattened and polygonal, forming by their contact a kind of pavement, and the number of layers is usually small. The cylinder epithelium covers the mucous membrane of the alimentary canal, the larger ducts of the glands, the vas deferens, and the urethra; its cells are cylinders, arranged side by side, one end resting on the basement membrane, the other forming the free surface. These two kinds pass into each other at various points, giving rise to various transition forms, and both are often fringed with delicate filaments or cilia, varying in length from $\frac{1}{3.000}$ to $\frac{1}{3.000}$ of an inch. (See *CILIA*). Ciliated epithelium is found in the cerebral cavities, the ramifications of the bronchi, the air passages, with their nasal, frontal, maxillary, and lachrymal appendages, the posterior faucet, and Eustachian tube; their function seems to be to expel the secretions of these various membranes. The epithelial like the epidermic cells are in a state of continual separation and renewal, more rapid according to the activity of the connected function; the introduction of nutrient matters, the separation of effete substances, the various products of secretion, and the development of the reproductive particles, are effected by the agency of epithelium cells.

EPIZOA (Gr. *ἐπι*, upon, and *ζωον*, an animal). This term as used by Owen signifies only a singular class of humbly organized articulate animals, which infest the skin, gills, and eyes of marine animals. We shall give it, however, a much more comprehensive meaning, and describe under it the most important of the external parasites of the animal kingdom. They all belong to the order *articulata*, and to the classes *crustacea*, *arachnida*, and *insecta*. Beginning with the first of these divisions, we shall find that, like the entozoa, many of them possess limited powers of locomotion, and consequently must pass the whole term of their existence upon the animals they infest; but that as we ascend in the scale of organization, and come to the arachnida, and especially the insecta, there is no longer this dependence upon a fixed position for sustenance and habitation, and that, more independent of the will of others, they only make use of their hosts for accidental nourishment, or compel them to take charge of their young while in a helpless condition. We shall consider the most important of them in the order of this classification, referring for their anatomy and general description to the articles respectively devoted to these classes. I. *Crustacea*. The parasitic representatives of this class are confined to the pœcilopodous entomostraca, and

the sebaceous matter is rendered clear. In the dead body they will be found much more deeply seated, as if they had sought warmth by penetrating toward the centre as the periphery became cold. The *acarus*, or *sarcoptes scabiei*, or itch insect, will be fully considered in the article Itch, and may therefore be passed by without further notice here. Still other forms of *acari* or *sarcoptes* are sometimes met with on man, transferred to him from the beasts on which they live. Their occurrence, however, is purely accidental, and they are never known to reproduce in such situations. The eruption they cause may, it is true, be of long continuance, but only because fresh infection takes place by continued contact with the animals affected. The *sarcoptes* of the various domestic quadrupeds produce upon them the disease known as mange, and are specifically different. The mite of the cat and lion, however, resembles and is probably identical with that of man; so that it is a question whether these lower creatures got their itch first from their noble master man, or *vice versa*. The parasite of the horse is large enough to be visible to the naked eye, and its mode of burrowing and of reproduction is nearly the same as that of the *sarcoptes hominis*. It produces a dry scaly appearance of the skin, which is sometimes called "scratches." The cheese and dried-fruit mites may likewise live for a short time on the skin, but cause nothing more than a passing irritation. The family of *ixodes*, or ticks, is also a great plague to man and beast. They live on moss and dry foliage, on sunny hillsides, and in groves and thickets, and never fail to attack grazing cattle and passers by. They bore into the skin with their sharp proboscis armed with horny barbs, and remain hanging till the body, at first minute and flat, becomes swollen with blood, even to the size of a bean. To tear them away is impossible on account of their recurved barbs, and great caution and patience is necessary; for if violence is used, the head remains behind, and causes inflammation of the part, which may last for months. Generally long and gentle rubbing with some essential oil will make them quit their hold voluntarily. They lay a vast number of eggs, and their multiplication upon oxen and horses is sometimes so great that the animals die of exhaustion. The *gamasida*, beetle lice, are other mites parasitic on birds, reptiles, and insects, and both land and water beetles are sometimes found covered with them. The *dermanysus arius* abounds in great quantities in bird cages and hen houses, and lives upon the blood of their inhabitants. Numerous cases are on record of their presence in great numbers on persons who frequent such localities, penetrating and living beneath the epidermis. They produce the disease occasionally met with among the wretched and filthy sick of the poor, called *acariasis*. Colonies of mice are often infested with similar parasites. Another mite similar to the *ixodes* is the *leptus autumnalis* of Europe, which, living in grass or grain or

upon fruit bushes, gets upon the reapers and passers by, and causes pustules and sores by the inflammation it excites. It is of a red color, whence the name of the disease, *rouget*. A similar parasite is the *bête rouge* of Martinique, which often renders necessary amputation of the soldier's limbs it infests. III. *Insecta*. In discussing this division, we shall consider the parasitic insects of animals in order, beginning with those of the mammalia. The human body serves as a residence for several of these, the best known and most numerous of which are the *pediculidæ*, or lice, which belong to the apterous *ametabola*, or wingless insects without metamorphosis. Of these, 4 are peculiar to man: *P. capitis*, *P. vestimenti*, *P. tabescentium*, and *phthirius pubis* or *inguinalis*. The color of the head louse is a grayish white, and it is supposed to adapt itself to the color of the hair of its host. The males are smaller and less numerous than the females. The eggs, which are bean-shaped, cling to the hair as soon as laid, probably by means of some glutinous matter secreted by the female. After remaining as nits for 6 days, the young emerge, and at the end of 18 days more are capable of reproducing. Each female can deposit 50 eggs in all. The presence of lice is easily detected, for we may see them with the naked eye, and their eggs attached to the ends of the hair cannot escape detection. Even when the old are at work beneath the disgusting disease they create, the females creep forth to deposit the nits upon the fine ends of the hair, perhaps because too great heat is prejudicial. A mere itching is the first symptom of lice, which leads in simple cases to scratching and slight excoriations of the scalp. Let heads so infested, however, remain for months uncombed and uncared for, and such cases will result as are often seen in European hospitals. A specimen is brought in with hair all matted together in flakes, and looking as if sand and molasses had been poured upon it and dried. The stench emitted is loathsome and sickening. On raising the hair a frightful mass of filth, pus, scabs, and lice is visible. The scalp is found covered with crusts of blood, with open ulcerating sores, and with thick and elevated scabs, from beneath which on pressure pus flows freely. The ears, too, may be converted into a suppurating surface. The *P. vestimenti*, or body louse, is much larger than the preceding species. The head is longer, and its color dirty white. This animal is seldom if ever found on the body, but inhabits the seams and folds of clothing next the skin, where it deposits its eggs. Its bite causes the same itching as that of the *P. capitis*, but the results are different. The scratching brings on papules, which become excoriated, and eczema appears. The clothes adhere to the skin, which brings on exudation, and lastly pustules appear. In some cases constant scratching produces such a hyperæmia, that a deposition of pigment follows sufficient to color the whole skin like that of the negro. The *P. tabescentium* of writers

has longer antennæ and a larger and more distinctly separated thorax than the two preceding species, and an indistinctly ringed abdomen. It inhabits the skin itself, living in its fold beneath the epidermis, and produces the disease called *phthiriasis*. Leenwenhoeek overcame his nature to such an extent as to cultivate a colony on his own leg for a considerable time, and by estimation found that one female might in 8 weeks become the grandmother of 5,000. It is proper to state, however, that some of the best authorities deny the existence of any such species. The *phthirus pubis* is considerably broader, and has a shorter posterior extremity than its relatives. Its legs are long, and the hindmost two are armed with immense claws. It is very slow in its motions, and has no eyes. This species, as its name implies, is found most frequently on the pubes, but occasionally on the beard, eyebrows, and hair of the breast and axillæ, where it bites deeply into the skin, and lives upon the blood of its host. When present in numbers, these parasites cause an intolerable itching, and may be seen sticking firmly to the surface of the body like black specks of coal. Küchenmeister has found on the heads of an Egyptian mummy and a New Zealand savage nits, the claws of which differ somewhat in size from those of the ordinary species. Lice are a world-wide pest, and no nation seems free from them. According to Aristotle, they must have been a great plague among the ancients, and Aleman, Sylla, and Philip II. are reported to have died of them. It is probable, however, that some other parasite, as the mites, was confounded with them.—Rising a step higher among the insects, we come to the *hemimetabola*, or those with an incomplete metamorphosis. In the order *hemiptera* we find the *cimex lectularius* or *acanthia lectularia*. The bedbug has a small head, from which project 2 long 3-jointed antennæ. Behind the compound eyes are situated 2 small transparent flaps covered with bristles, which are the rudiments of wings. The thorax is broad and short, the abdominal segment very large, broad, and flat. The eggs are long and cylindrical, and are furnished with a stem, by which in the spring the female fixes them upon objects. It is of a reddish brown color, and has a very disagreeable odor, which arises from two glands that contain a red and granular matter. This pest inhabits the crevices of beds, walls, and furniture, or wherever it can find a convenient place to conceal itself by day. It will lodge in garments also, but always emerges at night to prey upon the blood of man. Its predatory excursions, however, are not wholly confined to the night, for when present in the clothing they bite as well by day. The skin of some individuals seems quite insensible to their sting, while upon others it causes great local irritation. The black point seen in the centre of the spot is caused by the coagulation of the blood left in the wound. Sometimes a person is literally almost devoured by these

creatures, and the whole body may be covered with the eruption they produce. They are found generally wherever man exists, though not in South America, New Holland, or Polynesia.—The flea (*pulex irritans*) belongs to the holometabolous *aphaniptera*, or hopping *diptera*, which undergo a complete metamorphosis. Its head is short and rounded. The eye is simple. The mouth is provided with two 4-jointed parts with a long tongue protected above by a short double upper jaw, and a sort of upper double lip or taster, and below by a projecting under jaw. The thorax is provided with 2 pairs of stigmata, and with 3 pairs of legs, the first of which are seemingly situated on the head. The 2 hindmost are composed of many small joints, which are very long, and furnish the means by which its enormous leaps are taken. They are provided also with long double claws. The posterior segment is covered with 10 plates or rings lapping over each other, as shingles on a roof. The color of this parasite is a reddish brown. The male is smaller than the other sex, and the abdomen is flatter and broader. The eggs are oval, white, and covered with a glutinous matter. In 6 days after their deposition, either in dust or beneath the nails, small worm-like, jointed larvæ without feet creep forth from them. In 11 days more they envelope themselves in a thin cocoon, from which at the expiration of 11 days they emerge perfect animals. It is a disputed point whether the males are parasitic; Küchenmeister argues from the structure of their head that they are not. Little need be said here about the customs of this insect, which in some countries, as Italy, Turkey, and Germany, is such an intolerable nuisance. It bites all the time, day and night, and is never satisfied. Its bite, though productive of more itching, does not cause the great irritation the *acanthia* produces. Their horny covering or mail protects them from being crushed except by a wonderful degree of pressure, and their alert senses enable them to avoid the hunter's hand, unless it be a skilled and experienced one. The *pulex penetrans*, or chigo, jigger, or sand flea, as it is variously called, is smaller than its relative, and has a proboscis longer than its body. It is found only in the West Indies and tropical regions of South America. It inhabits the sand and chinks in the stalls of animals, and it is only the impregnated female that is found on man. She bores deeply into the skin in order to deposit her eggs, and as soon as an attachment is obtained her hindmost segment swells up in a wonderful manner beneath the skin, so that the thorax and head appear as appendages to a bladder of the size of a pea at times. This sac contains the eggs or larvæ, which, if the sac is broken during removal, are scattered through the tissues, and give rise to troublesome ulcers, which may at times necessitate amputation. Its presence causes much pain, and its removal uninjured may be effected simply with a needle, as soon as the swelling takes place.—We have

still to mention several forms of insects, the larvæ of which are occasionally found either in or on some part of man, but they are to be looked upon more as an accidental occurrence, and as such need only be alluded to here. The larvæ of some unknown *æstrus* are sometimes met with beneath the skin. They form pimples from which flows a moisture, while around them the skin is red and painful. Humboldt met in his South American travels Indians with large parts of their exposed bodies thus affected. In the intestinal canal the larvæ of *anthomyia scalaris* and *canicularis* are sometimes found. The *musca vomitoria*, or bluebottle, sometimes deposits its larvæ in open cavities of the body, as the ear, eye, or wherever else moisture and heat are found. The common flesh fly, *M. canaria*, and the *M. domestica*, also deposit their eggs at times in hot weather either on open wounds or moist places of the body, and cause the appearance known as "live sores." The larvæ are sometimes deposited in a highly developed condition, so that they become maggots even in a few hours. Quadrupeds also are infested by lice, almost without exception each by one peculiar to itself, though sometimes one species is known to live upon several animals of the same genus. They increase with great rapidity upon such beasts as are kept in dirty stables, seldom cleaned, and poorly cared for, and most frequently are seen upon old horses. They cause irritation, roughness of skin, and loss of hair, in consequence of the disposition of their hosts to bite and rub the affected parts. Fleas too abound upon several animals, and are distinct species in most instances. But the most frequent and troublesome pests of the herbivora are various *æstri* or breeze flies. The *æstrus* peculiar to the horse, for instance, produces the well-known disease called bots. (See Bots.) Another species, *Æ. ovis*, deposits its eggs in the nostrils of sheep, usually about half a dozen in each individual. The larvæ are soon hatched, and creep by means of their 2 anterior hooks upward into the frontal and maxillary sinuses. There they remain until ready to undergo metamorphosis, when they fall out, gain their wings, and repeat the same process. The larvæ are composed of 12 segments beside the head. Sheep fear these flies greatly, and often huddle together with their heads close to the ground to avoid them. The symptoms of their presence are sneezing and a discharge of glairy mucus from the nostrils, but they seldom do serious injury. The *Æ. bovis* lays its eggs on the backs and sides of oxen and cows. The larvæ, hatched by the heat, penetrate the skin, and by increase of size form tumors as large as pigeon's eggs. They live upon the pus their presence produces. After a time they make a larger aperture, and, creeping out, seek a proper place in which to become chrysales. The fly when discovered creates a great panic among cattle, and drives them often frantic to the nearest pool. Birds, too, are nearly all infested by lice, each species generally

supporting its own species of parasite, and sometimes more, which lives upon the feathers and blood of its host. Insects also, fortunately, are made a dwelling place by other insects, and thus their rapid growth and the consequent destruction of vegetation held in check. Ichneumon is the name given to these unnatural parasites. They are small flies with slender bodies, and there are many species known, probably as many as there are of caterpillars and moths. The female deposits her eggs in the larvæ, pupæ, or eggs of other insects and spiders. When she has found her proper host, a caterpillar for instance, she seizes it, and deposits her egg in the skin behind the head. The larva, soon emerging from the egg, eats its way along within the caterpillar, avoiding those parts essential to life, and by the time the latter has become a chrysalis the former is nearly mature. It lies quiet for a time to undergo metamorphosis, and awaking once again a perfect animal, bores its way out from the cocoon of its murdered host, and flies forth in quest of fresh victims. Thus it is that nature keeps in check its most destructive creatures by means so insignificant and unseen.—For fuller information on the crustacean epizoa, see Roussel de Vauzème, *Sur le cyamus ceti*, in the *Annales des sciences naturelles* (Paris, 1834); Burmeister, *Beschreibung einiger neuen oder weniger bekannten Schmarotzerkrebse*, in the *Novæ Actiones Naturæ Curiosorum*, vol. xix. (Berlin, 1835); Köllar, *Beiträge zur Kenntniss der lernäenartigen Crustaceen*, in the *Annalen des Wiener Museums der Naturgeschichte*, vol. i. (1835); Dana and Pickering, "Description of the *Caligus Americanus*," in the "American Journal of Science," vol. xxxi., p. 235; Baird, "British Entomostraca" (Ray society, London, 1850).—For arachnida and insecta, see Bracy Clark, "Observations on the Genus *Æstrus*," in the "Transactions of the Linnæan Society," vol. iii. (London, 1797); Treviranus, *Ueber den Bau des Nigua*, in his *Zeitschrift für Physiologie*, vol. iv. (1831); Brant and Katzeburg, *Medicinische Zoologie* (1833); Dugès, *Recherches sur l'ordre des acarïens*, in the *Annales des sciences naturelles*, vol. i. (Paris, 1834); Burmeister, "Manual of Entomology," translated by Shuckard (London, 1836), and *Genera Insectorum* (Berlin, 1833-'46); Newman, "History of Insects" (London, 1839); Westwood on "Insects" (2 vols., London, 1839), and bibliography therein contained; Denny, *Monographia Anoplurorum Britanniae* (London, 1842); Dujardin's *Mémoires sur les acarïens*, in the *Annales des sciences naturelles*, vol. iii. (1845); Siebold, "Anatomy of Invertebrata," translated by Burnett (Boston, 1854); Wedl's *Grundzüge der pathologischen Anatomie* (Vienna, 1854); Küchenmeister, "Manual of Parasites," translated by the Sydenham society (London, 1857).

EPOCH (Gr. *εποχή*, a fixed point, an epoch), a starting point or era from which to date. (See CHRONOLOGY.)

EPROUVETTE, an instrument for testing

the projectile force of gunpowder. It consists of a small barrel of great strength, in which a certain quantity of powder is exploded, and the force exerted is measured by the extension it produces upon a spring, or the distance to which a heavy weight is raised. The effect is also estimated by the distance to which a ball of known weight is thrown from a small mortar by a certain quantity of powder. The French formerly used a mortar for an eprouvette of 7 inches calibre, and the test of the powder was for 3 ounces to throw a copper globe weighing 60 lbs. to the distance of 300 feet.

EPSOM (Sax. *Ebbsham*), a market town of Surrey, England, on the margin of Banstead downs, 15 m. S. W. of London, on the London, Croydon, and Epsom railway; pop. in 1851, 3,390. At one time it seemed destined to become a prominent watering place, in consequence of the discovery of medicinal springs, impregnated with sulphate of magnesia, from which the celebrated Epsom salt was manufactured. The springs are no longer visited, but the town has gained another attraction in the great annual races held during the week preceding Whitsuntide on the neighboring downs. They are attended by 300,000 or 400,000 persons of every class of society, and the grand stand on the race course, erected in 1829-'30, is capable of holding 7,500 persons. The chief excitement centres in the race for the Derby stakes, which takes place on Wednesday.

EPSOM SALT, the name given in pharmacy to the hydrated sulphate of magnesia, which was obtained as far back as the year 1675, by evaporating the waters of some mineral springs at Epsom. Sea water was afterward found to contain it, the brine remaining after the separation of the common salt consisting of the sulphate of magnesia and the chlorides of magnesium and calcium. It was readily obtained by collecting the first crystals which formed, and washing them with a strong solution of the same salt. An excellent quality is manufactured at Baltimore and Philadelphia, from the mineral magnesite, a silicious hydrate of magnesia, which is found in the serpentine of that region. The mineral, reduced to powder, is dissolved in sulphuric acid. The product being dried is calcined in order to decompose the sulphate of iron, and convert it into the peroxide of iron. It is then dissolved in water, and any iron present is precipitated by sulphuret of lime. The crystals of sulphate of magnesia are separated and dissolved again to complete their purification. This salt, and calcined magnesia also, have been prepared from the dolomite or magnesian carbonate of lime, by the process of Mr. William Henry of Manchester. The mineral was calcined, and the lime and magnesia were then converted into hydrates by sprinkling with water; the former was dissolved out by a minimum quantity of hydrochloric acid, and the latter was converted into a sulphate by sulphuric acid.—Epsom salt is also found as a mineral substance, incrust-

ing the walls of caves, in the form of an efflorescence, and also in silky fibres. In the Mammoth cave in Kentucky, loose masses of it are seen adhering to the roof like snow balls, and in many other caves of the western states it is found upon the walls or mixed with the earth upon the floor. It occurs in some of the gypsum quarries near Paris, and in other parts of France; and wherever water becomes charged with gypsum or sulphate of lime, and flows over rocks containing carbonate of magnesia, the sulphate of magnesia is likely to appear from the result of mutual decomposition of the two salts. Hydrated sulphate of magnesia consists of 1 equivalent of magnesia, 20; 1 of sulphuric acid, 40; and 7 of water, 63=123; or, per cent., magnesia 16.26, acid 35.52, and water 51.22. It crystallizes in 4-sided prisms with reversed dihedral summits, or 4-sided pyramids. Their hardness is 2.25, and specific gravity 1.75. The crystals effloresce slightly in the air, and if they contain any chloride of magnesium this is shown in their deliquescing. They dissolve in their own weight of water at 60°, and in $\frac{1}{4}$ their weight of boiling water. Sulphate of soda is sometimes fraudulently mixed with Epsom salt. Its presence may be detected by dissolving 100 grains in water, and precipitating with a boiling solution of carbonate of potash. Unless this precipitate of carbonate of magnesia amount when dried to 34 grains, sulphate of soda is no doubt present. The salt is much used in medicine as a cathartic, and being of a mild and cooling nature, is particularly adapted to the treatment of fevers and inflammatory affections. The medium dose is an ounce, and this is said to be deprived of its bitter taste, and rendered quite palatable, by being dissolved in about a pint of water, and boiled a few minutes with $1\frac{1}{2}$ grains of tannic acid or 2 or 3 drachms of roasted coffee, strained, and sweetened with sugar.

EQUATION (Lat. *æquo*, to make equal), an algebraic sentence affirming the equality of two quantities. Equations, however, are used not only in simple algebra, but in all the higher branches of calculus, according to the general principles explained in the article ALGEBRA.—EQUATION OF PAYMENTS is an arithmetical rule for finding the mean or average time for paying several sums due at separate times: thus, multiply each sum by the number of days, from one day before the first falls due until that sum is due; divide the sum of these products by the whole amount due, and the quotient will be the number of days to be counted from the day before the first falls due.—EQUATION OF TIME is the difference of time between a true sun dial and a true clock, as explained under DAY.

EQUATOR (Lat. *æquo*, to make equal), a circle round the earth midway between the poles, so called because when the sun is vertical over this circle (March 20 and Sept. 20) the day and night are equal in all parts of the world. The celestial equator is a circle in the heavens, midway between the poles. When the sun crosses the celestial equator he is vertical at the equator.

EQUATORIAL, belonging to the equator, a geographical and astronomical term. An equatorial signifies an equatorial telescope, that is, a telescope which revolves on an axis parallel to the axis of the earth, which renders its motion parallel to the plane of the equator. (See OBSERVATORY.)

EQUINOX (Lat. *æquus*, equal, and *nox*, night), the moment when the sun's centre crosses the celestial equator; the vernal equinox being about March 20, and the autumnal about Sept. 20.—**EQUINOCTIAL LINE** is a name sometimes given to the equator.—The **EQUINOCTIAL POINTS** are the points in the celestial equator at which the sun's path crosses the equator; these points move slowly westward, as explained in the article ECLIPTIC; the movement is called the precession of the equinoxes.—**EQUINOCTIAL COLOUR** is a celestial meridian passing through the equinoctial points.

EQUITES (plural of the Lat. *equus*, horse-man), or knights, an order of the people in ancient Rome, which in some respects may be compared with the English gentry. Their origin is attributed by Roman historians to the institution of Romulus, who is said to have selected the first 300 out of the 3 chief divisions of the patricians, and to have divided them into 3 centuries, named Ramnenses, Titienses, and Lucernes, corresponding to similar names of the 3 patrician tribes. Tarquin the Elder added 3 new patrician centuries, and Servius Tullius 12 new ones from among the richest plebeians. They formed a regular military body, being obliged to serve on horseback in time of war, and were divided into *turmæ* of 30 men each, subdivided into tens. They were also called *celeres*, and their chiefs *tribuni celerum*. Politically they seem to have represented an aristocracy of wealth in opposition to the aristocracy of birth, particularly after they became a distinct body of the people by the institutions of Servius Tullius. Under the republic the knights were enrolled by the censors and consuls for a service of 5 years, being supplied by the state with a large sum for the purchase, equipment, and maintenance of a horse, but with no personal pay. Every dictator, immediately after his appointment by the senate, had to select a commander of the horse, called *magister equitum*. During service they had no vote in the assemblies of the centuries. At the time of the siege of Veii, when the want of cavalry was much felt by the Romans, a new body was added to the ancient knighthood, consisting of a large number of young volunteers who offered to enter the ranks at their own expense. The new knights received a regular pay, but had no vote, and no share in many distinctions enjoyed by the old order. Gradually they coalesced into a numerous and wealthy middle class, placed politically and socially between the patricians and plebeians, and were so recognized by a law of Caius Gracchus (123 B. C.). Of the privileges as jurymen which the same laws bestowed upon them, they were deprived by Sylla. At

that period they were generally the farmers of the public revenues, under the name of *publicani*. As such, though their merits are extolled by Cicero, who belonged to their order, they seem to have been despised by the Roman people. Under the empire, owing to the heterogeneous elements of which their increased body was composed, they gradually sank, and in spite of efforts to restore their influence, they disappeared from the stage of political life under the later emperors. In general the history of the Roman knighthood, as a political institution, is involved in great obscurity.

EQUITY. In a general sense, equity is natural right, but as used in jurisprudence it denotes an administration of law with reference to the particular circumstances of a case, in contradistinction to the ordinary method of adjudicating by a rule of general application. This, however, is a theoretical rather than a practical view, for equity as distinguished from strict law is necessarily administered by uniform rules. A judgment founded upon the particular circumstances of a case, without any reference to principles applying in common to such case and to others, would hardly deserve the name of a judicial decision, but rather would be an arbitrary opinion unregulated by legal analogy. In other words, it would be the capricious adjudication of a court not bound by any precedent. This has never been the nature of equity as administered in any country where laws have been prescribed for the regulation of society. At an early period, it is true, many cases would occur which were not provided for by legislation. In these a discretion must be exercised; but every case when decided becomes a precedent, and thus in time the equitable or exceptional law acquires a systematic form and obligation. Another class of cases is where a positive law is productive of some individual hardship not contemplated in the enacting of the law. Relief may then be afforded by the intervention of an equitable power, whose office is not to abrogate or interfere with the operation of the law according to its real intent, but to afford exemption in cases which were probably not foreseen, and therefore could not have been intended. Again, there may be an omission in a law, whether it be statutory or derived from custom, to provide for cases of non-compliance by reason of casualty or some cause not involving serious fault. Thus where forfeitures or penalties are consequent upon the failure of strict performance of an agreement, there is an obvious distinction between intentional neglect and accidental failure, especially if in the latter case it was by inevitable misfortune. There is here room for equitable relief in the one case without impairing the operation of the law in the other, to which alone it justly applies. It is indeed difficult to distinguish with exact precision the line that divides culpable negligence from excusable omission; or again, to determine how far actual disability should be a ground of relief from legal obligation. A man of small capacity for business may

make improvident contracts which he cannot fulfil, or another who has ordinary sagacity may still by accident be deprived of the means of paying debts which he has fairly incurred. Where no fraud is involved, the obligation of contracts cannot as a general rule be abrogated by a court of equity. Hardship will sometimes occur, and there is a natural impulse to give relief in the individual case; but such leniency often repeated is found to be productive of counterbalancing consequences not at first anticipated, and the necessity of a general rule becomes apparent. The discretionary power of the Roman prætor was at first unrestricted. Soon, however, his discretion was brought under certain rules from which he was not allowed to depart. It is true that annually when each prætor went into office he made a formal publication of the rules by which he would be governed in his administration of the laws during his term of office, which might allow the inference that he had an arbitrary liberty to disregard former precedents; but practically it was but the adoption of the edict of his predecessors, with occasional modifications suggested by enlarging experience. The English equity system was early dissevered from the ordinary administration of law, and has ever since remained separate. Yet the equitable principles maintained in the court of chancery could have been applied by the common law courts, and to some extent the latter have been compelled to admit modifications into their practice by analogy to equitable proceedings. Thus the penalty of a bond was formerly held to be the debt, and to be recoverable; yet after the court of chancery gave relief upon the payment of the real debt, which was usually specified in the condition of the bond, the common law courts gave the same relief at any time before judgment; though if payment of the amount really due was not prior to that time tendered, judgment could be entered for the penalty and enforced by execution for the whole amount. A similar change has also taken place with regard to mortgages. (See EQUITY OF REDEMPTION.) Again, the conveyance of lands to uses became a peculiar subject of equity jurisdiction; the use not being recognized at law, but being enforced in chancery. The statute of uses (27 Henry VIII.) was intended to make the use cognizable as the real title in courts of common law, but this effect was defeated by the over-nice scruple of the judges, whereby a limitation of a second use, as if a conveyance was made to A for the use of B, in trust for C, was held not to be within the statute; and the court of chancery again intervened to enforce such second use under the name of a trust, and has ever since retained exclusive jurisdiction of that class of cases in England. Another peculiarity of the English equity system was formerly the right of calling upon the defendant in the action to testify, first by a sworn answer to the complaint, and then by examination upon accounting, and in various other cases, at the election of the complainant. But this distinction has been

superseded by the recent statutory provisions in England and the United States, by which parties are made competent witnesses in all the courts. (See EVIDENCE, and also CHANCERY.)

EQUITY OF REDEMPTION, the interest which the owner of lands retains after having mortgaged them, or rather after the mortgage has become due. By the common law, upon the non-payment of the sum secured by the mortgage at the day when due, there was an absolute forfeiture of the mortgaged property; but courts of equity interfered and compelled the mortgagee upon tender to him of the amount really due to deliver up the premises, and he was also obliged to account for the profits if he had been in possession. At an early period a mortgage was considered to be a conveyance subject to be defeated by the payment of a specified sum at a certain time, the mortgagee being in the mean time entitled to the possession as the legal owner; and even since the change introduced by the courts of equity in respect to the right of the mortgageor to redeem, the old theory has still so far prevailed in England that the right of possession was deemed to pass with the mortgage. Although latterly the mortgageor has usually retained possession until the debt has become due, yet this is only by the assent of the mortgagee; and unless a stipulation to that effect is contained in the mortgage, there is nothing to prevent the mortgagee from maintaining an action of ejectment to obtain possession. Yet notwithstanding this apparent legal ownership, the equitable doctrine is that the mortgageor is the real owner until foreclosure, so far at least that his estate descends to his heirs, or may be devised or otherwise conveyed by him, subject only to the right of the mortgagee, which right is to hold the land as a security for payment of the debt. An incongruity is however still suffered to exist in several particulars. Thus a lease made by the mortgageor can be avoided by the mortgagee, while on the other hand a lease by the mortgagee is subject to the limitation of his estate, and on payment of the mortgage will cease. So the wife of the mortgageor was held not entitled to dower because he had only an equity of redemption, yet the wife of the mortgagee was also excluded on the ground that the estate which he had was in the nature of a trust. But now, by the statute 3 and 4 William IV., c. 105, the equity of redemption is subject to dower and curtesy. In the United States the equity doctrine has been long since carried out with more consistency. The mortgage is considered merely as a security, which can be made available only by a sale under a decree of a court or under a power of sale contained in the mortgage itself. Until such sale the fee of the estate is in the mortgageor, and he has the entire disposition of it, except that the lien of the mortgage will continue as against all persons to whom the lands may descend or be conveyed; the mortgageor retains possession until such sale, unless his right is divested by a court of equity, by reason of the insufficiency

of the mortgaged lands as a security. So the estate of the mortgageor is subject to the lien of a judgment, and may be sold on execution, and his wife is entitled to dower except as against the mortgagee, and even as against him unless she joined in the mortgage. This is on the supposition that the mortgage was made subsequent to marriage; if made before, the dower of the wife would of course be subject to the right of the mortgagee. Such in the state of New York are the incidents of the estate of the mortgageor, usually though not with strict propriety termed the equity of redemption; the same system has been generally adopted in the other states.

EQUIVALENT, CHEMICAL. It is a matter of experience, that when an element enters into chemical combination with another element, it does so in a fixed proportion which may be expressed in numbers. This ratio is termed the combining equivalent, combining proportion, equivalent weight, or simply the equivalent of the element. The term atomic weight is also used synonymously by those who accept the atomic theory. Each of the elements has its own special combining equivalent, and is incapable of uniting with other elements except in this proportion or some multiple of it. The equivalents of compound bodies are represented by the sums of the equivalent numbers of all the elements which enter into their composition. The weights of the equivalents of the elements are ascertained by determining experimentally how much of each is required to replace the others in their combinations with some well-known element, the weight of the equivalent of which has been assumed. Thus, the quantity by weight of each element which unites with one equivalent of oxygen to form a protoxide, analogous to water, is usually considered to represent its equivalent. A knowledge of the exact weights of the equivalents is of the first importance to chemists; all calculations regarding the composition of bodies, as in analysis, or of the quantities of materials to be employed in the manufacture of compounds, being based upon them. As the equivalent numbers express nothing but the relative weights in which the elements unite with each other, it is evident that the weight of any one equivalent may be arbitrarily chosen as a standard to which all the others shall be referred; it is essential only that the relation be strictly observed. Tables of equivalents are thus constructed, in which the equivalent weight of each of the elements is attached to its name. Several standards have been selected by different chemists; only two, however, have ever been generally used. The equivalent weight of hydrogen, being smaller than that of any other element, was regarded as unity by Dalton, who referred all the other equivalents to it. This system has always been generally adopted by the chemists of Great Britain and the United States. It possesses the very great advantage that in it the equivalents are represented by small numbers, many of them without frac-

tions, which are convenient in calculations, and can be easily retained by the memory. Another table, in which the equivalent weight of oxygen is assumed to be 100, has been much used on the continent of Europe. It was proposed by Berzelius, mainly it would seem for the purpose of discountenancing a theory advanced by Prout, that all the equivalent numbers are simple multiples of that of hydrogen; superiority was claimed for it on the ground that as oxygen is the most abundant of all the elements, and since the greater number of bodies studied by chemists are compounds of it, calculations would be simplified if its equivalents were regarded as equal to 100; in which case it is only necessary to add 100, 200, 300, &c., to the equivalent weight of the element with which oxygen is combined, in order to ascertain the equivalent weights of its several oxides. The equivalent of sulphur, a very common element, would also have a simple expression, being equal to 200. These instances, however, do not at all compensate for the high numbers by which the other equivalents must be represented; numbers which cannot be remembered without great difficulty, and which render even the most common calculations extremely laborious unless logarithms are resorted to. Berzelius, who believed that the equivalent numbers should be regarded as entirely accidental and unconnected with each other, desiring to give them the most accurate possible expression, introduced the custom of attaching to them large decimal fractions; indeed, the power to do this which is afforded by the high numbers of his system has always been claimed as one of its advantages. The accuracy of thus employing several decimals, in cases where the process by which the result has been obtained is liable to errors of considerable magnitude, was long since pointed out by Erdmann, who has called attention to the fact that no greater or lesser number of decimals ought to be given than the experiment justifies. All tables of equivalents heretofore published are more or less defective from neglect of this truth. The equivalent numbers have been recently thoroughly investigated and revised by Dumas, who has again brought forward and upheld Prout's theory, which, owing to the vigorous opposition of Berzelius, had found but few supporters of late years. Most of the equivalents thus far studied by Dumas are simple multiples of that of hydrogen. To this rule there are, however, several exceptions; among which some are multiples of $\frac{1}{2}$, while others are multiples of $\frac{1}{4}$ of an equivalent of hydrogen. It may be mentioned that it is still a matter of doubt whether the equivalents of several of the elements should not be regarded as twice, or that of others as $\frac{1}{2}$ of those ordinarily admitted; a change which would greatly simplify certain portions of chemical science. This question has been warmly discussed for several years, and many chemists habitually employ equivalents thus modified; in this article, however, the most common

usage of chemists will be adhered to. The numbers in the annexed table of equivalents have been taken in part from Dumas' memoir, (*Comptes rendus*, xlv., 952), and in part from Kapp and Will's *Jahresbericht für Chemie*, &c., for 1857. For convenience of reference both the hydrogen and oxygen scales are given; the numbers of the latter being readily obtained by dividing those of the former by the fraction $\frac{16}{100}$. The names of those elements which from their variety are comparatively unimportant, are printed in italics; the equivalents of a few of these have not as yet been determined.

Names of the Elements.	Symbols.	Equivalents.	
		H=1	O=100
Aluminum.	Al.	18.75	171.875
Antimony (<i>Stibium</i>).	Sb.	122.00	1525.00

ÉRARD, SÉBASTIEN, a French manufacturer of musical instruments, born in Strasbourg, April 5, 1752, died in Passy near Paris, Aug. 5, 1831. His father, a cabinet maker, dying in needy circumstances, he went to Paris at the age of

16, and apprenticed himself to a maker of harpsichords. Possessing a remarkable inventive faculty, he soon rose to the position of foreman, and his ingenuity bade fair to be of great benefit to his employer, when the latter, moved by jealousy, dismissed him from his service. Another harpsichord maker who had received an order for an instrument, the construction of which baffled his ingenuity, offered him a certain sum to undertake the work, provided only the employer's name should appear in connection with it. The instrument, when completed, excited so much admiration, that the maker was compelled to confess that it was the production of Érard. Attention was at once drawn to the young workman, who was applied to for a variety of new instruments which people wished to have constructed, and who soon after much increased his reputation by the production of a *clavécin mécanique*, or mechanical harpsichord, which contained several improvements on the instruments in use. The duchess de Villeroy, a woman of taste in music, wished to retain him in her service; but preferring his liberty, he declined her flattering offers, and remained in her hotel, where a suitable work room had been fitted up for him, only long enough to execute several ideas which she suggested. It was here, in 1780, that he constructed his first pianoforte, an instrument which, though invented a number of years previous, was then almost unknown in France, and the introduction of which into that country may be said to date from this time. In connection with his brother Jean Baptiste, he soon after established a manufactory of pianofortes in Paris, which gradually became the first in Europe. Among his inventions was an instrument with 2 key boards, one for the piano, and one for the organ; one of which was fitted with a sliding key board for transposing the music, for the use of Marie Antoinette. During the revolutionary period, the brothers Érard went to England, and established a manufactory of pianos and harps in London; but in 1796 Sébastien returned to Paris, and thenceforth his life was passed between that city and London. He constructed the first grand pianos with single action ever made in Paris; subsequently in 1808 much improved the mechanism of the instrument, and in 1823 completed his inventions in this department, by the production of his grand piano with repeating movement. In 1811 his double action harp appeared in London, where it became so popular, that in a single year, instruments to the value of £25,000 were sold. His last important work was the grand organ constructed between 1827 and 1830 for the chapel royal of the Tuileries. During the last 40 years of his life his inventive faculty seemed never idle, and of the 15 or 20 inventions for which he took out patents, not one was perfected without close study and repeated experiments. The celebrity which his instruments have gained remains undiminished, and Érard pianos are still unsurpassed for

roundness, fulness, and beauty of tone.—He was succeeded in the firm by his nephew JEAN BAPTISTE ORPHÉE PIERRE, born in Paris in 1794, died at the chateau La Mucette, Aug. 8, 1855. He possessed much of the inventive skill of his uncle; published in 1849, *Notice sur les pianos d'Érard en Espagne, en Italie, en Suisse, en Russie, &c.*, and rebuilt in 1850 the organ constructed by Sébastien Érard in the Tuileries, which had been destroyed during the revolution of 1830. His death is said to have been caused by grief at the injury done to his estate at Passy by the construction of a railroad. His last work, a piano estimated at \$5,000, was presented by his widow to the lottery opened in behalf of the sufferers by the Crimean war.

ERASMUS, DESIDERIUS, a Dutch theological and classical scholar and writer, born in Rotterdam, Oct. 28, 1467, died in Basel, July 12, 1536. He was the natural son of Gerard Praët and Margaret, the daughter of a physician of Sevenbergen. He himself received the name of Gerard, but afterward assumed its Latin synonyme Desiderius, the Greek translation of which furnished his surname. He was sent first to the school of Gouda, and afterward to the cathedral at Utrecht to become one of the choir boys. At the age of 9 he was transferred to the monastic school at Deventer, where he applied himself with great diligence to the study of the classics. In 1480 both his parents died, and his monastic tutors sent him to the school of Romboldus at Bois-le-Duc, that he might fit himself for the priestly state. For some years he resisted their wishes, and neglected the studies which they arranged for him; but in 1486, after he had been prostrated by a prolonged fever, he was persuaded by a friend who had just come back from Italy to embrace a life so free from excitement and so favorable to study, and entered as a novice into the convent of Stein near Gouda, of which, a year later, he became a regular brother. The discipline of the convent at Stein was not strict, and the distaste which Erasmus showed for ascetic practices was not reckoned as a sin. He was allowed to study in other than theological treatises, and his reputation as a classical scholar was soon widely spread. In 1492 he was selected as a companion by the bishop of Cambray, and was ordained to the priesthood. Erasmus remained with his patron at Cambray 5 years, when he went to study at the college of Montaignu in Paris, where he supported himself with difficulty by taking pupils. His studies were interrupted by serious sickness, which left in him the seeds of a constitutional malady from which he suffered all the rest of his life. On his return from a visit to relatives in Holland, he established himself in Paris as a teacher of classical literature. Among the numerous and distinguished pupils whom his reputation attracted, the one who was able most to befriend him was a young English nobleman, William Blount, Lord Montjoy. By this friend he was promised an annual pension of a hundred crowns if he would take up his residence in England.

His two years' stay in that country was made pleasant by the attentions of the nobility, and the friendship of the most eminent English scholars. He was presented at court, studied at Cambridge and Oxford, became the associate of More and Colet, and added to his previous acquirements a thorough knowledge of Greek. For several years after his return from England he led an unsettled life, teaching in various cities of France and Holland, translating the ancient classics, investigating the text of the Scriptures, and continually increasing his acquaintance with the scholars of Europe. In 1505 he again visited England, received from Cambridge the degree of bachelor in theology, and was presented to Archbishop Warham. The presents received during this visit made it possible for him to realize his long-cherished wish to visit Italy. His stay there lasted nearly 8 years, and was divided between the cities of Turin, Bologna, Padua, Venice, Florence, and Rome. At Turin the degree of doctor of theology was conferred upon him. In Venice he resided with the famous printer Aldus Manutius, while his collection of "Adages" was in press. In Rome he was treated with great regard by the pope. In 1509, on the accession of Henry VIII., he was induced to go back to England. On the journey thither he composed his *Moriae Encomium*, the "Praise of Folly," in many respects his most remarkable work. On his arrival he was received by his friend More, was presented with a living by the archbishop of Canterbury, which he resigned for a pension of £20, and accepted professorships of theology and of Greek at Cambridge. In 1514 he returned to the continent at the invitation of the archduke Charles, afterward Charles V., from whom he received the appointment of royal councillor, with a small salary; a sinecure which allowed him to reside where he chose, and in which he employed his time almost wholly with literary pursuits, correspondence, theological, polemical, and satirical writing, and with editions and translations of many of the less known Greek and Roman classics. With Reuchlin, his only rival as a linguist, he carried on a spirited controversy concerning Greek pronunciation; and the theory which he maintained has, until the present century, been generally received in the schools of Europe. With Luther his dispute was still more sharp. The monk of Wittenberg was at first a warm friend and admirer of the great scholar; but finding that the liberal spirit of Erasmus was not ready to adopt the extreme tenets of the reformers, he at first expostulated with, then ridiculed, and then denounced his former friend as a time-server, a coward, and a foe to true religion. Erasmus was equally unfriendly to the monastic habits and to the subtleties of the scholastic divinity, and exercised his wit on both of these; but he had no love for theological quarrels, and no wish to draw upon himself unpopularity or persecution. He welcomed the reformation as a movement of free thought, but deprecated its excesses. He disliked all dogmatism, as well as

all extravagance in religious rhetoric, and would have the reformers confine themselves to the patent vices of the monks and clergy, leaving aside the possible errors in doctrine. His middle course in regard to the reformation brought upon him the censure of zealots in both parties. In 1521 he had taken up his residence in Basel, where he was presently called on to mediate between the Catholic magistrates and the rising Protestant party. He could only add fuel to the flame by his moderate counsels. The insurrection of Feb. 1529 completed the overthrow of the authorities; the Roman Catholic religion was definitely prohibited in the city, and all who had opposed the new doctrine were compelled to depart. Though Erasmus had already been condemned as a heretic by the college of the Sorbonne, he could not endure the society of the men who were now in power. He changed the place of his residence to Freyburg, where he remained from 1529 to 1535. In vain did the Catholic party try to win him back to full communion, and in vain did the reformers attack him by jest and sarcasm. He answered the libels of Geldenhauer by pungent rejoinders, he evaded the summons to the diet at Augsburg, and his "Retractations," though promised, were never published. He declined more than one tempting offer, and while he was not unwilling to accept additions to his scanty income, did not care to obscure his literary fame by the more imposing dignity of a place in the sacred college. In 1535 he returned to Basel, where an attack of gout compelled him to remain, and where he died in the arms of his friends. His last days were cheered by the friendly visits and messages of distinguished men both of the Protestant and of the Catholic party. In the midst of severe suffering, he was able to retain his calmness, and to pursue his wonted labors. His death was lamented as a public calamity; a long procession of magistrates and students followed his funeral; and the bequest of his whole property to the aged, the poor, and the orphan, seemed to justify the monument which was erected to him in the cathedral at Basel, and which still remains the chief object of interest in that edifice. Erasmus was small in stature, with light hair and light blue eyes. His portrait by Holbein represents his look as sickly and his face as thin and wrinkled. He was fond of luxurious living, but unable from physical weakness to gratify his appetites. His timidity was excessive. He dreaded to stay in the neighborhood of any contagious disease, and, in spite of his rationalistic tendencies, was frequently haunted by superstitious fears. He had a fine native humor, a keen enjoyment of witty discourse, and an accurate eye for every form of beauty. His taste was as refined as his knowledge was prodigious. He was versed in all the studies of his age; in most of them he excelled. His reading was various, but not desultory. His treatises were finished productions, and their style is always clear, flowing, and eloquent. Erasmus aided the reformation rather as a

scholar and critic than as a thinker or reasoner. He exposed the abuses of the convents and the inconsistencies of the scholastic theology, but he produced no new creed and argued in favor of no heretical doctrine. His defence of the right of reason against authority was weak and evasive. But he revived the study of the Scriptures in their original tongue, affirmed the superior value of early Christian testimonies, and gave an impulse to biblical and patristic investigations. He was, it may be said, the most gifted and industrious pioneer of modern scholarship.—Erasmus published in 1516 the first edition of the Greek Testament from manuscripts, which has been regarded as his greatest work. His complete works, with a biography, were published after his death by Beatus Rhenanus (9 vols. fol., Basel, 1540-'41). Another more complete edition was published at Leyden by Le Clerc (10 vols. fol., 1703-'6). Of the "Colloquies," his most famous work, a great number of editions have been published; the best is that of Amsterdam (1650). The *Moria Encomium* also passed through a great number of editions; it was translated into German and illustrated by Holbein; the latest edition is that of Havre (1839). The other most important works of Erasmus are the *Copia Verborum*; the *Adagiorum Collectanea*; the treatise *De Libero Arbitrio*, which was answered by Luther; the *Paraclesis*, an exhortation to the study of Christian philosophy; the volume of *Epigrammata*; the *Antibarbarorum Liber*; *Lingua*, a satirical work; an explanation of the "Apostles' Creed," *Ecclesiastes, sive de Ratione Concinnandi*, in 4 books; and the immense collection of "Epistles," which, perhaps more than any other of his works, show the character of the man. Of his purely classical works, there are editions of Seneca, Suetonius, Aurelius Victor, Ammianus Marcellinus, Eutropius, Quintus Curtius, Cicero *De Officiis*, the "Tusculan Questions," Pliny the Elder, Livy, and Terence, who was his favorite among the Latins, as Plutarch and Lucian were among the Greeks. He also published translations from Xenophon, Isocrates, Euripides, and Libanius, and issued editions of Ptolemy, Demosthenes, and Aristotle. Among his works are also many controversial apologies, scriptural expositions, and liturgical treatises.—The life of Erasmus has been written by Beatus Rhenanus, Melchior Adam, Merula, Scriverius, and Gaye, in Latin; by Henke and Müller in German; by Lévesque de Busigny, Bayle, Ballart, and Nisard, in French; and by Jortin, Knight, and Charles Butler, in English.

ERASTUS (LIEBER), THOMAS, a Swiss physician and theological polemic, born in Baden, Sept. 7, 1524, died in Basel, Dec. 31, 1583. He studied theology and literature in Basel, where he narrowly escaped death by the plague in 1544. He next studied medicine in Bologna, practised this profession with remarkable success, and after being for many years professor of physic at Heidelberg, obtained in 1580 the chair of ethics at Basel. A skilful practitioner,

relying on induction from experience rather than on dogmas and theories, he was a formidable opponent of the reveries of Paracelsus and his disciples. His principal theological controversy was with Dathenus and Beza concerning the doctrine of excommunication. He held that ecclesiastical censures should extend only to divergences in theological opinion, and not at all to vices and immorality, which were civil offences, and properly punishable only by temporal magistrates. In some of his writings he seems to favor the principle that all ecclesiastical authority is subordinate to the civil power, which is the doctrine commonly recognized as Erastianism.

ERATH, a central co. of Texas, comprising part of a fertile and well watered district near the sources of Brazos river; pop. in 1858, 766, of whom 42 were slaves. The surface is generally undulating, but there are some eminences on the S. and N. E. borders. The soil in the valleys is excellent; the uplands are less fertile, but afford good pasturage. Timber of various kinds covers about $\frac{1}{2}$ of the surface. Stephenville is the capital. The county was formed from Bosque and Coryell in 1856.

ERATO, one of the nine muses, daughters of Jupiter and Mnemosyne. In the theogony of Hesiod she holds the 6th place among them. Her name was derived from the Greek word for love, and she was the protectress of nuptial ceremonies, and the muse of erotic poetry. She disputed with Mercury the honor of having invented the lyre.

ERATOSTHENES, a Greek astronomer, geometer, geographer, poet, and philosopher, born in Cyrene in 276 B. C., died about 196. He possessed a remarkable extent of learning and versatility of talent, and was variously named by his contemporaries the "cosmographer," the "measurer of the universe," the "second Plato," and the "pentathlete" or victor in 5 contests, his erudition in each department being thus represented under the figure of a victory obtained over ignorance. He had for masters Ariston the philosopher, Lysanias the grammarian, and Callimachus the poet, and he completed his education in Athens. His fame reached Ptolemy III., king of Egypt, who invited him to Alexandria and intrusted to his care the renowned library of that city. He is said to have died of voluntary starvation, to which he was led by regret for having lost his sight. His most important work, the *Γεωγραφικα*, treated of the nature and form of the earth, which he supposed to be a motionless globe, of its magnitude, and of the countries, towns, lakes, rivers, and mountains which mark its surface. He was the founder of geodesy, and was the first to compute the magnitude of the earth by the astronomical method still in use. (See EARTH.) He suggested the construction of the large *armilla*, or fixed circular instruments, which were long in use in Alexandria, devised a method for discovering the prime numbers, and resolved the problem of the duplication of the cube. Among

his works was one of universal chronology, the fragments of which form the basis of the system adopted by Bunsen in his work on Egypt. He also wrote verses on numerous scientific subjects, a commentary on the astronomical poem of Aratus, and treatises on comedy and on the Homeric poems. A number of other works are attributed to him upon doubtful grounds. None of his writings, excepting a few brief fragments, remain; but Strabo and other later writers made great use of his geographical works.

ERCILLA Y ZUÑIGA, ALONSO DE, a Spanish poet, born in Madrid, Aug. 7, 1533, died about 1595. He was a scion of an ancient Biscayan family, and after the death of his father, Fortunio Garcia, who was a member of the council of Charles V., he resided with his mother, whose family name (Zuñiga) he adopted, at the imperial court, where he was educated as one of the pages of the future Philip II. He accompanied him on his travels abroad, and was in England in 1554 when Philip married Queen Mary. About this time the Araucanians in Chili, whose territory had been invaded by the Spaniards in 1537, rose against them, and many Spanish knights then at the British court volunteered to serve in the war. Ercilla joined this expedition, in which he distinguished himself as much by his prowess on the battle field as by the heroic spirit with which he bore the difficulties attending the wanderings in the wilderness and the painful warfare with its savage inhabitants. In an interval of the war, he had the misfortune to be involved in a duel during a public tournament which was held in honor of the accession of Philip II. to the throne. Ercilla and his antagonist were both ordered to be put to death, and it was not without difficulty that Ercilla's sentence was commuted to imprisonment. This occurrence, however, served rather to increase than to diminish his love of adventures, and he had no sooner recovered his liberty than he set out on another dangerous expedition against the sanguinary Lope de Aguirre. In 1562 he returned to Spain, and shortly afterward resumed the life of a wanderer, travelling several years on the continent of Europe. In 1570 he came back to Spain and married Maria de Bazan, an accomplished lady of the house of Santa Cruz. In 1571 he was made knight of Santiago, was employed on different missions by Philip II., and served for some time as a gentleman of the bed-chamber of Rudolph II., the emperor of Germany. Little is known of the history of his latter years. His literary fame rests upon *La Araucana*, the most celebrated of Spanish epics. It is in 37 cantos, and celebrates the war with the Araucanians, in which the poet himself was engaged. It is remarkable for the accuracy of its historical, geographical, and statistical information, and in the glowing picturesqueness of its descriptions it is unrivalled in Spanish poetry. Cervantes in his "Don Quixote" goes even so far as to declare

it equal to the great epics of Italy. Voltaire in the introduction to his *Henriade* also expresses great admiration of the poem, which, however, he does not seem to have read. Ercilla wrote the first and best part of this poem on the battle field, but did not live to complete it. The first 15 cantos were published in Madrid in 1569, the second part of the poem in 1578, and the third part in 1590. A continuation of the poem in 33 cantos, written by Osorio, appeared in 1597, and has been sometimes printed in connection with the work of Ercilla, to which it is much inferior. The best editions of *La Araucana* are those published at Madrid in 1776 and 1828.

ERDL, MICHAEL PITS, a German savant, born May 5, 1815, died Feb. 25, 1848, officiated as professor of comparative anatomy and physiology at the university of Munich, and left a variety of writings in connection with those sciences. In 1836 and 1837 he accompanied Schubert on his travels to the East, and discovered that the surface of the Dead sea was situated far below the level of the Mediterranean.

ERDMANN, OTTO LINNÉ, a German chemist, born in Dresden, April 11, 1804, and since 1830 professor of chemistry at the university of Leipsic. In 1842 he established a chemical laboratory at Dresden, which is one of the best in Germany. He devoted much time to the chemical analysis of indigo and other dye-stuffs, and his writings embodying the result of his investigations are not only useful to men of science, but also to merchants. A 4th edition of his *Lehrbuch der Chemie*, and a 2d edition of his *Grundriss der Waarenkunde*, appeared at Leipsic in 1852. Beside his other writings, which are contained in the periodical scientific press of Germany, he prepared the 5th edition of Schedel's *Waarenlexikon*, and published in 1827 an interesting treatise on nickel.

EREBUS, one of the oldest gods of the Greeks and Romans, son of Chaos and Night. He was changed into a river, into which he had been precipitated for having assisted the Titans. The term Erebus was frequently applied to a portion of the pagan inferno, a dark and gloomy space beneath the earth, through which the souls of the just passed on their way to enjoy the eternal and delightful life of Elysium.

ERECHTHEUS, or ERICHTHONIUS, the name of a fabulous hero of Attica, or according to some later writers, of two persons, of whom the younger was the grandson of the elder. Homer describes Erechtheus as an autochthon and king of Athens, and the son of Gæa (Earth); he was educated by Minerva. The one whom Apollodorus mentions under this name was the son of Vulcan and Atthis. Minerva, who reared him secretly, gave him in a chest to Pandrosos and her sisters, who, opening it from curiosity, saw in it a serpent, were seized with madness, and threw themselves down the Acropolis or into the sea. Having expelled Amphictyon, he became king of

Attica, established the festival of the Panathenæa, and founded on the Acropolis the temple which after him was called the Erechtheum. By his wife Pasithea he had a son whom he named Pandion. He is also said to have decided the dispute between Minerva and Neptune for the possession of Attica, in favor of the goddess, and to have introduced the use of chariots with 4 horses, for which he was set among the stars as Auriga. The myths connected with the life of the second Erechtheus are the Eleusinian war, the sacrifice of one of his daughters, and the suicide of the three others, in consequence of a response of the oracle, and his being killed by Jupiter with a flash of lightning, at the request of Neptune. The Erechtheus of Diodorus came from Egypt with grain in time of famine, was made king, and established the Eleusinian festivals. Another Erechtheus, the son of Dardanus and father of Tros in Ilium, is fabled as the richest of mortals, in whose fields grazed 3,000 beautiful mares.

EREGLI, or EREKLI (anc. *Heraclea*), a seaport town of Asiatic Turkey, on the Black sea, pop. 5,000. It has a good harbor, and exports timber, silk, and wax, in exchange for colonial produce, tobacco, and iron. Ship-building is carried on to some extent. A few traces are found here of the ancient Heraclea, which was a town of considerable importance, and noted as one of the stations of the 10,000 Greeks under Xenophon. Near this town is a coal field extending for about 80 m. along the shore of the Black sea. The coal mines are worked under the direction of 2 English engineers, yielding about 50,000 tons annually. There are 2 other towns of the same name, one situated in the district of Konieh, in Asiatic, and the other in the district of Gallipolis, in European Turkey. The latter has a harbor, and is the see of a Greek bishop.

EREMACAUISIS (Gr. *ηρεμα*, by degrees, and *καυσις*, a burning), the name given by Liebig to the slow combustion or oxidation which takes place in organic substances when exposed to the influence of the air, and which results either in the formation of the pulverulent brown substance called humus, as in the decay of woody fibre, or in some more highly oxidated compounds, as when alcohol is converted into acetic acid. It is the first change in the processes of fermentation and putrefaction, and is prevented by any causes that arrest these. The oxygen of the air first acts upon the hydrogen contained in the organic substances, the carbon usually exhibiting no tendency to unite with it until the substance has been raised to a high temperature. Moisture in the air expedites the process, and in some instances exposure to the action of alkaline bodies, and in others contact with other decaying substances, is necessary to induce it.

ERETRIA, an ancient city of the island of Eubœa, situated a little south of Chalcia, whose rival it was in commerce. It was founded prior to the Trojan war, and at an early period be-

came rich, powerful, and one of the chief maritime states of Greece. It was early engaged in disputes with the Chalcians, and for having given assistance to the Ionic cities of Asia in their revolt from Persia it was razed to the ground by the Persians in 490 B. C. It was soon rebuilt S. of the old site, and took part in the Peloponnesian war. The philosopher Menedemus, a disciple of Plato, here established a celebrated school of philosophy. The ruins of this city are still visible.

ERFURT, a circle of the Prussian province of Saxony, bounded N. by Hanover and Brunswick, E. by Merseburg and Saxe-Weimar, S. by Saxe-Gotha, Saxe-Meiningen, and Saxe-Weimar, and W. by Hesse-Cassel; area, 1,806 sq. m.; pop. 346,000. About half the land is arable, and the chief products are corn, tobacco, hops, seeds, and salt. Great numbers of cattle are also raised, and mines of copper, lead, and iron are worked in the circles of Weissensee and Schleusingen. Manufactories of iron, cotton, and woollen fabrics, and many miscellaneous articles, are numerous.—ERFURT, the capital of the above province, and of Thuringia, is situated on the Gera, about midway between Gotha and Weimar; pop. 33,800. It was formerly a city of considerable importance, having at the end of the 16th century had nearly 60,000 inhabitants. It is a fortress of the 2d class, and derives great strategical importance from its situation on the military high road of central Europe. The fort of Petersberg within the walls, and the citadel of Cyriaksburg without, contribute to its strength. Erfurt contains 14 places for Protestant worship, several Roman Catholic churches, and a synagogue. The cathedral, originally a fine Gothic structure, has suffered much from war, but has been repaired by the kings of Prussia within the present century. It contains one of the most massive bells of Germany, called *Maria Gloriosa*, and in popular parlance *Susanna*, this having been the name of the bell melted during the fire in 1251. Of the many convents which existed here till very recently, one only remains, the Ursuline nunnery, with a school conducted by the nuns. The finest modern churches are the *Barfüsserkirche* and the *Augustinerkirche*. The most interesting religious building of Erfurt is the Augustinian convent, in which Luther lived for several years. The convent is now used by the *Martinestift* as an asylum for orphans and for other charitable purposes. Luther's cell is well preserved, and contains his portrait, Bible, and other relics. The university, opened in 1392, and once the 4th in Germany, was closed in 1816. The royal academy of popular sciences is remarkable for its extensive library. The congress of Erfurt (Sept. 27 to Oct. 14, 1808) was attended by Napoleon, Alexander of Russia, and many German sovereigns. In 1813 the town was taken by the Prussians, after a bombardment which destroyed 188 houses. From Nov. 24, 1848, to Aug. 4, 1849, the town was placed in a state of siege; and in March and April, 1850, the *Unionsparlament*,

or Erfurt parliament, was held there in the church of St. Augustine.

ERGOT (Fr. *ergot*, cock's spur), a protuberance which grows out in a curved form resembling a cock's spur from among the grains of the plants of the *graminaceæ*, or grass tribe, as wheat, barley, and especially rye. As it is most commonly met with in the last, the substance has been known by the name of spurred rye (*secale cornutum*). Its origin has been ascribed to various causes. Some have thought it to be the seed altered by a diseased growth, caused by the attack of an insect, or by unfavorable circumstances of moisture, heat, &c. De Candolle thought it a fungus occupying the place of the seed, and called it *sclerotium clavus*. But the evidences are now generally regarded as conclusive of its being the grain itself, diseased and deformed by the influence of a parasitic fungus, attached to it from its earliest development. This fungus, distinguishable by the microscope, has been detected in other parts of the plant; and the white dust or *sporidia* on the surface of the ergot will engender the disease in other plants if scattered in the soil at their roots or applied to the grains.—Ergot as collected for medicinal purposes is in solid grains from $\frac{1}{4}$ to $1\frac{1}{2}$ inches long, of cellular structure, the cells containing oily particles. Its aqueous infusion is claret-colored, has an acid reaction, and possesses the peculiar properties of the substance. It was early used in medicine to expedite parturition by promoting the contraction of the uterus. It possesses poisonous qualities, and when the grain contaminated with it has been employed in making bread, as has sometimes occurred in France, terrible epidemics have followed its use.

ERIO IX. (according to some historians VIII.), king of Sweden, called after his death St. Eric, the son of "a good and wealthy yeoman" (in the words of an old Swedish chronicle) named Jedward, died May 18, 1160. His mother was Cecilia, sister of a former king. His wife was Christina, also of royal blood. He was elected to the throne of the Upper Swedes, or as it was called the "royal chair of Upsal," in 1150; and was the first sovereign in Sweden who saw Christianity firmly established in Upper Sweden. With a view to the spread of Christianity he undertook a crusade against the heathens of Finland; and by transplanting Swedish colonists thither, laid the foundation of the conquest of that country. On his return to Upsal, he was attacked by a Danish prince, Magnus Henrikson, and in the battle that followed, at East Aras (modern Upsal), he fell covered with wounds. His virtues and the austerity of his life procured him the reputation of a saint; but he was never canonized. His rule, which at first extended only over Sweden proper (or Upper Sweden), subsequently embraced Gothland (Lower Sweden). The effigy of St. Eric is preserved upon the arms of the city of Stockholm; and his remains, long the objects of veneration, are in the cathedral of Upsal.

ERIO XIV., king of Sweden, the son and successor of Gustavus Vasa, born Dec. 13, 1533, died Feb. 26, 1577. In youth he was distinguished for his handsome person, his intelligence, and numerous accomplishments; but his passionate and suspicious disposition and immoderate indulgence in pleasure, early awakened the apprehensions of his father. Toward his brothers, who had been created dukes by the king jointly with himself, with the government of certain provinces, he always entertained feelings of jealousy and hostility. He succeeded to the throne in 1560, inheriting from his father the good will of his people, a full treasury, and a prosperous and happy kingdom, and inaugurated his reign by expending what seemed to the Swedes incredible sums on the festivals and pageants attending his coronation. Gustavus had shortly before his death made overtures of marriage to Elizabeth of England in behalf of his son; and the latter, beside keeping alive these negotiations, opened similar ones with Mary, queen of Scots, the princess Renée of Lorraine, and the princess of Hesse. He avoided the embarrassment which a favorable reply to his several offers might have caused by marrying Katrina Mänsdotter, the daughter of a petty officer of his guards, whose beauty attracted his notice as she was selling fruits in the market place of Stockholm. Katrina seems to have been sincerely attached to Eric, and remained true to him amid all his succeeding misfortunes. During nearly his whole reign he was engaged in wars with Denmark and Poland, in the course of which the Swedes acquired from the latter country the Baltic provinces of Livonia and Revel, although at great cost of men and money, whole provinces having been depopulated to supply the army. The animosity of the king toward his brothers increased with years, and finally led to violent measures. John, the eldest, was besieged in his castle at Abo, and condemned to a long imprisonment, and the others were in constant fear of their lives. Eric gradually surrendered himself to a career of tyranny under which the whole kingdom groaned. Assassination became frequent, and under the influence of the royal favorite, Göran Pehrsson, some of the oldest nobility, including the Sture family, were put to death. In the midst of these excesses he was attacked by a fit of madness, the effect of remorse, and for several days wandered alone in the forest. His oppressed brothers John and Charles having at length risen in rebellion, he marched to meet them, and after a desperate conflict was overcome and captured in 1568. He was deposed by act of the Swedish diet, and after languishing 9 years in prison, was poisoned by order of his brother John, who had succeeded to the throne. In the beginning of his reign Eric displayed energy and legislative skill, and made several judicious reforms in the civil and ecclesiastical government of the kingdom. He was a patron of art and science, and was the first to

introduce the titles of baron and count into Sweden.

ERICSSON, John, a distinguished inventor and engineer, born in the province of Wermland, Sweden, in 1803. The son of a mining proprietor, his earliest impressions were derived from the engines and machinery of the mines. In 1814 he attracted the attention of the celebrated Count Platen, the intimate friend of Bernadotte, and being appointed a cadet in the engineers, was employed as a *nivelleur* at the grand ship canal, where he set out the work for more than 600 soldiers. In 1820 he entered the Swedish army as an ensign, and was soon promoted to a lieutenancy. His regiment being stationed in the northern highlands, where an accurate government survey was in progress, Ericsson surveyed upward of 50 miles of territory, detailed maps of which, executed by his own hands, are yet in the archives of Sweden. In 1826 he obtained leave of absence for a visit to England, with the view of introducing his invention of a flame engine, which he had exhibited in a machine of about 10 horse power. This engine did not meet his expectations, and involved heavy expenditures, which induced him to resign his commission, and devote himself to mechanical pursuits. Numerous inventions followed, among which may be mentioned the steam boiler on the principle of artificial draft, for the introduction of which Ericsson joined the established mechanical house of John Braithwaite. After having been applied to numerous boilers for manufacturing purposes in London with success, effecting a great saving of fuel and dispensing with the huge smoke stacks, this invention was applied to railway locomotion on the Liverpool and Manchester railway in the fall of 1829. The directors had offered a prize for the best locomotive engine, and within 7 weeks of the time of trial Ericsson heard of the offer, planned an engine, executed the working drawings, and completed the machine. The lightest and fastest engine started on this occasion was the Novelty, which, guided by its inventor Ericsson, started off at the rate of 50 miles an hour. The principle of artificial draft, which characterized this engine, is yet retained in all locomotive engines; but a different mode of producing it was accidentally discovered so soon after the display of the Novelty, that the original inventor derived no advantage from it. The lightness and compactness of this boiler led to many new applications of steam, and among others to Ericsson's construction of a steam fire engine, which was entirely successful. A similar engine of greater power he subsequently constructed for the king of Prussia. For this invention he received the prize medal of the mechanics' institute of New York. In 1833 he reduced to practice his long cherished project of a calorific engine, and submitted the result to the scientific world in London. The invention excited very general interest, and lectures were delivered in explanation and illustration of its prin-

ciple by Dr. Lardner and by Professor Faraday. Dr. Andrew Ure, having witnessed its performance, was liberal and daring enough to say that the invention would throw the "name of his great countryman James Watt into the shade." Sir Richard Phillips records that he saw the first model machine of 5 horse power with "inexpressible delight;" but the high temperature so affected its working parts that it was not available as a practical machine. Ericsson's attention was next directed to navigation, the result of which was the invention of the propeller, and of that new arrangement of the steam machinery in ships of war which has revolutionized the navies of the world. Ericsson sought to bring these inventions to the favorable notice of the British admiralty, and was listened to with polite but incredulous attention. He took their lordships on a trial trip in a vessel constructed with his new propeller, but he could not induce them to believe what they saw. He found a more confiding listener in Capt. R. F. Stockton of the U. S. navy, by whose influence with the administration of that time at Washington, he was placed in a position to carry out his plans. In 1839 Ericsson came to New York. In 1841 he was employed in the construction of the U. S. ship of war Princeton, on the very plan which had been received with such indifference by the British admiralty. She was the first steamship ever built with the propelling machinery under the water line and out of the reach of shot. Mr. Mallory of Florida asserted, in a recent debate in the senate of the United States, that the Princeton was the foundation of the present steam marine of the whole world; and that, hereafter, in maritime war, those who send sailing vessels to sea, send them but to be captured. The Princeton was distinguished for numerous mechanical novelties beside the propeller; among which were a direct-acting steam engine of great simplicity, the sliding telescope chimney, and gun carriages with machinery for checking the recoil of the gun. In the U. S. division of the industrial exhibition of all nations in London in 1851, Ericsson exhibited the distance instrument, for measuring distances at sea; the hydrostatic gauge for measuring the volume of fluids under pressure; the reciprocating fluid meter for measuring the quantity of water which passes through pipes during definite periods; the alarm barometer; the pyrometer, intended as a standard measure of temperature from the freezing point of water up to the melting point of iron; a rotary fluid meter, the principle of which is the measurement of fluids by the velocity with which they pass through apertures of definite dimensions; and a sea lead, contrived for taking soundings at sea without rounding the vessel to the wind, and independently of the length of the lead line. For these he received the prize medal of the exhibition. In 1852 he was made knight of the order of Vasa by King Oscar of Sweden. In the same year he brought out a new form of

caloric engine in the ship Ericsson. It propelled this ship of 2,000 tons from New York to Alexandria on the Potomac, in very rough weather, in the latter part of Feb. 1853. On this trip the engines were in operation for 73 hours without being stopped for a moment, and without requiring the slightest adjustment, the consumption of fuel being only 5 tons in 24 hours. At Alexandria she was visited by the president and president elect, the heads of departments, a large number of naval officers, and many members of both houses of congress, and subsequently by the foreign ministers in a body, and by the legislature of Virginia, then in session. Ericsson was invited by a committee of the legislature to visit Richmond as the guest of the state. The secretary of the navy recommended, in a special communication to congress, the passage of a resolution authorizing him to contract for the construction of a frigate of 2,000 tons to be equipped with caloric engines, and to appropriate for this purpose \$500,000. This recommendation failed in consequence of the pressure of business at the close of the session. But notwithstanding the surprise and admiration that this achievement excited in the scientific world, the speed attained was not sufficient to meet the practical exigencies of commerce; and the repetition of the engines on this large scale could not be undertaken at the charge of individuals. In the midst of numerous mechanical pursuits, Ericsson has since devoted himself to perfecting the caloric engine. Step by step he has been advancing to admitted success, has developed his invention in machines with cylinders varying from a diameter of 6 inches to one of 32 inches, and is still engaged in adapting it to all the various uses which call for it. It is now applied to purposes of pumping, printing, hoisting, grinding, sawing, turning light machinery of various kinds, working telegraphic instruments and sewing machines, and propelling boats. More than 200 of these engines are in successful operation. The extent of power attainable has not been ascertained. Ericsson still labors with the vigor and enthusiasm of boyhood. While engaged in carrying out his inventions, it is a common thing for him to pass 16 hours a day at his table, in the execution of detailed mechanical drawings, which he throws off with a facility and in a style that have probably never been surpassed. (See also ATMOSPHERIC ENGINE.)

ERIDANUS, the Greek name of a large northern river which Æschylus confounded with the Rhone, but which later writers made identical with the Roman Padus, or modern Po, the chief river of N. Italy. According to Hesiod and the tragic poets, Phaëton, son of Helios, in a futile attempt to guide the chariot of his father, was struck with a thunderbolt by Jupiter, and fell into this river. His sisters, the Heliadæ, were changed into poplar trees, and their tears into amber, for which this river was chiefly famous. The name was also given to a river of Attica, which flowed into the Ilissus, near Athens.

ERIE, the name of counties in 3 of the United States. I. A W. co. of N. Y., bordering on Lake Erie, bounded N. by the Tonawanda and S. by the Cattaraugus creek; area, about 950 sq. m.; pop. in 1855, 152,407. It is drained and supplied with water power by Buffalo creek and several other small streams. In the N. part the surface is undulating, and the soil well adapted to grain; in the S. it is hilly, and here the land is more suitable for grazing. Wheat, oats, and grass are the staples. The productions in 1855 were 285,726 bushels of wheat, 724,747 of oats, 483,228 of Indian corn, 98,011 tons of hay, 1,866,132 lbs. of butter, and 2,038,392 of cheese. There were 3 manufactories of agricultural implements, 9 furnaces, 9 woollen mills, 43 grist mills, 151 saw mills, 31 newspaper offices, 155 churches, and 309 school houses. Iron ore, limestone, brick clay, and water cement are found in considerable quantities. The county is traversed by 6 railroads, and by the Erie canal, which connects with Niagara river at Black Rock, and has its terminus at Buffalo, the county seat. Organized in 1821, and named from Lake Erie. II. A co. of Penn., forming the N. W. extremity of the state, bordering on New York, Ohio, and Lake Erie; area, 740 sq. m.; pop. in 1850, 38,742. With the exception of a high ridge, several miles distant from the lake, and running nearly parallel with its shore, the surface is generally rolling and well watered. Its soil is clayey, and in the N. part produces good crops of grain. The S. portions of the county are mainly occupied by pasture lands. Grain, potatoes, maple sugar, lumber, and dairy produce are the staples. In 1850 the productions were 433,692 bushels of Indian corn, 147,825 of wheat, 433,765 of oats, 171,855 of potatoes, 69,422 tons of hay, 252,843 lbs. of butter, and 333,748 of maple sugar. There were 57 churches, 5 newspaper offices, and 9,343 pupils attending public schools. Iron is the principal mineral; slate and sandstone underlie much of the surface. Formed in 1800, and named from Lake Erie, which forms its entire N. W. boundary. Capital, Erie. III. A N. co. of Ohio, bordering on Lake Erie and Sandusky bay; area, 250 sq. m.; pop. in 1850, 18,568. It is drained by Huron and Vermilion rivers, and crossed by several railroads. Near Huron river are several ancient mounds and enclosures, and at Sandusky are extensive quarries of valuable limestone. The surface is generally level, the soil alluvial and exceedingly fertile. Grain, hay, wool, butter, and fruits are the chief staples. In 1858 the principal productions were 601,713 bushels of Indian corn, and 118,181 of wheat. Capital, Sandusky City.

ERIE, a city and the seat of justice of Erie co., Penn., situated on Lake Erie, nearly midway between Buffalo and Cleveland, on one of the finest harbors on the lakes, Presque Isle bay, nearly 5 m. long, and over half a mile wide; pop. in 1840, 3,412; in 1850, 7,290; in 1859, between 10,000 and 12,000. It is one of

the principal ports on the lake, and the only important one belonging to Pennsylvania. The city stands upon an elevated bluff commanding a fine view of the lake and harbor. The streets are broad and regularly laid out at right angles, and near the centre of the city is a large and beautiful park. The custom house and post office occupy a handsome marble structure, which cost about \$100,000. There are 13 churches, 2 very large first class hotels, a flourishing academy, a public library, 7 newspapers, a bank and numerous banking offices, several large flouring mills, factories of various kinds, and 2 extensive founderies and machine shops, at one of which railroad cars are manufactured. The public schools are among the best in the state. A heavy trade in coal, lumber, and staves is carried on, which gives employment to a large number of vessels and men. Large quantities of whitefish and lake trout are caught and shipped from this point. They are taken with gill-nets in deep water a few miles N. of the harbor. The Lake Shore railroad passes through the city. The Sunbury and Erie railroad, which connects Erie with Philadelphia, and which (June, 1856) is rapidly approaching completion, and the Erie and Pittsburg railroad, part of which is in running order, have their termini here; and a line called the Erie city railroad, an extension of the New York and Erie railroad, has been projected. Erie is connected with the Ohio river by the Erie extension of the Pennsylvania canal. The town possesses great commercial advantages, and will probably ere long be the 3d in size and importance in Pennsylvania. It would have occupied this position already, but for a disastrous contest in 1853, '54, and '55 with the railroads, known as the "Erie railroad war." Erie is included in the collection district of Presque Isle, the foreign commerce of which for the year ending June 30, 1858, was as follows: value of exports, \$49,160; of imports, \$1,846; entrances, 73 vessels of 11,498 tons; clearances, 74 vessels of 10,365 tons. The enrolled and licensed tonnage of the district was 7,744. In 1794 Gen. Wayne, when on his way to the Maumee, established a garrison here; and on his return in 1796 he died in a small log cabin, and was buried at the foot of the flag-staff. His remains were removed by his son in 1809 and taken to Delaware county. The most prominent event in the history of Erie was the building and equipping of Perry's fleet during the war of 1812-15.

ERIE, LAKE, the most southern of the 5 great lakes of the N. United States and of Canada, and the lowest of the chain, except Lake Ontario, which lies below it to the N. E. The boundary line between the two countries passes through these waters. Both the lakes named lie nearly in the extension of the line of the river St. Lawrence, the outlet of all these bodies of fresh water. The mean length of Lake Erie is estimated at 240 m.; mean breadth, 40 m.; elevation above the level of the sea, 565 feet; area, 9,600 sq. m. Its surface is 338 feet above that of Lake Ontario, this great descent being made

in the Niagara river, which connects the two lakes. The form of the lake is not very irregular, its maximum length exceeding the mean by only about 15 m., and the breadth varying from 80 to 60 m. Its western extremity receives from the N. the waters of the upper lakes, discharged by the Detroit river. At this extremity are many islands clustered together, the largest one about 14 m. in circumference. They are well wooded, with a fertile soil derived from the limestone rocks of which they are composed, and to some extent they are under cultivation. The peculiar features of Lake Erie are its shallowness and the clayey nature of its shores. While Lakes Huron and Michigan present a maximum depth of 1,800 feet, Lake Superior a mean depth of 900, and Lake Ontario of 500 feet, the maximum soundings in Lake Erie, except near its lower end, rarely exceed 120 feet. The U. S. engineers found 3 divisions in the floor of the lake, of increasing depth toward the outlet. The upper portion, above Point Pelee island, has a level bottom with an average depth of 30 feet. The middle portion takes in the principal part of the lake, extending to Long Point. The bottom is here level also, and from 60 to 70 feet below the surface. Below Long Point the depth varies from 60 to 240 feet. Its bottom is a light clayey sediment, which rapidly accumulates, as noticed in the account of the diving operations for the recovery of the safe of the steamer *Atlantic*. (See *DIVING*.) The material is derived from the wearing away of the strata that compose its shores. On the S. side, from the mouth of the Cattaraugus in New York, near the E. extremity of the lake, through the strip on its coast belonging to Pennsylvania, and almost to Sandusky in Ohio, the rock formations are the Portage and Chemung groups of the New York system, a series of easily disintegrated blue, gray, and olive shales, associated with beds of gray sandstone. The western extremity and whole N. coast is made up of the limestones of the Helderberg group, which by their decomposition form a clayey and muddy soil. Sandstones, too, are associated with these. Both sides thus furnish the materials for sediments of a nature to be readily distributed throughout the lake. Along the coast the loosely aggregated products of the disintegrated strata are frequently seen forming high cliffs, which extend back into elevated plateaus. The rivers cut deep channels through these, discharging the excavated matters into the lake. The underground water courses penetrate through the base of the cliffs and undermine them, and the waves aid to break them down. Slides are of frequent occurrence. The water takes up the earthy materials, and is rendered turbid by them a long way out from the land. This may be seen on both sides the lake; and about Cleveland in Ohio, the wearing back of the coast line has been particularly remarked. For 40 m., extending E. to Fairport, the shores are of this character, the stratified clays and sand

forming a terrace, the height of which at Cleveland is 103 feet above the water. Owing to the shallowness of the lake, it is readily disturbed by the wind; and for this reason, and for its paucity of good harbors, it has the reputation of being the most dangerous to navigate of any of the great lakes. Long continued storms, with the wind setting from one extremity of the lake toward the other, produce disastrous effects upon the land to leeward by the piling up of the waters. From this cause the city of Buffalo at the foot of the lake has suffered serious damage in its lower portions. The return of the waters after the storm has in some instances been so rapid, when driven along by a wind setting in the same direction, that powerful currents are produced. In Oct. 1833, a current thus caused burst a passage through the peninsula on the N. coast called Long Point, and excavated a channel more than 9 feet deep and 900 feet wide. The natural harbors around the lake are few, and these have required artificial improvement. They are generally at the mouths of the small rivers which flow into the lake, the channels of which are carried far out into the lake by piers, constructed on one or both sides. Erie in Pennsylvania has a large natural harbor, formerly known as that of Presque Isle, which has been protected by a breakwater. The principal harbors on the S. side are those of Cleveland, Sandusky City, and Toledo. On the N. shore there is a harbor called Port Maitland, at the entrance of Grand river near the E. end of the lake, and this river is navigable for small vessels for some distance. Other harbors on the same side are Ports Dover, Burwell, and Stanley; the last the most important, as the port of the productive region of this portion of Canada. Lake Erie drains but a narrow margin of country around it, and receives no rivers of importance. The Maumee is the largest on the American side, entering the lake at its S.W. extremity, its course being nearly on the extended line of the river St. Lawrence and the two lakes Ontario and Erie. Sandusky river, further E. in Ohio, rises about 60 m. to the S. of the lake; but more to the E. the rise of the surface to the N. reaches nearly to the lake shore, determining the drainage in the opposite direction, which is that of the general slope of the strata. The lake was early navigated by sailing vessels built upon its shores. As many as 7 steamers were running upon it in 1830, and not long afterward it became the great thoroughfare of travel between New York and the N. W. states, the steamboat lines running from Buffalo to Chicago. The construction of railroads, upon which travel is more direct and uninterrupted in winter, has caused these lines to be disused. The lake is usually closed to navigation in the early part of December, and continues more or less frozen over till March or April. In the season of navigation an immense amount of transportation is done upon it, and its commerce has been estimated to amount to the annual value of \$220,000,000.

In the year ending June 30, 1858, there were built at the American ports on the lake 136 vessels; and on July 1 of the same year the registered tonnage of these ports was 57,111 tons. On the American side there are 26 light-houses and beacons, and on the Canadian side 10. The communication with Lake Ontario is through the Welland canal, constructed across the Canadian peninsula. The fisheries of Lake Erie are of little importance compared with those of the upper lakes, where the same kinds of fish are more abundant and of better quality. The chief varieties taken are lake trout and whitefish; other varieties are sturgeon, sisquit, muskelonge, black bass, white bass, and Oswego bass, several species of pike, &c.—**BATTLE OF LAKE ERIE.** In the war of 1812 between the United States and Great Britain, the naval superiority on Lakes Erie and Ontario became an object of much moment to the belligerents, and corresponding efforts were made on both sides to secure it. The general command of the American naval forces in these lakes was held by Commodore Isaac Chauncey, who was employed on Lake Ontario, while the immediate command on Lake Erie was given to Master Commandant Oliver Hazard Perry of Rhode Island, who at the time he was assigned to this important service was only 27 years of age. A squadron of 9 sail was equipped by Perry at Erie. The enemy had command of the lake, and maintained a close blockade of the port while the squadron was preparing for service, and had they been more enterprising would doubtless have destroyed it before it was ready. Early in Aug. 1813, Perry managed to get his squadron out of the port, which was effected with great difficulty; and on the morning of Sept. 10, while lying in Put-in bay, a harbor among the Bass islands, near the W. extremity of the lake, he discovered the British squadron in the offing, and immediately went out to meet it. This squadron consisted of 6 sail, commanded by Commodore Robert Heriot Barclay, an officer of experience, who had served under Nelson at Trafalgar. As the Americans stood out, it was discovered that the enemy had hove to on the port tack in a compact line ahead, the wind light from the S. E. The British line was composed as follows: The schooner Chippeway, of 1 long 9-pounder; the flag ship Detroit, of 19 guns, principally long 24 and 12-pounders; the brig Hunter, of 10 guns of light calibre, principally long 6 and 4-pounders, and 12-pound carronades; the ship Queen Charlotte, of 17 guns, long 12s and 9s and 24-pound carronades; the schooner Lady Prevost, of 13 guns, long 9s, 6s, and 12-pound carronades; schooner Little Belt, of 3 guns, 1 long 12-pounder and 2 long 6s; in all, 6 vessels, mounting 63 guns, with 502 officers and men. Perry so formed his line as to bring the heaviest of his vessels opposite the heaviest of the enemy. Selecting the flag ship Detroit as his antagonist, he took the lead in the Lawrence brig of 20 guns, 2 long 12s and 18 32-pound carronades. The

schooner Scorpion, Sailing Master Champlin, mounting 1 long 24 and 1 32-pound carronade, was stationed ahead of the Lawrence, and the schooner Ariel, Lieut. Packett, of 4 short 12-pounders, on her weather bow. The brig Caledonia, Lieut. Turner, of 3 long 24-pounders, came next to engage the Hunter. The Niagara, Master Comdt. J. D. Elliott, of 20 guns, 2 long 12s and 18 32-pound carronades, came next to engage the Queen Charlotte. The Somers, Sailing Master Almy, 2 long 12-pounders; the Porcupine, acting Sailing Master Senat, 1 long 32-pounder; the Tigress, Lieut. Conklin, 1 long 24-pounder; and the Trippe, Lieut. Holdup, afterward Captain Thomas Holdup Stevens, 1 long 32-pounder, were stationed in the rear to engage the Lady Prevost and Little Belt. In all, 9 vessels, mounting 54 guns, with 490 officers and men. Of these 9 vessels, two only, the Lawrence and Niagara, could be considered regular vessels of war. The others, having for the most part been built for commercial purposes, were very slight and without bulwarks. The guns of the Americans were generally of heavier calibre than those of the British squadron, though they were 9 fewer in number. The force of the British as to weight of metal has been variously stated, though all accounts agree as to the vessels and the number of guns. It seems beyond doubt that the two squadrons were of nearly equal strength. Perry's line was formed about 10 A. M., when it bore up for the enemy; the Lawrence bearing at her main a square blue flag, upon which were the dying words of Lawrence: "Don't give up the ship." The day was beautiful and very bright, and the lake perfectly smooth. The American squadron steered for the head of the British line, upon a course which formed an angle of about 45° with it. At about 11 h. 45 m. the Detroit opened her fire upon the Lawrence; signal was now made for each vessel to engage her designated opponent, and in a few minutes the action with the leading vessels became general and extremely severe. The British fire seems to have been at first principally directed upon the Lawrence, which suffered terribly. At 2 h. 30 m., out of 101 persons who composed the complement of that vessel when she went into action, there were only 18, including Perry himself, not disabled; 22 had been killed, 61 wounded, and every gun rendered ineffective by shot. In this desperate condition of his own vessel, Perry determined to shift his flag to the Niagara; and leaving the Lawrence in command of Lieut. Yarnall, he started in his boat for that vessel, then about half a mile to windward. His passage to her was a perilous one, the shot falling thickly around his boat, and covering her crew with spray. The Lawrence continued to be the main object of the enemy's fire, and being reduced to a mere wreck, was compelled to strike soon after Perry left her. Later in the engagement, however, her colors were again hoisted. As Perry crossed the gangway of the Niagara, Capt. Elliott

teered to bring up the small vessels, which, to the lightness of the wind, and their dull sailing, had as yet taken but little in the engagement. Perry gladly acceded to his proposition, and Elliott immediately left the Niagara to execute it. At this moment he was about 500 yards to windward of the main force of the enemy, nearly abeam of Detroit, and had suffered very little. Perry, on seeing the signal for close action to be made, moved up, and passed through the enemy's line, fighting for some time at close quarters, with destructive effect, the Detroit and Queen Charlotte, which at this critical moment had fouled each other. The Caledonia, and the smaller vessels which had now come up, were closely engaged with the British to windward; and their ships being thus under a heavy cross fire, the Detroit, Queen Charlotte, Lady Prevost, and the Scorpion were struck at 8 o'clock, their colors coming down about 7 minutes after Perry opened his fire with the Niagara. The Chippeway and the Belt endeavored to escape to leeward, but were pursued by the Scorpion and Trippe, and finally, in which vessels they surrendered about an hour after the action.

On taking possession of the British vessels they were found to be very much cut to pieces, especially the Detroit and Queen Charlotte. Their loss was 41 killed, including the gallant Capt. Finnis of the Queen Charlotte, and 100 wounded, 9 of whom were officers. Commodore Barclay was carried below severely wounded in the action, but soon returned to his quarters where he remained until he received another serious wound by a grape shot in the right leg. Toward the close of the action, he was informed that further resistance was impossible, this heroic officer caused himself to be carried on deck, that he might be convinced of the fact by personal observation. The American vessels also suffered severely. Their loss was 27 killed, including Lieut. John Smith and Midshipman Laub of the Lawrence, and Midshipman Clark of the Scorpion. Commodore Perry bestowed high encomiums in his official report upon his officers and men generally, particularizing Capt. Elliott, Lieuts. Yarrington, Smith, Edwards, Turner, and Packett; Surgeon Brevoort of the 9th infantry, who volunteered for duty as marine officer; Sailing Masters Brown and Champlin; Pursers Hambleton and Smith; Midshipmen Forrest, Laub, Clark, and Stout, Webster, and Claxton. The greatest distinction was bestowed upon the wounded officers, which was handsomely acknowledged by the enemy, and a lasting friendship sprang from this occasion between Barclay and Perry. Commodore Barclay subsequently, on a public occasion in Canada, declared that "Perry's humanity to his prisoners alone would have immortalized him," and gave as a toast: "Commodore Perry, the gallant and generous enemy." The results of the action were highly important.

The American naval supremacy on the lake was completely established, and the U. S. flag, together with such of the captured

vessels as could be used for the service, coöperated efficiently with Gen. Harrison by transporting troops and stores. Detroit, which had been captured by the British, was immediately evacuated, and the whole territory of Michigan was released from the occupation of the British army and from the horrors of an Indian warfare which had prevailed there. Congress bestowed gold medals upon Perry and Elliott for their conduct in the action, and appropriate rewards upon the officers and men generally. The remains of the officers killed in the battle were buried at Put-in-bay island, and on Sept. 10, 1858, the corner stone of a monument in commemoration of the victory, and in honor of the dead, was laid on this island with imposing ceremonies. The remains of Perry's flag ship the Lawrence and the Niagara are sunk in the N. side of the bay at Erie.

ERIGENA, JOHN SCOTUS, a scholastic philosopher, born near the beginning of the 9th century, in one of the British isles, history does not determine which. His name Scotus is supposed to favor the claim of Scotland to have given him birth, and Erigena that of Ireland; but the latter is the more probable, especially as Ireland was the original seat of the Scots. The same obscurity covers the last years of his life; it is probable that he died about 875, but whether in France or England is uncertain. The most learned doctor and extraordinary thinker of his time, his life is best explained by supposing him to have been educated in Ireland, where, as it is reported, a colony of philosophers had preserved almost intact, during the tumults of barbaric invasion, the traditions of the Alexandrian school of philosophy elsewhere completely lost. Some old annalists identified him with another John who died a martyr, by which confusion Erigena enjoyed, in some localities, the honor of saintship. According to a contemporary writer, Prudentius, bishop of Troyes, he was not a priest, and belonged to no religious order. He passed over to France, to the court of Charles the Bald, before 847, where he was placed at the head of the school of the palace, and where he engaged in the grave religious discussions of his time, concerning grace and the eucharist, and in sublime philosophical speculations which had been rare since the death of Proclus. The esteem in which he was held is shown by the double task which the king imposed upon him, of translating into Latin the Greek works of the pseudo Dionysius the Areopagite, and of composing a treatise against the doctrines of Godeschalco or Fulgentius about predestination. He says in one of his works that he feared neither authority nor the fury of unintelligent minds enough to make him hesitate to declare loudly what his reason made evident to him, and his writings manifested a freedom of thought and a philosophical audacity which quickly alarmed those who had invoked his aid. He affirmed the eucharist to be a remembrance or commemoration of the sacrifice upon

the cross; and in answering those who annihilated the freedom of the will, he elevated the moral nature of man to the exclusion of the efficacy of grace. His views were condemned by the councils of Valencia in 855, and of Langres in 859, and Pope Nicholas I. demanded his disgrace of Charles the Bald. From this point information concerning his career is entirely wanting, and though there are traditions of his having resided at Oxford, it is not certain that he left France, or that the king obeyed the mandate of the pope. Many of his works are lost, including the treatises *De Corpore et Sanguine Domini*, *De Visione Dei* (excepting an unimportant fragment), and *De Egressu et Regressu Animæ ad Deum*. His most important work remains, *De Divisione Naturæ*, which was first published at Oxford in 1681, and was republished in 1838, with notes by Schüter, at Münster in Germany. A complete abstract of it is given in Sharon Turner's "History of the Anglo-Saxons." It contains all his philosophy, in the form of a dialogue between master and pupil upon the universe, nature, and what is termed that grand universality of being which embraces at once God and man. The human intelligence is, according to him, inhabited by emanations from the divine intelligence; our ideas are pure theophanies, or manifestations of the Creator in his creature. He divides nature into 4 categories: 1, God, who possesses and diffuses life; 2, the first causes or eternal ideas by which he accomplishes his work; 3, the sensible world of the creation, of which man is the summit; 4, God as he shall be at last when the perfected world, its destiny being accomplished, shall return to him. He seeks with anxious enthusiasm to place the world and man in the bosom of the Deity, and to robe them with divinity. It is remarkable that, though his writings upon ecclesiastical dogmas were quickly condemned, there was no one in the 9th century either at court or in the church able to understand his philosophical views. It was not till the 13th century that the council of Paris discovered their pantheistic character, and condemned them. After the barbarous ages which followed the northern invasions, Erigena rose suddenly to the heights of metaphysics, undertook to reduce the Christian faith to a scientific system, and founded the philosophy of the middle ages. He was intimate with the ideas of Plotinus, Proclus, and the Greek fathers, and has been ranked as at once the last of the Neo-Platonists, and the first of the scholastics.

ERIOMETER (Gr. *εριον*, wool, and *μετρον*, a measure), an instrument invented by Dr. Thomas Young for determining the diameters of delicate fibres, as those of wool, and also the diameters of minute globules, as those of the blood, &c. Its principle depends upon the fact that a portion of the shadows cast by these small objects, placed in front of a strong light, assumes the form of concentric circles of the

different colors of the spectrum; the diameter of these circles being proportionate to that of the objects, and also to the distance of these from the surface upon which the circles are formed. The instrument is thus described in Brewster's "Optics": "It is formed of a piece of card or a plate of brass, having an aperture of about $\frac{1}{8}$ of an inch in diameter, in the centre of a circle about $\frac{1}{4}$ inch in diameter, and perforated with about 8 small holes. The fibres or particles to be measured are fixed in a slider; and the eriometer being placed before a strong light, and the eye assisted by a lens applied behind the small hole, the rings of colors will be seen. The slider must be then drawn out or pushed till the limit of the first red and green ring (the one selected by Dr. Young) coincides with the circle of perforations, and the index will then show on the scale the size of the particles or fibres."

ERIVAN, or **RUSSIAN ARMENIA**, a Trans-Caucasian government of Russia, divided into 7 circles, bounded N. and E. by Georgia, S. by Persia, W. by Turkish Armenia; area, about 6,000 sq. m.; pop. about 410,000, of whom 120,000 are nomadic and gypsy tribes, who are all Mohammedan, while the rest are Armenians. The principal river is the Aras or Araxes. The principal mountain is Mt. Ararat in the south. The country is rich in salt, and in gold, silver, and other minerals. Although the government is still frequently called Erivan, after its Persian name Rewan, its more recent denomination is Russian Armenia.—**ERIVAN**, the fortified capital, is situated on the Zenghi, an affluent of the Aras, 40 m. N. E. from Mt. Ararat, and 116 m. S. W. from Tiflis; pop. 15,000. It is the seat of an Armenian patriarch, who resides in a monastery in the vicinity, has a beautiful mosque, a large bazaar, a cannon foundry, and manufactories of morocco leather and of cotton fabrics. It is strongly fortified, is a station for caravans from Tiflis and Erzeroum, and has considerable trade with Turkey, Persia, and Russia. It is thought to have been founded by an Armenian king in the 1st century of our era, and formerly occupied a site nearly one mile distant from its present position, to which it was transferred in 1635. In the vicinity, on a lofty rock, is an immense oval citadel, and the remnants of ruined cities are found in the surrounding plain. In the 16th century it became the residence of the Persian kings of the Sophian dynasty. Several times besieged and captured by the Turks, it returned under Persian domination about the middle of the 18th century. The Russians were repulsed from it in 1808, but took it in 1827, and their general Paskevitch received the surname of Erivanski. It was confirmed to the Russians by treaty in the following year.

ERLACH, a district in the Swiss canton of Bern; pop. 6,570. Its chief town, of the same name, on the lake of Biemme, and on a spur of the Jolimont (pop. about 1,000), contains the castle of Erlach, the cradle of the noble Swiss family of that name. Many of its members were emi-

nent generals, and sturdy champions of the liberties of Bern.—**RUDOLPH OF ERLACH** achieved, July 21, 1339, a brilliant victory at Laupen over the count of Nydau and his allies. He was as generous as he was brave, and became the tutor and protector of his enemy's children. He was murdered in 1360 by his son-in-law, Jost von Rudens.

ERLANGEN, a town of Bavaria, in the circle of Upper Franconia, on the river Regnitz, on the railway from Bamberg to Nuremberg, and on the *Ludwigs-Kanal*; pop. 11,000. It has a famous university, opened Aug. 23, 1743, which is the only Protestant institution of the kind in Bavaria. It is attended on an average by about 500 students, and possesses faculties of theology, medicine, &c., a museum of natural history, a botanic garden, and a library of about 100,000 volumes. Erlangen is renowned among German towns for the pleasantness and cheerfulness of its appearance. It is divided into an old and new town. The latter is especially well built, and owes its origin chiefly to French Huguenots, to whom it was assigned as a residence by Margrave Christian Ernest in 1686, after the revocation of the edict of Nantes. In remembrance of this prince, the new town is frequently called Christian Erlangen. The town has manufactories of hosiery and gloves, and many breweries. A monument, designed by Schwanthaler, in honor of Margrave Frederic of Baireuth, the founder of the university, adorns the public square. There are 5 churches in the town: 2 Lutheran, 1 Dutch Reformed, 1 French Reformed, and 1 Roman Catholic. A convention of German naturalists was held here in 1840, and of German philologists and orientalis in 1851.

ERLAU (Hung. *Eger*), a town of Hungary, capital of the county of Heves, situated in a deep and charming valley, on the river Erlau, an affluent of the Theiss; pop. 18,400, chiefly Roman Catholics and Magyars. It has weekly fairs, linen and cloth manufactories, and an important trade in wine, Erlau wine being the best red wine of Hungary. There are 2 warm springs here, much resorted to for diseases of the skin. The town has 4 suburbs and many stately public buildings. The cathedral, the episcopal palace, several churches, and the hospital founded by Komáromy, are the most notable edifices; and the college (formerly the university), with library and observatory, is the principal learned institution. Erlau, important as a bishopric from the time of St. Stephen, became the seat of an archbishop in 1804. In former times, though it possessed strong fortifications, it suffered much from the Tartar and Turkish invasions, especially in 1552, when it repulsed under the heroic Stephen Dobó the repeated assaults of an immense Turkish army, and in 1596, when it was given up to the Turks by the foreign part of the Austrian garrison. Among the remnants of the old fortress the tomb of Dobó is still shown to visitors. Erlau was conspicuous during the revolution of 1848—

'49 for the patriotic spirit of its inhabitants, and as the place whence both Dembinski and Görgey started for their chief campaigns against the Austrians under Windischgrätz.

ERMAN, **PARTL**, a professor of physical science at Berlin, born in 1764, died Oct. 11, 1851, officiated first at the French gymnasium in Berlin, then in the military school, and, when the university was established, at the latter institution until his death. His contributions to science embrace a wide range of subjects, and more especially magnetism and electricity. Having been for some time the academical secretary for the physical sciences, he became on the reorganization of the academy joint secretary, with the celebrated astronomer Encke, of both the physical and the mathematical class. The galvanic prize instituted by Napoleon I. was awarded to him by the French academy of sciences in 1806.—**GEORG ADOLF**, son of the preceding, born in Berlin in 1806, pursued at the university the study of natural history, which he afterward continued at Königsberg under the instruction of Bessel, whom he accompanied to Munich on a scientific journey. Between 1828 and 1830 he performed at his own expense a journey round the world, chiefly with the object of making a series of magnetic observations. Hansteen, who had been sent by the Swedish government on a similar expedition to western Siberia, was his fellow traveller as far as Irkootsk. Here the two savants parted company, Erman proceeding alone to Kamtchatka, whence he sailed to the Russian colonies in America, and, by way of California, Tahiti, Cape Horn, and Rio Janeiro, returned to St. Petersburg and Berlin. A description of his journey is embodied in his *Reise um die Erde, durch Nord-Asien und die beiden Oceane in den Jahren 1828, '29, und '30 ausgeführt, in einer historischen und einer physikalischen Abtheilung dargestellt* (5 vols. 8vo., Berlin, 1833-'48). An English translation of a portion of his travels, by W. D. Cooley, entitled "Travels in Siberia, including Excursions Northward down the Obi to the Polar Circle, and Southward to the Chinese Frontier," appeared in London, in 1848 (2 vols. 8vo.). He has also published separate works on the courses of the river Obi and on the animals and plants collected by him on his journey, and has contributed largely to Poggendorff's *Annalen* and other scientific periodicals. Since 1841 he has edited the *Archiv für wissenschaftliche Kunde von Russland*, which is exclusively devoted to new scientific researches, connected with the geography, ethnology, and geology of Russia. Many Russian savants coöperate with Erman in this publication, which is one of the best authorities on the subjects of which it treats. He is now (1859) professor of physical science at the university of Berlin.

ERMINE, a name given to several weasels, of the genus *putorius* (Cuv.), inhabiting the northern parts of both hemispheres, and which in the winter season exchange their brown color for a white livery more or less pure. The

European ermine (*P. erminea*, Linn.) is about 10 inches long, with the tail half the length of the body; in the summer season it is reddish brown above, whitish below, with the tip of the tail black; in this livery it is called the stoat in Great Britain. In the winter, however, the upper parts become white, with a yellow tint beneath, the tip of the tail remaining black at all seasons; in this color the fur was formerly highly prized, especially for ornamenting garments pertaining to royalty and offices of dignity; for the purity of its whiteness it was taken as the emblem of the incorruptibility and the integrity which should characterize a judge. This animal is widely distributed in northern Europe and Asia, extending its range even to the highest latitudes visited by man. Its habits are sanguinary, like those of all of its genus, though from its smaller size it does less mischief in the farm yard than the polecat; it attacks and kills rats, mice, moles, and young poultry, sucking their blood; it often domesticates itself in houses, where its destruction of rats and mice in part compensates for its damage to the farmer in the hen house. There are at least 5 North American weasels entitled to the name of ermine; but it is very improbable that the *P. erminea* is found upon this continent. The animal called ermine by Audubon and Bachman, and considered by them the same as the European animal, was first described as a distinct species by Dekay as *P. Noveboracensis*. The color in summer is chestnut brown above, whitish below and on the inner surface of the limbs; edge of upper lip white, and end of tail black; in winter, in northern latitudes, the hairs are snowy white from the roots, except on the end of the tail, which is black for about $1\frac{1}{2}$ inches; south of Pennsylvania the change to white does not take place, the color remaining brown throughout the year. The head is depressed and acute; the ears are large and extend far round the meatus; the body is elongated, and the tail cylindrical, thickly clothed with fur about $1\frac{1}{2}$ inches long at the end; the limbs are short and stout; there are 5 toes on each foot, the inner the shortest, all covered with fur, which hides the naked pads on the soles; on each side of the under surface of the tail are glands which secrete an offensive musky fluid. The fur is short, but very soft. The length to root of tail is $10\frac{1}{2}$ to 11 inches; length of tail to end of hair $6\frac{1}{2}$ to 7 inches, the bones extending about $5\frac{1}{2}$ inches. It is a graceful, quick, and fearless animal, living under logs and heaps of stones, and in holes in rocks. It destroys rabbits, partridges, and domestic fowls much larger than itself; satiated with the blood of a single victim, it kills all within its reach from an instinctive propensity to kill; it has been known to destroy 40 fowls in a single night; from its vermiform body it is able to pursue hares into their burrows and the field mice into their galleries. Though occasionally destructive to poultry and eggs, it is much more a benefactor to the agriculturist by killing the mice which de-

vour his grain, potatoes, and grasses; it will soon rid a granary of the largest rats, and a field of the wheat-loving ground squirrels. It is not shy, and has been so far domesticated as to be employed like the ferret of Europe in hunting hares; it is easily taken in any kind of trap. It is not common anywhere; it prefers stony regions, and is solitary and nocturnal in its habits, though occasionally seen at all hours of the day. It is a poor swimmer and avoids water, and rarely ascends trees except when pursued. The young, from 4 to 7 in number, are born between the last of March and the last of May, according to latitude. The coat is shed twice a year, in October and March, the autumn fur becoming white, and the spring brown. According to Mr. Baird, this species cannot be certainly traced N. of Massachusetts nor W. of Wisconsin; it has been taken at Fort Smith, Ark., and probably is found in most of the southern and southwestern states at a distance from the sea coast. The most striking differences between this and the European ermine are, that in the latter the caudal vertebræ are only $\frac{1}{2}$ the length of the head and body, the terminal hairs being nearly $\frac{1}{2}$ their length, or from $1\frac{1}{2}$ to $2\frac{1}{2}$ inches; while in the former these vertebræ are nearly $\frac{1}{2}$ the length of the body, the hairs being only about $\frac{1}{2}$ of their length, or not more than $1\frac{1}{2}$ inches; in our species the ears and naked portion of the nose are larger; the coloration also differs in the much greater extension of the light colors on the lower parts and inside of the limbs in the European animal, and in the greater comparative extent of the black tip to the tail: there are 4 sacral and 21 caudal vertebræ in our ermine, and only 3 of the former and 19 of the latter in the European. The little ermine (*P. Richardsonii*, Bonap., or *P. agilis*, Aud. and Bach.), which replaces the preceding species north of Massachusetts, is from 8 to 9 inches long, exclusive of the tail, which is slightly more than 5; the color in summer is dark chestnut brown above and whitish below, with the whole upper jaw brown, and the end of tail black $\frac{1}{2}$ to nearly $\frac{1}{2}$ of its length; in winter white with a black-tipped tail. It is smaller and darker, with more slender and delicate feet than the preceding species; its geographical distribution is from 65° N. to Massachusetts on the E. and Vancouver's island on the W. coast. The long-tailed ermine (*P. longicauda*, Rich.) approaches the ferrets in size, being about 11 inches long exclusive of the tail, which is 6 to 7 inches; the color in summer is light olivaceous brown above, and brownish yellow below, with the chin and edge of upper lip white; in winter white, with a black-tipped tail; the muzzle is broad, the hair short, coarse, and stiff, and the ears low and short; the feet are large, with well developed claws. It is found about the upper Missouri and Platte rivers. The least ermine (*P. cicognanii*, Bonap., or *P. fuscus*, Aud. and Bach.) has an average length of 8 inches, with a tail of 3 or 4 inches; the colors are as in the other species in summer

and winter; the edge of the upper lip is white; it is found from Labrador to Massachusetts, and as far west as Puget's sound. Kane's ermine (*P. Kaneii*, Baird) is about 8½ inches long, with a tail of 4 inches; it seems a miniature of the European species, and is found in Siberia and the vicinity of Behring's straits.

ERNEST AUGUSTUS, king of Hanover, 5th son of George III. of England, born Jan. 5, 1771, died Nov. 18, 1851. He was for many years a member of the British house of lords as duke of Cumberland, and was a field marshal in the British army. Against the desire of his mother he married, in 1815, Frederica Caroline of Mecklenburg-Strelitz, whose first 2 husbands, Prince Louis of Prussia and the prince of Solms-Braunfels, had both died. The grant which he asked from parliament on occasion of his marriage not being accorded to him, he took up his residence in Germany, but returned to England in 1829 to vote against the Catholic emancipation bill, although it was proposed by his former political friend, the duke of Wellington. His conduct on this occasion was severely censured by his brother the duke of Clarence, afterward William IV. He again applied to parliament for money, for the education of his son (George Frederic, the present king of Hanover), but as it was only granted under condition that the young prince should be instructed in England and in the spirit of English institutions, he was compelled to remove his family from Germany. Grave imputations upon his private character, and his unbending opposition to all popular reforms, combined to make his residence in England as disagreeable to himself as it was hateful to the people. On the death of William IV. (June 20, 1837), the crown of Great Britain devolved on Queen Victoria, and the succession to the throne of Hanover being limited to the male line, the two countries were separated, and the duke of Cumberland, eldest surviving brother of William, ascended the throne of Hanover under the name of Ernest Augustus. Here he became notorious for his tyrannical disposition. His first act was to abrogate the constitution of 1833, which had been sanctioned by William IV. In 1848 he yielded for a time to the exigencies of the moment, and granted a more liberal constitution. Shortly before his death, he concluded a treaty with Prussia, by which Hanover joined the German *Zollverein* (Sept. 7, 1851). He was succeeded by his son, Georg V. (born May 27, 1819), the present king of Hanover.

ERNEST I., duke of Saxe-Coburg-Gotha, born Jan. 2, 1784, died Jan. 29, 1844, succeeded his father, Duke Francis, on the throne of Coburg as Ernest III., Dec. 9, 1806. He was successively connected with the Prussian and Austrian armies, in the war against Napoleon, during which his duchy was for some time in the possession of the French. In reward for his services against Napoleon, territory comprising a population of about 25,000 was added to his duchy, including the principality of Lichten-

berg, which he sold in 1834 to Prussia for 2,000,000 thalers. He invested this amount in the acquisition of various domains; and by the extinction of the Gotha line of dukes in 1826, he became duke of Gotha, and thus the first duke under whose sceptre Gotha and Coburg were united. He was an enlightened prince, a zealous patron of science and letters, and endowed his country, and especially his capital, with many beautiful structures and valuable institutions. He was the father of Prince Albert, consort of Queen Victoria.—ERNEST II. of Saxe-Coburg-Gotha (or Ernest IV. of Saxe-Coburg), son of the preceding, born June 21, 1818, married in 1842 a daughter of the grand duke of Baden. He gave to his people a new and more liberal constitution, fought against Denmark in 1849, and is distinguished for his literary and musical attainments and for his conciliatory disposition in politics. He has composed several operas.

ERNESTI, JOHANN AUGUST, a German philologist, born in Tennstädt, Thuringia, Aug. 4, 1707, died in Leipsic, Sept. 11, 1781. His critical editions of Greek and Roman classics, Xenophon, Homer, Callimachus, Polybius, Suetonius, Tacitus, and Cicero, are justly celebrated to this day, especially the edition of Cicero's writings, and the glossary appended thereto, *Clavis Ciceroniana* (6th ed., Halle, 1831). His excellent Latin style obtained for him the surname of the German Cicero. As a theological writer he belonged to the school of rationalists. His most distinguished theological work is his *Institutio Interpretis Novi Testamenti* (3d ed. 1775), of which an English translation, by C. H. Terrot, appeared in Edinburgh (2 vols. 12mo., 1833-'43).—His nephew, AUGUST WILHELM (1733-1801), edited the works of Livy (1769) and Ammianus Marcellinus (1773), beside many others.

ERNST, HEINRICH WILHELM, a German violinist, born in Brünn, Moravia, in 1814. He studied in the musical conservatory of Vienna, where Mayseder and Paganini befriended and instructed him, and subsequent to 1831 in that of Paris. From being known chiefly as a performer at chamber concerts in the latter city, he gradually extended his reputation over Europe, where he has for many years ranked among the first living violinists. As a composer for the violin he has produced the "Elegy," a "Carnival of Venice," and other successful pieces.

EROS, in Greek mythology, the god of love, first mentioned by Hesiod. He was the impersonation of the elemental principle of love, the first god who sprang into being from the world's egg, harmonizing the discordant elements of the universe and binding human kind together in sympathy. The Eros of the later poets, very different from the cosmogonic Eros, was a wanton and handsome youth, the son of Aphrodite and Zeus, and the inspirer of violent sensual passion. He is the Cupid of the Latin poets. (See CUPID.)

EROSTRATUS, or HEROSTRATUS, an Ephesian who lived in the middle of the 4th century B. C., and whom a deed of infamy has entitled to

a place in history. On the night in which Alexander the Great was born, in the year 356 B. C., he set fire to the temple of Artemis at Ephesus, which was speedily burned. When it was ascertained who had perpetrated the sacrilege, the incendiary was arrested and put to the torture. Being asked what had prompted him to the commission of such an act, he replied: "A yearning for immortality," whereon the Ephesians passed a decree consigning his name to oblivion; but this ordinance proved a vain measure, for Theopompus secured to the criminal the object of his aspiration, by making mention of him in his history.

ERPENIUS, or VAN ERPEN, THOMAS, a Dutch orientalist, born in Gorkum, Sept. 7, 1584, died in Leyden, Nov. 18, 1624. He was educated at the university of Leyden, travelled in England, France, Germany, and Italy, and perfected himself at Paris and Venice in Arabic, Turkish, Persian, and Ethiopic. In 1612 he returned to Holland, was appointed oriental professor at the university of Leyden, and established a press in his own house for the printing of Arabic works. He was subsequently appointed oriental interpreter to the Dutch government, in which capacity he had not only to translate, but also to reply to the various despatches of the Asiatic and African princes, which the extent of the Dutch commerce at that time rendered very numerous. He wrote many important works, especially on subjects connected with the Arabic.

ERRARD, CHARLES, a French painter and architect, born in Nantes in 1606, died in Rome, May 15, 1689. He was instructed in painting by his father, and perfected his knowledge at Rome. On his return to France he gradually rose to eminence in his profession. In 1648 he became one of the 12 founders of the academy of painting. He was engaged in the decoration of the *Palais royal*, Louvre, and other palaces. His chief claim to notice rests, however, upon his connection with the foundation of the French academy at Rome, which was projected by him and carried into effect in 1666, with 12 pupils.

ERSCH, JOHANN SAMUEL, a German cyclopædist, born in Grossglogau, Prussian Silesia, June 23, 1766, died in Halle, Jan. 16, 1828. He attended in his youth the university of the latter town and that of Jena, and was afterward connected in Halle with Meusel's learned periodical, *Das gelehrte Deutschland*, and in Jena with a political journal. He published a voluminous collection of the documents found in German political, geographical, and scientific periodicals (*Repertorium über die allgemeinen deutschen Journale und andere periodische Sammlungen für Erdbeschreibung, Geschichte, und die damit verwandten Wissenschaften*, 3 vols. 1790-'92). The appearance of this work created a great sensation among German bibliographers. His efforts were so much encouraged by Hufeland and other prominent savants, that he was induced to undertake a digest of literature

in connection with a general literary gazette. This work is singularly characteristic of German elaborateness. No fewer than 8 volumes (*Allgemeines Repertorium der Literatur*, Jena and Weimar, 1793-1809) were required to epitomize the literary productions of 15 years (1785-1800). It should, however, be borne in mind that not only books, but also newspaper and magazine articles, were recorded in this publication; and one of the most extraordinary features of it was, that even the criticisms to which the respective literary productions had been subjected were referred to with the utmost precision, different marks being used to designate the adverse or favorable character of the comment. While this was in progress, he projected a universal cyclopædia of modern literature, which he carried out so far as to publish 5 volumes on French literature, *Das gelehrte Frankreich*, and also an edition of the same in French under the title of *La France Littéraire* (1797-1806). He was also engaged during the same period in various editorial labors. In 1803 he was invited to fill the chair of geography and statistics at the university of Halle, and from 1808 to the time of his death he acted at the same time as chief director of the university library. He crowned the labors of his life by establishing in conjunction with Gruber *Die allgemeine Encyclopädie der Wissenschaften und Künste*, the 1st section comprising from A to G, of which 17 volumes (the first appearing in Leipzig in 1818) were edited by Ersch and Gruber. After Ersch's death that section was continued by Gruber, and on his death in 1851 by M. H. F. Meier and Hermann Brockhaus. The 2d section, to comprise the letters H to N, is under the editorial care of A. G. Hoffman of Jena, and the 3d and last section, from N to Z, under that of M. H. F. Meier of Halle. The total number of volumes published in June, 1859, was 125. This is the most learned and elaborate German cyclopædia extant, and the greatest literary achievement in Germany of the present century. A 3d edition of his *Handbuch der deutschen Literatur seit der Mitte des 18-ten Jahrhunderts bis auf die neueste Zeit* (2 vols., Amsterdam and Leipzig, 1812-'14; new and enlarged ed., Leipzig, 1822-'28) was prepared by Geissler, who added to it a cyclopædia of philology in 1845 and of philosophical literature in 1850 (*Bibliographisches Handbuch der philosophischen Literatur der Deutschen von der Mitte des 18-ten Jahrhunderts bis auf die neueste Zeit*, Leipzig, 1850, 8vo.). Thus the first foundation for a thorough modern German system of bibliography was laid by Ersch's indefatigable industry, while his enthusiasm for cyclopædias has enriched the world with imperishable storehouses of information.

ERSE, or EARSE (*Hersish*), the language of the Gael in the highlands of Scotland, they being supposed to be an Irish (Erse) colony. *Gaelic Albanach* is the name given to it by the highlanders themselves, who were driven northward by the Cymri, and hence were called Scots (*scuits*, fugitives). This language, the

Manx of the isle of Man, and the Erinakh or Irish of Ireland, constitute one branch of the Celtic or Gallic family; the other branch consisting of the Cymric of Wales, the now extinct Cornish, and the Breizad (*Bas-Breton*) in France. The term Erse has also been erroneously applied to the Scandinavians, and especially to their language. Grant (1844) attempted to derive the Gaelic from the Pelasgic. R. A. Armstrong proves it to be nearer to the ancient Celtic than is the Welsh or the Irish, and that it has fewer inflections. Dr. Prichard and A. Pictet have shown the Celtic tongues to be of the Indo-European class. The Gaelic was not written till after the arrival of the Romans in Great Britain. No ancient inscriptions or manuscripts in it have yet been discovered. Its so called Irish alphabet consists of 18 letters, nearly of Anglo-Saxon shape, named from trees (*ailm*, elm; *beithe*, birch; *coll*, hazel, &c.). The letters *k*, *q*, *v*, *x*, *y*, and *z* are wanting. Many consonants are not pronounced. The pronunciation varies in different periods and localities. Dr. Stewart, who translated the Scriptures, and Dr. Smith, who made a metrical version of the Psalms, both settled the orthography. The indefinite article, the neuter gender, and a special form for the present tense of the verbs, are wanting in Gaelic. There are 2 declensions and 2 conjugations. A peculiar metaphony is much used, as: *fear*, a man; *fir*, of a man; *fhir*, O man! The system of prefixes and suffixes resembles that of the Semitic tongues. The numerals are: *aon*, a *h-aon*, 1; *dha*, a *dha*, 2; *tri*, 3; *ceithir*, 4; *cuig*, *coig*, 5; *sè*, *sia*, 6; *seachd*, 7; *ochd*, 8; *naoi*, *naoth*, 9; *deich*, 10; *aon deug*, 11, &c.; *fhichead*, 20; *deich ar fhichead*, 30 (10+20); *da fhichead*, 40 (2×20), &c.; *ceud*, *ciad*, 1,000, &c. The nominative plural is formed by adding *ean*, as *clàr sair-ean*, harpers. The sexes are distinguished by 3 methods: by different words, by prefixing *ban* or *bain* for feminines, and by an adjective. The personal pronouns are: *mi*, *mhi*, I; *tu*, *thu*, thou; *e*, *se*, he; *i*, *si*, she; *sinn*, we; *sibh*, you; *iad*, *siad*, they. The relative pronouns are: *a*, who, which; *an*, whose, and to whom; *na*, that which; *nach*, who not. The possessives are: *mo*, my; *do*, thy; *a*, his, her; *ar*, our; *dhur*, *ur*, your; *anjam*, their. The interrogatives are: *co*, who; *cia*, which; *ciod*, what. The indefinite pronouns are: *cach*, the rest; *cuid*, some; *eile*, other. Among the verbs are: *phaisg mi*, I wrapped; *phaisg thu*, *phaisg e*, &c.; negatively, *do phaisg mi*, &c. *Abair*, to say; *thubhairt mi*, I have said; *air radh*, said; *ag radh*, saying. Verb to be: *ta mi*, I am; *ta thu*, thou art; *ta e*, he is; *ta sinn*, we are, &c.; *am bheil mi*, am I; *cha'n eil mi*, I am not, &c. Among the prepositions are: *a*, *as*, of; *ag*, at; *air*, on; *an*, in; *bhàrr*, off; *car*, during; *do*, to, of; *eadar*, between; *gu*, till; *mar*, as, like; *o*, from; *ré*, during; *re*, *ri*, *ris*, to; *trid*, through, &c. The language is very guttural, and its euphonic methods peculiar. The following is a specimen from Ossian:

FIONNGHAL. DUAN I.
FINGAL. SONG I.

Shuidh Cuchullin aig balla Thùra,
Sat Cuchullin by (the) wall (of) Thura,
Fo dhùbhra craobh dhuille na fuaim;
In (the) shade (of a) tree foliage whose sounded;
Dh'aom a shleagh ri carraig nan còra,
Leaned his spear against rock (crag) of caves,
A sgaith mhòr r'a thaobh air an fheur.
His shield huge by his side on the grass.

—The principal work in Gaelic is the poems of Ossian in the original, translated into English by Macpherson, and into Latin by R. Macfarlan (3 vols., London, 1807). There are also other lyric and epic poems, military and funeral songs of the bards; the best being of the times just before and after the Christian era. There are Gaelic and English dictionaries by William Shaw (London, 1780), P. Macfarlane (Edinburgh, 1815), R. A. Armstrong (London, 1825), the highland society (Edinburgh, 1828), Norman McLeod and Daniel Dewar (London, 1845). Some of these have grammars with them.

ERSKINE, EBENEZER, a Scotch theologian, founder of the Secession church of Scotland, born June 22, 1680, died in Stirling, June 22, 1756. The son of a Presbyterian divine, he was educated at the university of Edinburgh, licensed to preach in 1702, became pastor the next year in Portmoak, and held that post 28 years. Here and at Stirling, where he lived from 1731 until his death, he was a great favorite with his parishioners, as well as with the church throughout Scotland. The dissensions in the church of Scotland began in 1720, when the book entitled the "Marrow of Modern Divinity" was thought to reveal latitudinarian tendencies dangerous to the prevalent doctrines. Refusing to take the abjuration oath, and opposing the reimposition of lay patronages, as contrary to the act of union and to the liberties of the Scottish church, and at the same time being one of the most influential defenders of what were termed the "Marrow" doctrines, Mr. Erskine was proclaimed in many polemical pamphlets an innovator in religion and a troubler in Israel, was censured by the synod, and in 1733 was solemnly rebuked and admonished at the bar of the general assembly. Against this decision, he with 3 other clergymen entered a protest; and as they continued the conduct for which they had been censured, they were suspended from their functions. This sentence was soon after removed, but the deposed brethren had meantime formed themselves into a separate consistory and received numerous accessions. Erskine continued to preach to large congregations at Stirling till his death.

ERSKINE, THOMAS, baron, a British jurist and statesman, the 3d son of Henry David, 10th earl of Buchan, born in Edinburgh, Jan. 21, 1750, died at Almondell, near Edinburgh, Nov. 17, 1823. Having studied at the high school of Edinburgh and attended for a while the classes of mathematics and natural philosophy at the university of St. Andrew's, though he was never matriculated at that institution, he gratified his

predilection for naval life by entering the service as midshipman. Disappointed in his hope of promotion, he quitted the navy for a commission in the army. In 1770, soon after his marriage, he went with his regiment to Minorca, where he remained 2 years. Returning then to London, he became known in society as a young officer of extraordinary conversational powers. After 6 years of military service, during most of which time he was stationed in English country towns, he was induced to turn his thoughts to the law; his mother, a woman of great gifts of mind, approved his inclination, and in 1777 he entered himself a fellow commoner of Trinity college, Cambridge, merely to obtain a degree which would shorten his passage to the bar, at the same time becoming a student at law of Lincoln's inn. In order to master the technical part of his profession, he performed the laborious duties of clerk in the office of an eminent pleader, but a ludicrous parody of Gray's "Bard" which he published in the "Monthly Magazine" proves that he found time to indulge his wit and fancy. Many of his evenings were passed in a debating association, where, after the example of Pitt and Burke, he trained his talents to that surpassing strength which afterward gained him the reputation of the first of English advocates. He also at this time studied a few of the greatest models of oratory till he almost knew them by heart. He was called to the bar in 1778, and at once secured a rapid success by his brilliant defence of Captain Baillie, prosecuted for libel on Lord Sandwich. In a strain of vehement invective against the earl, he was interrupted by the judge, who told him that Lord Sandwich was not formally before the court. "I know that he is not," replied the undaunted advocate, "but for that very reason I will bring him before the court." In 1779, Mr. Erskine appeared at the bar of the house of commons as counsel for a bookseller against the monopoly of the two universities in printing almanacs. The prime minister, Lord North, had introduced a bill to renew this monopoly, and though opposition to it was considered a desperate attempt, the measure was triumphantly rejected, many friends of the ministry affirming that after Mr. Erskine's speech they could not conscientiously do otherwise than vote against it. In 1781 he gained another great triumph in securing the acquittal of Lord George Gordon, impeached for treason as the head of the "no popery" rioters. His speech was as remarkable for argument as for eloquence, and was applauded by Dr. Johnson as having prevented the precedent of hanging a man for constructive treason. He received in 1783, at the suggestion of the venerable Lord Mansfield, a silk gown and the patent of precedence at the bar, and the same year was returned to parliament as member for Portsmouth. He was a supporter of Fox, and advocated that minister's famous East India bill; but his parliamentary speeches, though they have probably been underrated, disappointed the high expectations of his

friends, and are not comparable to his splendid pleas at the bar. With an enthusiasm for popular liberty, his best efforts were those in defence of the freedom of the press and the privileges of juries, and against the doctrine of constructive treason. In his defence of the dean of St. Asaph, charged with libel, he indignantly argued against the judge who refused to receive from the jury the verdict of "Guilty of publishing only." One of the most important of his speeches, and perhaps the first in oratorical talent, was that delivered in 1789 on the trial of Stockdale, who was arraigned for publishing a libel against the house of commons. Mr. Burke's articles of impeachment against Warren Hastings had been printed and sold throughout the kingdom before the commencement of the trial, and their masterly invective produced a deep and general impression upon the public mind against Mr. Hastings. To neutralize or repel this effect, a pamphlet was written, which Stockdale published, containing severe reflections upon the conduct of the managers of the impeachment. The pamphlet was deemed libellous; and in opposition to the sentiments of a whole people, and to the most mighty combination of talent that ever led a prosecution, amid what he himself describes as the "blaze of passion and of prejudice," Mr. Erskine undertook the defence of Stockdale, and established his reputation as the most consummate advocate of the age. Combining the utmost precision with the highest oratorical and rhetorical efforts, he rescued his client from the punishment which a nation seemed determined to award him. The doctrine expounded in his plea and sanctioned by the verdict became the foundation of the liberty of the press in England. In 1792 he acted as counsel to Thomas Paine, prosecuted as author of the "Rights of Man," and was therefor deprived of the office of attorney-general to the prince of Wales, which he had held for several years. Mr. Erskine was for 25 years engaged upon the most important cases in England, but his most arduous efforts were in 1794, when he gave the death-blow to the doctrine of constructive treason. Hardy, Horne Tooke, Thelwall, and several other persons, were arrested and committed to the tower on charge of political conspiracy and high treason. The trial of Hardy began Oct. 29, and the popular interest was such that a dense mob pressed around the court, and made it almost impossible for the judges to proceed to and from their carriages. The indictment stated 9 overt acts of high treason, but the trial turned almost solely on the question of treasonable intention. The proceedings continued to the 8th day, and the whole force of the bar was marshalled against the prisoner and his undaunted defender; but the ability and eloquence of Erskine gained a verdict of acquittal, and forced the highest admiration even from his opponents. Mr. Tooke was arraigned Nov. 10, and pronounced not guilty Nov. 20; his acquittal was followed by that

of Mr. Thelwall; and the government, in despair of convicting any of the supposed traitors, abandoned the other indictments. Mr. Erskine looked with favor upon the attempt at social renovation in France, and throughout the discussions upon French affairs at this period he opposed the interference of England on behalf of the Bourbons. His pamphlet entitled "A View of the Causes and Consequences of the War with France" rapidly passed through 48 editions. After the peace of Amiens he visited Paris, and was presented to Napoleon, who however passed him with the dry remark, *Vous êtes légiste?* Upon the death of Pitt in 1806, and the formation of Lord Grenville's coalition ministry, Mr. Erskine was appointed lord high chancellor, and created a peer under the title of Baron Erskine of Restormel castle. This ministry was, however, dissolved within a year, and he resigned his office before having had occasion to display all his ability in it. He passed the remainder of his life in retirement and comparative indigence, and unhappily a second time married. In 1815 he received the order of the thistle, and he took part for the last time in the house of lords in 1820 on occasion of the trial of Queen Caroline. Lord Erskine was doubtless the greatest of English advocates, and his eloquence may be compared without disadvantage to that of orators as illustrious as Pitt, Fox, Burke, and Sheridan. With an animated countenance, polished manners, great vivacity of mind, an easily modulated voice, and a character that seemed always young, he could lend himself admirably to every variety of sentiment. His sympathetic disposition made him always seek a look of applause in his listeners, and he once stopped in the midst of a harangue, whispering to a friend that he could not go on unless that "wet blanket of a face" opposite to him were removed. However completely absorbed in philosophical discussion or in the intricacies of a case, he was always alive to the emotions expressed in the faces of the jury, which he made the guide of his oratory. He has the honor of having presented to parliament the bill for the abolition of the slave trade, of having pleaded the cause of the Irish Catholics, supported propositions for the reform of the penal laws, and spoken and written in behalf of the struggling Greeks. His noblest efforts were in behalf of constitutional freedom, and during the momentous struggles of the period in which he lived there was no public man who had greater personal influence. There was a little of vanity in his character, and he often conversed with Dr. Parr, who was remarkably conceited, when most elaborate compliments were paid by each to the other. Dr. Parr on one of these occasions promised that he would write Erskine's epitaph; to which the other replied that "such an intention on the doctor's part was almost a temptation to commit suicide." He wrote a political romance entitled "Armatas, a Fragment" (published anonymously, 8vo., 2 parts, London, 1817), and a few political treatises; but

the chief foundation of his fame is his numerous speeches, which retain in print the brilliancy of thought, copiousness of imagery, elegance of diction, and much of the fervor which rendered them so successful when delivered. A collection of his speeches at the bar connected with the liberty of the press, and against constructive treason, by James Ridgeway, appeared in London in 1810-'11 (4 vols. 8vo.), followed in 1812 by a collection of his speeches at the bar on miscellaneous subjects, and in 1847 by his speeches at the bar and in parliament, with a memoir by Lord Brougham (4 vols. 8vo.).

ERWIN OF STEINBACH, the principal architect of the cathedral of Strasbourg, born at Steinbach, near Bühl, in Baden, died Jan. 17, 1318. The principal tower of the cathedral had been completed in the 7th century under the reign of Dagobert. It was partly built of wood, and was reduced to ruins by lightning and successive fires. The nave, commenced in 1015, was only completed in 1275. Erwin was then requested to furnish designs for the decoration of the interior of the church, and for the construction of two new towers and a façade upon the site of the ruins of the old tower. The work was commenced Feb. 20, 1276, and the foundation stone of the new structure was laid May 25, 1277. The architect died when the work was only half finished; it was continued by his son Johannes (died March 18, 1339), and was subsequently continued chiefly after his designs, which are still preserved at Strasbourg. His daughter Sabina assisted him in the decoration of the interior of the church; and another of his sons, Winhing (died in 1330), was also an architect of some distinction. The remains of this family of architects are interred within the cathedral.

ERYMANTHUS, in ancient geography, a river and mountain of Arcadia, in Greece. The river, according to some the modern Dimitzana, rises on the frontiers of Arcadia and Elis, and flows into the Alpheus. The mountain, situated to the east of the river, formed the western point of the northern barrier of Arcadia, and was covered with forests. It was in this mountain that Hercules chased and killed the famous wild boar.

ERYSIPELAS (Gr. *ερυω*, to draw, and *πελας*, neighboring, from its tendency to draw in the neighboring parts), ST. ANTHONY'S FIRE, or in Scotland, ROSE, an inflammation of the skin characterized by redness, swelling, and burning pain, commonly spreading from a central point, and sometimes affecting the subcutaneous cellular tissue. Idiopathic erysipelas almost invariably attacks the face; frequently it is preceded by loss of appetite, languor, headache, chilliness, and frequency of pulse; a spot now makes its appearance, commonly on one side of the nose, of a deep red color, swollen, firm, and shining, and is the seat of a burning, tingling pain. The disease gradually extends, often until the whole of the face and hairy scalp have been affected, but it is exceedingly rare

for it to pass upon the trunk. Often, while still advancing in one direction, the part originally affected is restored to its normal condition. Commonly large irregular vesicles (*phlyctenæ*) filled with serum, precisely similar to those produced by a scald, make their appearance on the inflamed skin. The pulse is frequent, there is total loss of appetite, headache, prostration, restlessness, and sleeplessness, and commonly, particularly at night, more or less delirium is present. The complaint runs its course in about a week, and the general symptoms ordinarily abate somewhat before any decline is noticed in the local inflammation. In itself erysipelas of the face is ordinarily unattended with danger; but where it occurs in the course of other and exhausting diseases, it adds much to the gravity of the prognosis. In fatal cases the delirium is apt gradually to lapse into coma. Erysipelas is subject to epidemic influences; in certain seasons it is exceedingly prevalent, while in others it is rarely seen. The attack is favored by overcrowding and deficient ventilation. Hospitals, particularly in the spring of the year, are infested with it. The writer recollects a crowded ward in the basement of Bellevue hospital (New York), in which for several weeks every patient that was placed in it underwent an attack of erysipelas, and many were affected a second time. Certain unhealthy states of the system predispose strongly to the disease, and an unwholesome diet and the abuse of alcoholic stimulants are commonly cited among its causes. We have seen that simple erysipelas is rarely fatal; consequently recoveries are common under a great variety of treatment. Usually it requires nothing more than to move the bowels by a mild laxative, and afterward to support the system by the administration of nutriment, and if necessary the use of quinine and wine whey. Where there is great prostration, stimulants may be freely administered; lately it has been proposed to treat all cases by the administration of the tincture of the muriate of iron in doses of from 10 to 20 drops every 2 hours, and this method has been found eminently successful. A great variety of external applications have at different times been recommended—the use of blisters applied to the centre of the inflamed part, of an epithem of mercurial ointment, the application of nitrate of silver and of tincture of iodine, &c. A simple wash of lead and opium, applied by means of linen cloths saturated with it, is commonly grateful to the patient, and answers every purpose. Systematic writers make a separate variety of the erysipelas of new-born children; it presents no peculiarity, however, except its greater gravity, in common with other diseases, in such delicate organisms. When erysipelas of the abdomen occurs in new-born children, it commonly has its point of origin in the recently divided umbilical cord. In some cases erysipelas, arising generally from some injury or excoriation, shows a tendency to advance in one direction while it passes away in

another (*erysipelas ambulans*); in this manner it may pass in turn over almost every part of the surface.—In phlegmonous erysipelas the precursory symptoms are more constant and severe, the pain more violent, the prostration greater; the redness is most strongly marked along the trunks of the lymphatic vessels, and the lymphatic glands are swollen; the swelling of the skin is more considerable, it soon assumes a pasty consistence, and pits strongly on pressure. As the disease advances, the pain subsides, the redness is diminished, and fluctuation becomes evident; if left to itself, the skin, gradually thinned and distended, sloughs over a larger or smaller space, and pus mingled with shreds of dead cellular tissue is discharged. The disease indeed seems often to be in the cellular tissue rather than in the skin, and sometimes the cellular tissue throughout a limb appears to be affected. It is a disease of great severity, and when extensive often proves fatal under the best treatment. In its treatment, the same general principles apply as in simple erysipelas. The patient's strength should be supported by a nutritious diet, and tonics and stimulants must often be freely administered. The muriated tincture of iron may here also be resorted to with great advantage. Early in the disease the skin should be freely divided down into the cellular tissue, to relieve the constriction of the parts and afford an early opening to the discharges.

ERYTHEMA (Gr. *ερυθαίνω*, to redden), an affection of the skin characterized by a slight redness without determinate form. It is generally due to the action of some special cause, as the heat of the sun, &c. Where it is produced by the friction of two contiguous surfaces, as frequently occurs in infants and in fleshy persons, it is often called *intertrigo*. *Erythema nodosum*, the severest form of the disease, is characterized by the eruption of numerous red spots from $\frac{1}{4}$ of an inch to an inch in their longest (vertical) diameter. These spots are slightly elevated; after a few days their color deepens, and passing through various shades of blue and yellow, the skin resumes its normal color. The affection is apt to be attended with fever, depression of strength, and derangement of the digestive organs. Simple erythema needs no treatment beyond the employment of soothing applications; in intertrigo, the use of an absorbent powder, as lycopodium, starch, &c., may be advisable. *Erythema nodosum* is best treated by diet, rest, and a mild laxative; in some cases tonics and iron may be used with advantage.

ERYTHRÆ, an Ionian city of Asia Minor, on the sea-coast at the extremity of a small peninsula. It had a fine harbor, in front of which were 4 small isles, called Hippi, and it was a scheme of Alexander the Great to isolate it together with the adjacent mountain of Mimas from the mainland by means of a canal. It was famed for its sibyl or prophetic woman. Its site is occupied by the modern village of Ritri, where there are many ruins of the old city.

ERYTHRÆAN SEA (Gr. *ερυθρὰ θάλασσα*, *erythrâ thalassa*,

red, ruddy), in ancient geography, originally the name of the whole expanse of sea between Africa on the S. W., Arabia on the N. W., Gedrosia on the N., and India on the N. E., including the two great gulfs, the Arabian and the Persian. In this wider sense the term seems to have been used by Herodotus, who designates by it both the Indian ocean, of the shape of which he was ignorant, and the Persian gulf, distinguishing however the Red sea, the *yam suf* or weedy sea of the Hebrews, which he calls the Arabian gulf. The term ἡ νοτιη θαλασσα (southern sea) appears in some passages of the same historian as identical with the Erythræan, in others as designating the more distant and less known region of the latter. Later and better informed geographers, distinguishing the separate parts of the sea, applied to its main body the name of Indian ocean, and to its great gulfs the names of Persian and Arabian, while the term Erythræan sea (Lat. *Mare Rubrum*) was variously used by different writers until it became confined to the Arabian gulf. The origin of the name is doubtful; it is, however, probable that it is derived from the Phœnicians (or red race; Gr. φοινίξ and φοινίκος, red), who, according to Herodotus in the opening of his work, "formerly dwelt on the shores of the Erythræan sea, whence they migrated to the Mediterranean," a statement confirmed by the critical researches of Rawlinson and others.

ERYX, an ancient town of Sicily, occupying the side of a mountain of the same name (now Monte S. Giuliano), on the N. W. coast of the island, near the promontory of Drepanum. Above it was a temple of Venus on the summit of the mountain. It early became a dependency of Carthage, was for a short time under the sway of Syracuse, was captured by Pyrrhus in 278 B. C., again reverted to the Carthaginians, and in the 1st Punic war was partially destroyed by Hamilcar, who converted it into a fortified camp, removing the inhabitants to Drepanum. A few years later it was taken by the Romans, but the city was subsequently surprised by Hamilcar Barca, and made his head-quarters till the conclusion of the war, while the Romans continued to hold the temple as an impregnable fortress. The site of the ancient city is now occupied only by a convent, and that of the temple by a Saracenic castle, now a prison, surrounded by the town of San Giuliano.

ERZBERG (Ger., ore mountain), a mining district in the circle of Bruck, Styria, so called from a mountain of the same name which for upward of 1,000 years has yielded vast quantities of iron. About 300,000 cwt. of ore of the best quality are annually extracted from these mines, and indeed the mountain might almost be called a solid block of carbonate of iron. In 1823 a colossal iron cross, 25 feet in height, was erected on its summit by the archduke John.

ERZGEBIRGE (Ger., ore mountains), a range of mountains on the boundary between Bohemia and Saxony, and in its southern portion lying chiefly in Bohemia. It extends E. N. E.,

W. S. W., about 100 m., and covers an average breadth of about 30 m. At its western extremity it connects with the range called the Fichtelgebirge, where the White Elster has its source. The river Elbe defines its E. extremity, flowing toward the N. through the valley that separates the Erzgebirge from the Winterberg. On the N. the range slopes gently toward the plains of Germany, but on the S. the descent is more precipitous, with deep and narrow valleys running down to the valley of the river Eger, which flows E. to the Elbe. The highest elevations are W. of the central part of the range. Here are the summits of Keilberg, 4,212 feet above the sea; Fichtelberg, 3,968; Schwarzwald, 3,988; and Auersberg, 3,248. These are granitic peaks, but toward the Elbe, where the granitic rocks give place to sandstone, the elevation declines to a maximum of 1,824 feet. The range is traversed by 6 great roads, the most important of them connecting Prague with Dresden and Chemnitz. The valley of the Elbe admits the passage of the range by the railroad which runs from Dresden to Vienna. The Erzgebirge have long been famous for their mineral productions. Of these the most important are silver and tin, the annual product of the former metal amounting to about 720,000 oz., and of the latter, from the mines of Saxony, to about 140 tons. Crude cobalt, called zaffre, is produced in Saxony to the amount of 400 tons, and in Bohemia 200 tons. Lead is obtained to the amount of 400 or 500 tons, iron from 3,500 to 4,000 tons, and copper about 80 tons. Other mineral products are gold, found in small quantity, mercury, arsenic, bismuth, antimony, zinc, manganese, and sulphur. Coal is found in the lower country near Dresden and Zwickau, and porcelain clay at Aue, 12 m. S. E. from Zwickau. This is used at the royal manufactory at Meissen.

ERZROUM, a province or eyalet of Asiatic Turkey, comprising the greater part of Turkish Armenia, and bounded N. by Trebizond, E. by Persia and the Russian dominions, S. by Kooristan, and W. by Seewas; pop. differently estimated at 110,000 and 600,000. It consists mainly of lofty table-land, the elevation of which is estimated at 6,000 feet, traversed E. and W. by several ranges of mountains, between which lie rich and extensive valleys. Cultivation is here well attended to, and the soil produces a profusion of excellent fruits, rye, barley, and flax, and furnishes pasturage for large herds of cattle. The climate in winter and spring is severe, and in summer the heat is excessive. The rivers Euphrates, Aras, Koor, and Tchoruk have their sources here. The mountains are inhabited mainly by Koords, who acknowledge at most a nominal allegiance to the sultan. —ERZROUM, the capital of the above province, and the principal city of Armenia, is situated on the Kara-su or W. branch of the Euphrates, in a beautiful plain about 6,000 feet above the level of the sea, 30 m. long and 20 m. broad; distance from its nearest seaport, Tre-

bizond, 120 m.; pop. in 1854, 40,000. A triple wall of stone which nearly surrounds the old part of the town, and a large massive citadel, encompassed by a double wall, and having 4 stout gates covered with plates of iron, are its principal defences. The citadel, however, is commanded by a hill in the neighborhood. The streets are narrow and filthy; the houses are mostly of wood, mud, or bricks dried in the sun; and the whole city is infested with savage-looking dogs. The principal buildings are the Greek and Armenian churches, and the custom house, beside which there are about 40 mosques and numerous caravanserais. Outside of the city are 4 suburbs. The caravans travelling from Teheran to Mecca usually halt here, and an active trade is carried on with all the adjacent countries. Shawls, silk, cotton, rice, indigo, tobacco, and madder are imported from the east, and broadcloth, chintz, cutlery, &c., from the west by the Black sea. The exports are furs, gall, and live stock. Erzroum was built by the emperor Theodosius II. about A. D. 415, and named Theodosiopolis in honor of its founder. It was twice destroyed by fire and pillage, and in 1829 was taken by the Russians. Its present name is supposed to be a corruption of *Ardzroum*, the land of Rome, the Turks frequently applying the word Roum (or Rome) to any territory anciently recognized as a part of the Roman or Byzantine empire. Its position, which commands the road from Persia to Constantinople, renders it still an important military post, as it was in the time of its Byzantine masters, and also a point of great commercial interest. It is the seat of the Turkish governor-general, of the English and other foreign consuls, and the focus of the transit trade between Europe and Trebizond on the one hand and central Asia and Persia on the other. Several American missionaries reside here.

ESARHADDON, son and successor of Sennacherib, king of Assyria, reigned in the 1st half of the 7th century B. C. He is the Sarchedon of Tobit, the Asaradinus of the Canon of Ptolemy, and the Asshur-akh-iddina of the recently discovered Assyrian inscriptions. From the latter, compared with a few passages in the books of Kings (2, xix. 37), Isaiah (xxxvii. 38), Ezra (iv. 2), and Tobit (i. 21), the history of his reign may be summed up, according to George Rawlinson's "Essay on the History of Assyria," in vol. i. of his "Herodotus," as follows: He carried his arms over all Asia between the Persian gulf, the Armenian mountains, and the Mediterranean, made war on Egypt, conquered Sidon, Cilicia, the country of the Gimri or Sacæ, parts of Armenia, Media, Idumæa, and other countries. In Susiana he contended with the son of Merodach-Baladan; on another son, refugee at his court, he bestowed a territory on the coast of the Persian gulf. Esarhaddon appears to have held his court sometimes at Nineveh and sometimes at Babylon, to which latter city Manasseh, king of Judah, was led prisoner by his captains.

He peopled Samaria by colonies drawn chiefly from Babylonia. His buildings equalled in magnificence those of his predecessors. One inscription speaks of 30 temples erected by him in Assyria and Mesopotamia, "shining with silver and gold, as splendid as the sun." One of these edifices is that known as the S. W. palace at Nimroud, which, as stated by Mr. Layard, "answers in its general plan, more than any building yet discovered, to the description in the Bible of the palace of Solomon." Another was erected at Nineveh, and called the palace "of the pleasures of all the year," "a palace such as the kings his fathers who went before him had never made." In the construction of his palaces he employed Syrian, Greek, and Phœnician artists, as well as workmen furnished him by princes of Syria and Cyprus. His works seem to indicate a long and prosperous reign. He was succeeded by his son Asshur-bani-pal, or, according to Oppert, by a Tiglath-Pileser.

ESCALADE (Fr., from Lat. *scala*, a ladder), in military affairs, an attack on a fortified place by scaling the walls with ladders, without the formalities of a siege, or raising regular works to protect the men.

ESCAMBIA, a W. co. of Florida, separated from Alabama on the W. by the Perdido river, bounded E. by the Escambia, and S. by the gulf of Mexico; area 1,110 sq. m.; pop. in 1850, 4,351, of whom 1,332 were slaves. It consists mostly of a level and not very productive country, covered with extensive pine forests. In 1850 it yielded 4,950 bushels of Indian corn, 4,150 of sweet potatoes, and 10,150 lbs. of rice. There were 6 churches and 2 newspaper offices in the county, and 269 pupils attending public schools. Named from Escambia river. Capital, Pensacola.

ESCARPMENT (It. *scarpa*, slope of a wall), in geology, a steep declivity or precipice. The term is most commonly employed in fortification, in which it designates any steep slope formed to oppose the progress of the enemy. In a fortress, the scarp is the exterior slope of the wall which supports the rampart.

ESCHEAT (law Fr. *eschet*, from *échoir* or *échoir*, to fall out, or lapse), a failure in the regular descent of lands whereby the fee reverts back to the original grantor or his heirs if they can be found, and if not, then to the sovereign, who, according to the feudal tenure, was the original source of title. Such a failure may occur for the want of heirs, or of such heirs as can inherit the particular estate. This could but rarely happen as respects an absolute estate in fee, inasmuch as heirs may be sought to the remotest degree of collateral consanguinity on failure of lineal descendants; but it is not an unfrequent occurrence where the estate is limited, as in the case of a marriage settlement by which the estate is to descend to the issue of the marriage, or of an estate tail by which a limitation is made to the heirs of a man's body or other specified heirs. In these and analogous instances, upon the failure of the heirs designated, although

there may be others capable of inheriting generally, the title to the land reverts to the grantor if no other provision has been made in the deed creating the estate. The escheat in such a case is said to be *propter defectum sanguinis*. It may also occur by an obstruction of the descent *propter delictum tenentis*, that is, when there has been a conviction of felony; in which case, according to the old phraseology, there was a corruption of blood, so that the man thus convicted was deemed in law to have no heirs. A distinction was made between treason and other felonies. In the former case forfeiture to the crown intervened and prevented the escheat of the lands to the original proprietor; in the latter, the lands of the felon were intercepted by the crown for a year and a day, and then escheated to the lord of the fee. By statute 54 George III., c. 145, no attainder for felony except treason and murder is now permitted to defeat the right of the heir or other person who would by law be entitled to the estate, except during the life of the offender. By the common law bastards were not deemed to have any heirs except of their own bodies, for being without lawful parentage, they can have no collateral kindred; therefore upon the death of a person of illegitimate birth, leaving no issue and without will, his lands escheated. So in the case of a man dying intestate leaving only alien relatives; as they could not inherit, his lands would escheat. Formerly it was held that there could be no descent even to natural-born subjects, between whom and the deceased there were lineal or collateral alien ancestors through whom they would be obliged to claim; but the statute 11 and 12 William III., c. 6, provides that an intermediate alien ancestor shall not impede the descent to one otherwise capable of inheriting.—The law of escheat in the United States varies from the English in several particulars. Thus for illustration, taking it as it exists in the state of New York, to which there is a general conformity in the other states, the ultimate property to lands is deemed to be in the people; and whenever in any private ownership there is a failure of descent by want of heirs, the property escheats to the people, or, as is more commonly said, to the state. The escheated lands are to be held, however, subject to all the trusts, encumbrances, &c., that they would have been had they descended; and authority is given to the courts of the state to direct a conveyance to the parties equitably entitled thereto. Conviction of any criminal offence except treason produces no forfeiture of lands or personal property; and where the punishment is imprisonment for life, the convict is deemed civilly dead, and his heirs take by immediate descent as they would upon his natural death. In the case of outlawry for treason, there is a forfeiture of lands to the state during the life of the offender. The lands of a person dying intestate who is illegitimate do not necessarily escheat, but descend to his mother if living, or if she is dead, to the relatives on the part of the mother. As estates tail do not exist in the United States, many of the questions

which arise in England upon the failure of particular heirs do not occur here. Properly speaking, an escheat to any private individual is unknown to our law. Not only feudal incidents, but the theory upon which they were founded, have been abrogated. In respect to aliens, a statutory provision similar to what has been enacted in England, as above mentioned, removes all disability of inheriting by reason of an intervening alien ancestor. Where property is purchased by an alien, or has been otherwise acquired, as by claim of inheritance, there being no other heirs, although by operation of law it escheats to the state, yet is his title good until divested by some proceeding on the part of the state to enforce the escheat; that is to say, it is valid against all other claimants, and even against the state itself until judgment has been rendered by some court declaring the escheat.

ESCHENBACH, WOLFRAM VON, a German minnesinger, belonging to the circle of poets which near the end of the 12th and the beginning of the 13th century frequented the court of the landgrave Hermann I. of Thuringia in the castle of Wartburg. He was of noble birth, received the honor of knighthood from the count of Henneberg (Poppo VII.), fought under the banner of different lords in the civil wars of the time, gained by his songs the hospitality of many noble dwellings, and made his longest abode at the court of Eisenach, in the mountain castle of Wartburg, where the landgrave Hermann collected the most illustrious minnesingers. Thither he went in 1204, was associated with Heinrich von Veldeck, Walther von der Vogelweide, and Heinrich von Ofterdingen, and engaged with the last in 1207 in the poetical contest known as "the war of the Wartburg," which was at length concluded by the magician Klingsor, and the legends of which were collected in a wonderful poem about a century later. Eschenbach afterward sang at other courts, and died between 1219 and 1225. Some of his poems are original, and others are imitations of troubadour songs and trouvère romances. They display depth of feeling and a mastery of language, and Frederic von Schlegel has even called Eschenbach the greatest poet that Germany has produced. The first critical edition of his works was by Lachmann (Berlin, 1833). They have been adapted into modern German by San Marte (Magdeburg, 1836-'41, 2d ed. 1858), and *Parcival* and *Titurzel* by Simrock (Stuttgart, 1842; 2d ed., 1857).

ESCHENMAYER, ADOLF KARL AUGUST VON, a German philosopher, born at Neuenburg, in Würtemberg, July 4, 1768, died Nov. 17, 1852. From 1811 to 1836 he taught philosophy and medicine and afterward practical philosophy at the university of Tübingen. He produced a great variety of writings, chiefly on philosophy. His religious views are strongly tinged with mysticism, and several of his writings are directed against the theories of Hegel and against the "Life of Jesus" by Strauss. His principal work, *Religionsphilosophie*, appeared in Tübingen in 1818-'24 (3 vols. 8vo.).

ESCHSCHOLTZ, JOHANN FRIEDRICH, a German naturalist, born at Dorpat, Nov. 1, 1793, died there, May 19, 1831. He accompanied Kotzebue's expedition of discovery (1815-'18) as physician and naturalist, and became on his return professor of medicine and director of the zoological museum of the university of Dorpat, to which he presented his mineralogical collection. He also joined Kotzebue's new expedition in 1823, published an account of it at London after his return (1826), and furnished a description of 2,400 species of animals to Kotzebue's *Neue Reise um die Welt* (Weimar and St. Petersburg, 1830). A zoological map of these animals was published by him in Berlin (1829-'33). Among his other most important works is his *System der Akalephen: eine ausführliche Beschreibung aller medusenartigen Strahlthiere* (Berlin, 1829).

ESCURIAL (Sp. *Escorial*), a palace and mausoleum of the kings of Spain, situated in Escorial de Abajo, a town of 2,000 inhabitants, in a barren region 2,970 feet above the sea, on the S. E. slope of the Sierra Guadarama, in New Castile, 25 m. N. W. from Madrid. The correct title of this celebrated palace is "El real sitio de San Lorenzo el real del Escorial," so called from having been built in fulfilment of a vow made by Philip II. that he would build the most magnificent monastery in the world, if St. Lawrence would give him victory over the French in the battle of St. Quentin, 1557. St. Lawrence suffered martyrdom by being broiled on a gridiron, and by a quaint conceit of the king or his architects, the ground plan is in the form of a gridiron, with handle and bars complete. Voltaire and other French writers have claimed for a Frenchman named Louis Foix the honor of having been the architect of the Escorial. It is, however, beyond doubt that Juan Bautista de Toledo commenced it from his own plans, and on his death, in 1567, it was continued by his pupil, Juan de Herrera. The foundation was commenced on St. Lawrence's day, April 23, 1563. Twenty-one years' labor and a sum equal to \$15,000,000 were expended in completing the work. The body of the gridiron is represented by 17 ranges of buildings, crossing each other at right angles, forming a parallelogram enclosing 24 courts, with a square tower 200 feet in height flanking each of the 4 corners of the building, thus representing a gridiron reversed, the towers being the upturned feet. A wing 460 feet long represents the handle of the implement, and contains the royal apartments. The average height of the walls is 60 feet. The total length of the building is 740 feet N. and S., and 580 feet E. and W. It contains the royal palace, royal chapel, monastery with 200 cells, 2 colleges, 3 chapter houses, 3 libraries, 5 great halls, 6 dormitories, 3 hospital halls, 27 other halls, 9 refectories, 5 infirmaries, a countless number of apartments for attendants, 80 staircases, 1,110 windows looking outward and 1,578 inward, or, including outhouses, 4,000 windows in all, beside 14 gates and 86 foun-

tains. The whole edifice is built of white stone spotted with gray, resembling granite, and quarried on the site. The Doric is the prevailing order of architecture. The most striking feature of the edifice is the church, built in general imitation of St. Peter's at Rome, in the form of a Greek cross with a cupola and two towers. It contains 40 chapels with their altars, and is 374 feet long, 230 broad, divided into 7 aisles, paved with black marble and roofed by the dome rising 330 feet from the floor. The grand altar, 90 feet high and 50 feet wide, is composed of jasper and gilded bronze. Eighteen pillars, each 18 feet high, of red and green jasper, support an estrade on which the altar is placed. Porphyry and marbles of the richest description incrust the walls, and on either side are statue portraits of the kings. Directly under the high altar, so that the host may be raised above the dead, is a mausoleum built by Philip IV., from a design after the Roman pantheon. This burial-place is 36 feet in diameter, with walls of jasper and black marble. Here the remains of all the sovereigns of Spain since Charles V. repose in niches one above another. Another burial-place in one of the chapels is called the pantheon of the infantas. Several fine paintings adorn the church, but it is much shorn of its embellishments since it was plundered by the French. Benvenuto Cellini's marble "Christ," presented to Philip by the duke of Tuscany, and brought from Barcelona on men's shoulders, is still shown here, and an immense collection of saintly relics amassed by the founder may also be seen. The interior of the church is a triumph of architectural effect, grand, massive, and solemn. On its steps are 6 colossal statues in granite, with marble heads and hands, and gilt crowns. These are called the kings of Judaea. The edifice forms one side of a court, facing a finely sculptured portal, which opens twice for every Spanish monarch, once when he is carried through it after his birth, and once after his death, when 8 nobles and 8 priests bear him to the tomb. The royal apartments contain little worthy of notice, excepting two picture galleries, from which, however, most of the *chefs d'œuvre* have been removed to Madrid. The archel room of the great library is 194 feet in length, 32 in width, and 36 in height. The ceilings were painted in fresco by Bartholomew Carducci. The library was said before the French invasion to have contained 30,000 printed and 4,300 MS. volumes, but we have no accurate estimate of its present contents. It is believed to contain between 4,000 and 5,000 MSS., of which 567 are Greek, 67 Hebrew, and 1,800 Arabic. The Arabic MSS. are not accessible to visitors. A portion of the library was destroyed by fire in 1671, and again in 1761. The general aspect of the Escorial is that of a freshly erected pile, rising from the midst of plantations, and more imposing from its magnitude than from grandeur of architecture. The E. and W. terraces overlook the slopes; the N.

and W. sides front the mountain, and are connected with the village by a subterranean gallery tunnelled in 1770 as a means of communication during storms.

ESDRAS, Books of, two apocryphal books of the Old Testament, given as the 3d and 4th books of Ezra (the 2d being properly the book of Nehemiah), in several manuscripts of the Latin Vulgate, as well as in all printed editions anterior to the decree of the council of Trent, which declared the two additional books uncanonical. In the English authorized version of the Apocrypha they are called 1st and 2d Esdras; in the Clementine and Sixtine versions of the Vulgate they appear at the end of the volume, being inserted, as expressly stated, in order to "preserve from being altogether lost books which had been sometimes cited by some of the holy fathers." In all the manuscripts of the Septuagint, the first of these books, or the so called 3d of Ezra, precedes the canonical books of the Jewish scribe, which, in this version, include that of Nehemiah. It is a recapitulation of the history related in the canonical book of the same name, interspersed with some interpolations taken from 2 Chronicles, Nehemiah, and other sources. It is written in an elegant style, resembling that of Symmachus, though it appears to be rather a version than an original work. The name and age of the author or translator are unknown. The 2d Esdras or 4th of Ezra is of a different character from its apocryphal predecessor, and seems to owe its place among the uncanonical writings of the Old Testament only to the historical name which it bears. It contains a number of visions resembling those of the Apocalypse, related in a style acknowledged by prominent critics to rise occasionally to great sublimity of thought, energy of conception, and elegance of expression. This book also is supposed by some to be a translation, from the Hebrew or Chaldee. But both the original and the Greek translation mentioned by Clement of Alexandria having been lost, the book was believed to exist only in the old Latin version, until more recent discoveries enriched biblical literature with Arabic and Ethiopic translations. This book is ascribed to Ezra the scribe by Clement of Alexandria, and was regarded as prophetic by most of the fathers of the church, though it does not appear to have been known by Josephus. Jahn supposes the author to have been a Jew educated in Chaldea, and converted to Christianity, who flourished about the beginning of the 2d century of our era. Dr. Laurence maintains that the author was a Jew who lived shortly before the Christian era. He accordingly rejects, as interpolations, the first two chapters of the book, which furnish the chief argument for his acquaintance with the doctrines of Christianity. Dr. Lee believes the author to have been contemporary with the author of the book of Enoch, or rather to have written the latter work himself.

ESHER, a village and parish of Surrey, England, on the S. W. railway, 15 m. S. W. of London; pop. of parish (1851), 1,441. It is the

seat of Claremont House, built by Lord Clive, afterward occupied by the princess Charlotte and Prince Leopold, and still later the residence of the ex-king Louis Philippe and his family. Esher place, one of Cardinal Wolsey's mansions, is also in this parish.

ESK, the name of several rivers of Scotland. I. A river of Dumfriesshire, formed by the junction of the Black and White Esk, runs a short distance along the English boundary, enters Cumberland, and falls into the Solway frith, after a course of 24 m. II. A river of Edinburghshire, formed 1½ m. N. of Dalkeith by the junction of the N. and S. Esk, flows N., and empties into the firth of Forth at Musselburgh. III. **NORTH ESK**, a river of Forfarshire, rises among the Grampian hills, flows S. E., chiefly along the boundary between Forfarshire and Kincardineshire, and enters the German ocean near Montrose; length, 22 m. It has valuable salmon fisheries. IV. **SOUTH ESK**, a river of Forfarshire, rises in the Grampians, flows S. and S. E., and enters the German ocean near the mouth of the N. Esk. It forms a large basin at Montrose, but is navigable only a short distance from the sea. It has salmon fisheries.

ESMERALDAS, a province of Ecuador, in the department of Quito, lying about the mouth of the Esmeraldas river; area, 1,600 sq. m.; pop. estimated at 5,513. It is on the coast, and has several harbors, of which the most important is that of Esmeraldas, the capital of the province. Its soil is fertile, and produces abundantly cacao, tobacco, indigo, and many kinds of fruits. Its mountains are covered with valuable forests, and have unexplored mines; its rivers are rich in gold, and emeralds were formerly found in such abundance as to have given the name to the province.

ESNEH (the ancient *Latopolis* or *Lato*), a town of upper Egypt, on the left bank of the Nile, lat. 25° 30' N., opposite Taud, and 28 m. S. S. W. of Thebes; pop. about 4,000. It is a dirty, poverty-stricken place, with mud houses, and was selected in 1834 as a place of banishment for the Ghawazee or dancing women of Cairo and other females who offend against the rules of the police. It is the emporium of the Abyssinian trade, contains manufactories of cotton goods, shawls, and pottery, and is a celebrated camel market. It was anciently a city of great size and importance, the remains of which are mostly buried under large mounds covering the adjacent country. In the centre of the modern town, however, surrounded by filthy hovels, stands the portico of a great temple, in a fine state of preservation. It is supported by 24 massive and elegant pillars, each 5½ feet in diameter and 40 feet high. The portico is 112 feet long, 53 feet broad, and covered with sculptures and hieroglyphics. On its ceiling is a zodiac, like that of Denderah; over the dedication at the entrance are the names of Tiberius Claudius Cæsar, Germanicus, and Vespasian, and within occur those of Trajan, Hadrian, and Antoninus. It is known

to be a work of Roman times, and was finished in the reign of Vespasian. In 1843 Mehemet Ali had it cleared of the rubbish which filled the interior, and it is now used as a cotton warehouse.

ESPALIER (Fr., from Lat. *palus*, a pole), a kind of trellis-work used in horticulture, on which to arrange the branches of fruit trees, so as to train them into a horizontal direction, and to expose them to the light and heat of the sun. It is employed in the United States where it is desired to produce a great variety of fruits in small enclosures. The espalier is fastened to the walls or high fences of the garden, and dwarf pears and peaches are trained in this way. In England, apples, cherries, plums, and even gooseberries are thus trained, the espalier not being always fastened to the walls. In France and other parts of Europe the fastened espalier is principally used, and the peach and nectarine are raised on such frames. The espalier thus permanently secured possesses some advantages over the system of nailing the tree to the wall, which renders it more difficult to remove the insects that are apt to breed between the branches and the wall, and to wash and clean the trees. In American forcing houses, the peach is commonly trained on espaliers, so formed that the greatest amount of surface can be fairly exposed to the sun and air.—To train to espaliers, the fruit tree is selected when young, after the buds have made their first year's growth. The stem or trunk should be clean and straight. It is to be carefully planted in a properly prepared border, and headed down just before it begins to push out for growing. When the buds have pushed and grown 3 or 4 inches, it should receive a summer pruning. One shoot is trained perpendicularly, and the others are laid horizontally along the trellis bars, one or two each side of the stem, and about 9 inches apart. If the extremity of the leading shoot be pinched off, leaving about 15 inches, the summer-formed buds will push out in turn, and the lower ones upon it are to be trained out horizontally as they grow, at nearly equal distance apart. The extremities of these branches are to be shortened in again some time previous to the next spring's growth, and in midsummer the buds upon the leading shoots are to be all rubbed off, excepting the 8 uppermost; 2 of these are to be trained out horizontally, and the upper is to be the leader. By this repeated pruning and pinching, short stems are produced, and in due time the fruit-bearing buds will appear, which in the pear are of peculiar form, growing upon what are technically called fruit spurs, and in the peach and plum are distinguished by their fullness and roundness and other dissimilarities to leaf buds. Fan-training on espaliers is practised with the peach and nectarine especially, and sometimes with the apricot; this consists in training the branches so as to spread obliquely upward like the rays or sticks of a fan. With the pear and apple the horizontal mode is adopted. Many flowering shrubs can be trained

upon espaliers and trellises by careful attention, and any requisite form combining beauty and utility can be secured for ornamental purposes. The object in fruit culture, however, is to secure an abundance of fruit buds in confined limits, while affording sufficiency of light and sunshine. For this purpose no other plan seems so feasible as the espalier; but since the dwarfing of the pear on the quince stock has been practised, standard trees of dwarf dimensions, which can be planted near each other, and can be trained like shrubs or bushes, are preferred.

ESPARTERO, JOAQUIN BALDOMERO, duke of Vittoria, a Spanish soldier and statesman, born Feb. 27, 1792, in Granatula, province of Ciudad Real. He is the son of a wheelwright, received some instruction in his native village and in the neighboring town of Almagro, enlisted in 1808 as a common soldier, subsequently attended the military school at Cadiz, was made sub-lieutenant in 1814, engaged in 1815 in the war in Venezuela, attained in South America to the rank of general, and in 1824 was sent to Madrid as a bearer of despatches for the government. He returned to South America the next year only to witness the triumph of Bolivar and to be thrown into prison, from which he escaped after a few months' detention. After his arrival in Spain he displayed a large fortune, derived, it was said, from gambling in South America. In 1827 he married the beautiful daughter of a wealthy gentleman of Logroña. He was one of the first to declare himself in favor of the measure brought forward to secure the succession to the throne to Isabel II, and the regency during her minority to her mother, Queen Christina; and on the breaking out of civil war after King Ferdinand's death (Sept. 29, 1833), he took a conspicuous part against the Carlists, became commander-in-chief of the province of Biscay (Jan. 1, 1834), and soon after field-marshal and lieutenant-general of the royal forces (June 20, 1835). Although not always successful against the Carlists, he displayed more spirit and ability than any of his colleagues; and having protected Madrid against the insurgents (Aug. 1836), he was appointed general-in-chief of the army of the north, viceroy of Navarre, and in the following month captain-general of the Basque provinces. Soon afterward he drove the Carlists from the position of Luchana, and, assisted by the British fleet, raised the siege of Bilbao (Dec. 24, 1836), on which occasion he was created count of Luchana. In the mean time revolution was rife in Madrid, resulting in the proclamation of a new constitution, June 18, 1837, to which Espartero, as a member of the constituent cortes, gave his adherence. He forced the army of Don Carlos, which had advanced to the walls of Madrid (Sept. 12, 1837), to retreat, and drove it back across the Ebro. On April 27, 1838, he defeated near Burgos the army of the Carlist general Negri, and soon afterward near Penacerrada that of Gen. Guergue: and after gaining new and important

victories in May, 1839, he was created (June 1) a grandee of the first class with the title of duke of Vittoria and of Morella. Skilfully availing himself of the dissensions and calamities of the Carlists, and of his personal acquaintance with their general, Maroto (the successor of Guergue), who had been his companion in arms in South America, he succeeded in concluding a convention with him at Bergara (Aug. 29, 1839), by which 24 battalions of veteran Carlist troops acknowledged the supremacy of the queen. Don Carlos fled to France, the few troops that remained devoted to him were dispersed, and Cabrera himself, the most formidable Carlist leader after the death of Zumalacarreguy (1835), was at length overpowered by Espartero, and compelled to follow his master to France (July 6, 1840); and thus the war with the Carlists was at an end. But the strife of political parties, in which Espartero now took a more prominent part, continued to distract the country. A law interfering with the freedom of speech in the *ayuntamientos* or town councils, passed by the government and opposed by Espartero, became the signal for an insurrection. Espartero made a triumphant entry into Madrid and Valencia, whither he had been summoned by Christina, who proposed to place him at the head of a new administration. But in the course of a stormy interview with him, the queen suddenly determined to resign her office of regent (Oct. 10, 1840), and retired to France. Espartero became the chief of the government, and was confirmed in his position by a decision of the cortes (May 8, 1841), by which he was appointed regent of Spain during the remainder of the minority of Isabel. He resisted the encroachments of the holy see as well as those of the extreme republican party, quelled an insurrection in favor of Christina under O'Donnell, at Pamplona, defeated the attempts of Concha and Diego Leon to seize the young queen and to bribe the army, repressed the unruly spirit of the people in the Basque provinces, and, on Nov. 18, 1841, subdued Barcelona, the focus of the revolutionary politicians and the discontented industrial population. But within a year the country was again in open rebellion. A new and bloody conflict broke out at Barcelona. Espartero took the town (Dec. 1842) after a heavy bombardment. Violent outbreaks took place in many of the provinces. His refusal to grant an amnesty to political offenders who were partisans of Christina, and to dismiss some of his officers who had taken a conspicuous part in reducing the Barcelona insurgents, sealed the fate of his administration. His cabinet resigned. Revolution, promoted by the agents of Christina and supported by Concha, O'Donnell, and Narvaez, spread over the land. The junta of Barcelona declared the majority of Isabel (June 13, 1843), and deposed Espartero. Narvaez, putting himself at the head of the insurgents at Valencia, entered Madrid, July 22; and Espartero, deserted by all parties, was

received on board an English ship of war in the bay of Cadiz, July 30, whence he soon afterward set sail for England, arriving at Falmouth Aug. 19. He resided in London until Dec. 29, 1847, when he was recalled to Spain and created a senator. He took his seat in the senate, Jan. 13, 1848, but soon retired to Logroño, and took no part in the government until July 17, 1854, when an insurrection broke out, which again drove Christina and Narvaez from the country and replaced Espartero at the head of the government. His administration was marked by violent debates in the cortes on the political institutions of Spain, by the agitation of the question of the estates of the clergy, by a severe financial crisis, and by various other difficulties at home, while the Crimean war created some embarrassment in foreign relations. With a view of consolidating his government, he had appointed O'Donnell, the principal leader of Christina's party, minister of war, but this coalition could not last, and Espartero resigned in July, 1856. His resignation was followed by outbreaks in Madrid and other towns, in which Espartero, however, who has since lived in retirement, did not take any part.

ESPINASSE, ESPRIT CHARLES MARIE, a French general, born at Saissac, Aude, April 2, 1815, killed at Magenta, June 4, 1859. He served in early life in Algeria, assisted in the *coup d'état* of Dec. 2, 1851, and became an aide-de-camp of Napoleon III. In the Russo-Turkish war he was at first unsuccessful in an expedition in the Dobrodja (1854), where he and his troops were prostrated by the cholera; but he distinguished himself in 1855 during the battle of the Tchernaya and the storming of the Malakoff, and was appointed general of division. His devotion to Napoleon and his uncompromising energy of character caused him to be made minister of the interior and of public safety, Feb. 8, 1858, Orsini's attempt upon the emperor's life being made a pretext for investing a soldier with the functions of a civilian. But dictatorial and unpolished, he could not maintain himself in his office. M. Delangle became his successor (June 14, 1858), while the general received a seat in the senate. He was among the first to join the army in Italy, and fell early in the battle of Magenta.

ESPINASSE, M^{lle}. DE L'. See LESPINASSE.

ESPINEL, VICENTE, a Spanish poet, born in Ronda, Andalusia, about 1540, died in Madrid about 1630. His father's name was Francisco Goma, but, according to a prevailing custom among the ancient Granadan nobility, he adopted the name of his maternal grandmother. The incidents of his life, like the dates of his birth and death, are surrounded with obscurity, but it is certain that he was educated at Salamanca, and that he led an adventurous life in various parts of Europe. In the latter part of his life he held an ecclesiastical office in his native town, though he passed much of his time in the capital. He was through the whole of his career more or less in pecuniary trouble,

and died in great poverty, although he was the recipient of a pension from the archbishop of Toledo. His restless and sarcastic disposition contributed not a little to aggravate his difficulties, and alienated from him Cervantes and others of his friends. He was prominent among the Spanish poets of the 16th and 17th centuries, and the first poetical productions of Lope de Vega were submitted to his criticism. Some of his *canciones*, *redondillas*, pastorals, and elegies are spirited, picturesque, and harmonious in versification. He was also proficient in music, composed the music for the funeral service on occasion of the death of Philip II., and is said to have added a 5th string to the guitar, which soon led to the invention of the 6th. But his chief work is his sprightly, amusing, and characteristic "Life of Marcos de Obregon" (*Relaciones de la vida del escudero Marcos de Obregon*), which first appeared at Barcelona in 1618, and has since passed through several editions in Spain, of which that of Madrid, 1804, is the last. An English translation was made by Algernon Langton (London, 1816). Tieck wrote an imitation in German. Voltaire accused Le Sage, who was no favorite with the sage of Ferney, of plagiarism in connection with this work, and denounced the "Gil Blas" as taken entirely from Espinel's "Marcos de Obregon."

ESPIRITO SANTO, a maritime province of Brazil, bounded N. by the province of Bahia, S. by Rio Janeiro, W. by Minas Geraes, and E. by the Atlantic; area, 23,000 sq. m.; pop. according to government returns published in 1856, 51,300, about $\frac{1}{4}$ being slaves; capital, Vittoria. It has a healthy climate and a rich but ill cultivated soil, watered by numerous rivers which rise among the Cordilleras and flow into the Atlantic. Canoes ascend these streams nearly to their sources, and coasting vessels, carrying on an export trade in rum, unrefined sugar, mandioca, flour, rice, maize, cotton, timber, dyestuffs, drugs, and salt fish, frequent the deep and safe harbors formed at their mouths. Along the coast are the islands called the Abrolhos. Opposite to them, on the river Caravellas, is the town of Caravellas, the most commercial town of the province, and containing a German colony. The interior, covered with mountains and dense forests, is peopled almost wholly by Indians. Among these are the Botocudos, noted for their bravery and cannibalism.

ESPRONCEDA, JOSÉ DE, a Spanish poet, born at Almendralejo, Estremadura, in 1808, died May 23, 1842. The liberal political sentiments of his early effusions caused him to be sent for some time into exile. While in France, he took part in the revolution of 1830. Under the administration of Espartero he received a diplomatic appointment at the Hague (1840). He devoted much attention to Byron's works, which he endeavored to imitate. His best poem, though unfinished, is his *El Diablo Mundo*, and his best novel is his *Don Sancho Saldaña*. An

edition of his works without the *Diablo Mundo* was published in Madrid in 1840, and one including it in Paris in 1856.

ESQUIMAUX, a name given to a race who are the sole inhabitants of the shores of all the seas, bays, inlets, and islands of America N. of lat. 60° N., from the E. coast of Greenland to Behring's straits. Their habitations stretch along the Atlantic on the coast of Labrador to the straits of Belle Isle, and they are found on the Pacific as far as the peninsula of Alaska, and even to some extent on the opposite coast of Asia. The entire length of coast under their control is computed at not less than 5,400 miles exclusive of inlets, and the language spoken throughout this great range is intrinsically the same. The name of Esquimaux is derived, according to Charlevoix, from the Algonquin word *Eskimantick*, which signifies "eaters of raw fish." Sir John Richardson, however, thinks it is of Canadian origin, and derived from the phrase *Ceux qui miaux* (*miaulent*), "Those who mew," referring to their peculiar shout as they surround trading vessels in their boats. He adds that the word is unknown to the Esquimaux, who invariably call themselves *In-it*, "the people." Crantz describes the Greenlanders, between whom and the other tribes of Esquimaux there are few points of difference, as a small but well proportioned, broad-shouldered people, generally less than 5 feet in height, with high cheek bones, flat faces, small lustreless black eyes, round cheeks, small but not flat noses, small round mouths, long, straight coal-black hair, large heads and limbs, and small soft hands and feet. They root out the beard, and are inclined to corpulency. Their body is of a dark gray color, but the face brown or blue. This brown color seems not altogether natural, because their children are born as white as others, but is due in part to their habits; for they are constantly handling grease, and seldom wash themselves. Lesson describes them as superstitious to excess, and possessed of those vague religious sentiments which pervade all the northern tribes. Polygamy is practiced, and women are regarded as creatures of an inferior order, to be disposed of by the men according to their pleasure. Their dwellings are almost invariably built near the sea-shore, and are either permanent or temporary according to the situation and the materials at the disposal of the workman. In Greenland, where their permanent dwelling is built of stone cemented by turf as a substitute for mortar, it is usually not more than 6 or 8 feet high, and is covered by a flat roof of wood and turf. It has neither door nor chimney, and the floor is divided into compartments by skins attached to the posts that support the roof. Each family has a separate apartment, and each apartment a window of seal skin dried, which is white and transparent. Benches are used as seats during the day and as couches during the night, the bedding being composed of deer skins. In Gilbert sound the houses are made of wood, and

at Regent's bay, according to Sir John Ross, the roof is arched, and the habitation sunk 3 feet in the ground, a description of house generally found among the Esquimaux of Labrador; but the most remarkable houses are those built of the bones of whales and walrus described by Sir Martin Frobisher and Sir Edward Parry. They also frequently construct dwellings of snow and ice. Both Dr. Kane and Dr. Rae, borrowing the suggestion from the natives of this high polar region, constructed dwellings of snow, which they found to be both useful and agreeable. The dress of the Esquimaux consists of furs, in the preparation of which they exercise a degree of ingenuity superior to that of the most skilful furrier. The winter coat is usually made of seal skin, while the summer coat consists of that of the reindeer; but every variety of fur is occasionally used. At Prince William's sound the natives wear skins of the sea otter, fox, raccoon, martin, seal, and water fowl. At Schismareff inlet those of the reindeer and dog are generally used, at Regent inlet those of the polar bear, and at Melville peninsula those of reindeer. The overcoat is supplied with a large hood, often bordered with white fur of the deer, which when drawn over the head presents a lively contrast with the dark face of the wearer. Those worn by the females have a much larger hood than those used by the males, which not only furnishes a covering for the head but a cradle for the infant. The boots of the females are remarkable, and are sometimes made so large in the leg as to resemble a leather sack, which gives a singular and ludicrous aspect to the whole figure. These capacious pouches are used as pockets, as temporary beds for infants, and, when in the vicinage of white men, as receptacles for stolen goods. As they are much upon the water, they devote considerable attention to the construction of their boats. These are of two kinds, the *caiak* or men's boat, and the *oomiak* or women's boat. The *caiak*, first described by Baffin, is adapted but for one person; it is about 16 feet long, 2 feet broad in the centre, and 1 foot deep, and bears a resemblance to the weaver's shuttle. The bottom is rounded and has no keel. The frame is kept stretched above by 22 little beams, and 2 strong battens run from stem to stern, which toward the centre are attached to a hoop of bone of sufficient size to admit the body. The frame is entirely covered, with the exception of a circular hole in the centre, with fresh-dressed seal or walrus skin. When complete the boat weighs about 60 pounds, and is so constructed that it can be carried on the head without the aid of the hands. The *oomiak* is from 20 to 25 feet long, 8 feet broad, and capable of accommodating from 10 to 20 persons. It is composed of the same materials as the *caiak*, and is often furnished with a lug-shaped sail, formed of the intestine of the walrus, sewed together with great skill in breadths of about 4 inches, and weighing less than 4 pounds. The mast has a neat ivory sheave for the halyards

to run on, and is placed well forward. Much taste is displayed upon the bow and stern of the *oomiak*, but the Esquimaux chiefly prides himself upon the beauty and speed of his *caiak*, in which he defies the storm, and does not hesitate to approach and give battle to the polar bear and other monsters of these high northern seas. Next to his boat the Esquimaux attaches most importance to his sledge, which is drawn by dogs. It is sometimes constructed of wood, but bone sleds are almost exclusively used at Schismareff inlet and Regent's bay. At Regent's inlet the sled is made of a number of salmon packed together in the form of a cylinder about 7 feet long, encased in skins taken from canoes, and well corded with thongs; 2 of these cylinders are pressed into the shape of runners, and having been left to freeze, are secured by cross bars made of the legs of the deer or musk ox. The bottom of the runner is then covered with a mixture of moss, earth, and water, upon which is deposited about half an inch of water, which congeals in the act of application. These sleds travel more lightly than those shod with iron; but as they cease to be of service when the temperature rises above the freezing point, they are then taken to pieces, and the fish being eaten, the skins are converted into bags and the bones are given to the dogs. The Esquimaux hunt with bows and arrows, spears, and slings. They are fond of ornaments, and carve with much skill. Capt. Logan informs us that he found on the E. coast of America models of men, women, and children, of beasts, birds, and fishes, executed in a masterly style, and with no mean knowledge of anatomy. The ivory or walrus tusks of which they form their models are cut by continued chopping with a knife, one end of the ivory resting on a soft stone, which serves as a block. To smooth and polish the work when finished, a gritty stone is used as a file, and kept constantly wet with saliva. The impressions of Dr. Kane and Dr. Rae, the two most recent travellers among the Esquimaux, are somewhat at variance; while Dr. Kane had reason to doubt their good faith and to suspect them of treachery, Dr. Rae found them simple, well meaning, and trusty. Richardson represents them as scrupulously honest toward each other, but utterly regardless of the property rights of strangers. They subsist almost exclusively upon fish and animal food, which the rigor of the climate enables them to eat raw, and in large quantities. Fat of animals and fish oil constitute their chief delicacies. Mr. John Simpson, who was physician of the ship *Plover*, Com. Maguire, which wintered twice at Point Barrow (1852 and 1854), wrote "Observations on the Western Esquimaux and the country they inhabit," which are contained in the "Further Papers relative to the recent Arctic Expedition in search of Sir John Franklin," presented to the English parliament in 1855. He states that their principal settlements at Point Barrow, Cape Smyth, Point Hope, and Cape Prince of Wales, are inhabited during the whole year;

but Wainwright inlet, Icy cape, Port Clarence, and Norton sound, the coasts of Kotzebue sound, and other settlements and huts along the coast, are only inhabited during the winter and deserted in summer. Their commercial places are King-ing on Cape Prince of Wales, Sesua-ling at the mouth of the Nu-na-tak, Nig-a-lek at that of the river Cobrille, and Nu-wu-ak on Point Barter. Four or five Asiatic boats are engaged in the trade, and land their freight at Sesua-ling, where a species of fair is held toward the end of July, which is distinguished not only for its active commercial but also for its pleasant social character. Dealers who reside on the shores of the Nu-na-tak take the most active part in the business, and distribute the merchandise among the people of the interior. They either forward them or bring them annually in ships to the river Colville, where they meet their friends from Point Barrow. In the beginning of August the goods are taken from thence to Point Barter, where they are bartered for English and other products. According to Mr. Simpson, Sir John Franklin was mistaken in his belief that a Russian settlement existed on the Colville river, and that the Russian settlers were called Nu-na-tang-menn, this being the name applied by the Esquimaux to the dealers from the Nu-na-tak, who are the factors of the Russian implements and wares which are found along the N. coast.—It is a question with what portion of the human family the Esquimaux are to be classified. Most ethnologists have classed them with the Mongolians; both Mr. Gallatin and Mr. Duponceau, however, give to them the same origin as that of the hunting tribes of North American Indians, an opinion in which Dr. Prichard entirely coincides. Mr. Gallatin says that "there does not seem to be any solid foundation for the opinion of those who would ascribe to the Esquimaux an origin different from that of the North American Indians. The color and features are essentially the same, and the differences which exist, particularly in stature, may be easily accounted for by the rigor of climate, and partly perhaps by the nature of their food."—See "Synopsis of the Indian Tribes of North America," by Albert Gallatin, in *Archæologia Americana*, vol. ii. (Worcester, 1836), and the narratives of Franklin and the other arctic explorers.

ESQUIRE, or SQUIRE (Lat. *scutifer*; old Fr. *escuier*, a shield-bearer), originally a warrior armed with shield and javelin. Under the later Roman emperors the name was applied to soldiers of the most approved valor, to whom especially was assigned the defence of the palace and person of the emperor. The name was adopted in France, from the earliest period of the monarchy, to designate those holding the first rank in the army, whose bravery was rewarded with free grants of land, and who were styled gentlemen or nobles. By degrees the quality of nobility was distinguished from that of esquire, and a person ennobled for civil services could not take the latter title,

which could be gained only in the profession of arms. In the ages of chivalry the office of esquire followed that of valet, or page, and was the last degree of apprenticeship before attaining the honor of knighthood. (See CHIVALRY.) Esquires were attached to the courts of great lords and to the persons of knights, and were divided into various classes according to the offices which they performed. The esquire of the person accompanied his master almost everywhere, carried his helmet, armor, shield, gauntlets, and banner, held the stirrup when he mounted, armed him at the moment of combat, gave the martial cry as he entered battle, and supported him if he was overthrown in the fight. The esquire of honor did the honors of the castle, made preparations for festive assemblies, conducted guests to their chambers, and dressed and undressed his master. In war he kept guard over the prisoners taken by his master. The esquire of the chamber, or chamberlain, had charge of the gold and silver, especially of the plate for the table service. These 8 esquires were treated with confidence and familiarity, and were permitted to approach their master or mistress at any time. The esquire trenchant always stood at the repasts, and his office was to carve the meats and distribute them to the guests. The esquire of the stable was an important officer, his duty being not only to take charge of the horses, but also to keep the arms of the knight in good condition, and to guard against any defect which might be dangerous or fatal to his master in battle. Esquires of all classes were devoted to learning the arts and skill of their master, expecting, usually not before 7 years of service, their elevation to the dignity of knighthood, with the right to assume golden spurs. After the decline of chivalry the title of esquire remained in France attached to various offices. The office of grand esquire or equerry was one of the most considerable in the kingdom, with extensive prerogatives, and the disposal of numerous smaller offices, such as the esquires of the stables. Upon the entrance of the king into cities, he marched immediately before him, carrying the royal sword. Upon the death of the king the horses and harnesses of the royal stable became his property. This office and those dependent upon it were suppressed at the revolution, were revived under the empire and the restoration, again disappeared in 1830, and some of them have been reestablished by Napoleon III. In England the title of esquire belongs by right of birth to the sons of younger sons of dukes and marquises; to all the sons of earls, viscounts, and barons; to the eldest sons of baronets and of knights of all the orders. The title is also given to the officers of the king's court and household; to the officers of the army and navy down to the captain inclusive; to doctors of law, barristers, physicians, justices of the peace while in commission, and the sheriffs of counties for life. The heads of many old families are also

deemed esquires by prescription. The title is now hardly more than complimentary in England, as in the United States, and is very generally affixed to the names of gentlemen in the superscription of letters.

ESQUIROL, JEAN ÉTIENNE DOMINIQUE, a French physician and philanthropist, born in Toulouse, Jan. 4, 1772, died Dec. 12, 1840. He was pursuing his studies at Paris when the revolution broke out, and led him to enter the medical service of the army. In 1794 he attended the military hospital in Narbonne, and on his return to Paris he became Dr. Pinel's assistant in the *Salpêtrière*, and took at the same time an able part in the editing of Pinel's medical journal (*Médecine clinique*). In 1799 he founded a lunatic asylum, which became the model of all similar institutions afterward founded in France, and subsequently spent much time in visiting the various lunatic asylums of France. He was appointed physician to the *Salpêtrière* in 1811. In 1817 he opened a course of clinical lectures, in which he pointed out the reforms needed in the treatment of lunatics, and at the same time he prevailed upon the government to appoint a commission on the subject, of which he became the most prominent and zealous member. The new lunatic asylums at Rouen, Nantes, and in the other French cities, as well as many other improvements calculated to benefit the insane, owe their origin to his benevolence. In 1823 he became inspector-general of the university for the faculties of medicine, and in 1825 physician-in-chief to the royal institution for the insane at Charenton. In 1830 he was deprived of his offices in consequence of his opposition to the July revolution, but he continued to the time of his death in the practice of his profession. He contributed many important papers to the *Encyclopédie des gens du monde*, and to the great *Dictionnaire des sciences médicales*. In 1838 he published a more elaborate work: *Des maladies mentales, considérées sous les rapports médical, hygiénique, et médico-légal* (Paris, 2 vols. 8vo.)

ESS, HEINRICH LEANDER VAN, a German Roman Catholic theologian, born in Warburg, Westphalia, in 1772, died in Affolterbach in 1847. He entered the Benedictine order in 1793, and officiated as pastor in a village from 1799 to 1813, when he became pastor and professor of theology at the university of Marburg. Conjointly with his cousin and fellow Benedictine, Karl van Ess (1770–1824), he published a new German translation of the New Testament (Brunswick, 1807; 20th ed., Sulzbach, 1830), which is highly valued. They also published *Das Alte Testament* (Nuremberg, 1819), and *Die Heilige Schrift Alten und Neuen Testaments* (Sulzbach, 1840). He made himself widely known by his endeavors to promote the reading of the Bible among the Catholics of Germany, for which purpose he wrote *Auszüge aus den heiligen Vätern und andern Lehrern der kath. Kirche über das nothwendige Bibellezen* ("Extracts from the Holy

Fathers and other Teachers of the Catholic Church on the Necessity of Bible Reading," 2d ed., Sulzbach, 1822), and *Pragmatica Doctorum Catholicorum Tridentini circa Vulgatam Decreti Sensum nec non licitum Originalis Usus Testantium Historia*, a prize essay (Sulzbach, 1816; German translation, Tübingen, 1824). His views on this subject did not meet with the approbation of the bishops of Germany or of the pope.

ESSÉ, a French village in the department of Ille-et-Vilaine, near Vitry; pop. 1,800. In its environs is one of the finest druidical monuments of France, called *Roche aux fées*, consisting of 43 large rough blocks of stone, 34 upright, supporting 8 others which form a roof.

ESSEN, HANS HENRIK, count, a Swedish general, of Livonian descent, born in Kafiläs, West Gothland, in 1755, died July 28, 1824. He was educated in the universities of Sweden, and his attainments as well as his graceful and chivalric bearing caused him to become a favorite of Gustavus III. He accompanied that prince in his travels abroad and in the campaign of Finland, was of great assistance to the king in the course of this campaign, and was with him on the fatal night when Gustavus, although warned by Essen against the designs of his enemy, persisted in attending the masked ball, where he was murdered by Anckarstroom. In 1795, after having accompanied the duke of Südermanland and the young prince Gustavus Adolphus to St. Petersburg, Essen was appointed governor of Stockholm. Subsequently he became governor-general of Pomerania and of Rügen; and in 1807, as commander-in-chief of the Pomeranian army, he distinguished himself by his defence of Stralsund, and brought about an honorable truce with France. But the king was dissatisfied with Essen, and himself assumed the command of the army, which caused him to retire from active service until the accession of Charles XIII. to the throne. Charles created him a count and member of the council, and appointed him ambassador at Paris. Here his efforts were successful, and Pomerania, before passing eventually into the possession of Prussia, was for a short time restored to Sweden. Under Bernadotte he marched in 1813 at the head of the Swedish army against Norway; and when the two countries were united, he became governor of Norway, with the title of Norwegian field marshal and chancellor of the university of Christiania. In 1816 he was removed from this position, but in 1817 he was made governor-general of the old Swedish province of Scania.

ESSENCES. See ESSENTIAL OILS, and EXTRACTS.

ESSENES, a remarkable Jewish sect, not mentioned in the Jewish or Christian Scriptures, and concerning whom the only original sources of information are passages in the works of Josephus and Philo, both of whom lived about the time when the Essenes had reached their highest point of development. Philo, a

disciple of the Alexandrian philosophy, and attracted by their mystical and speculative turn, gives the fuller instruction concerning their doctrines. Josephus, who lived in Palestine where the community flourished, and was according to his own statement in early life a member of it, treats of them particularly in their outward relations. The Essenes first appear in history in the latter half of the 2d century B. C., as a society of piously disposed men, who in the solitudes on the western side of the Dead sea sought a retreat from the corruptions and conflicts of the world. They lived an austere life, held their property in common, wore a white robe, prayed and meditated continually, made frequent ablutions, for the most part renounced marriage, and often practised medicine. On account of the latter practice some, as Bellermann and Gfrörer, identify them with the Therapeutæ, and find the origin of their name in the Aramaic word *ܐܬܪܐ*, to cure. They sacrificed no animals, and instead of going themselves to worship in the temple of Jerusalem, they sent their offerings. Contemning logic, metaphysics, and even physical science, as useless, they gave their attention only to ethics, recognized no other authority than their own sacred books, and taught the equality of men and the entire supremacy of destiny. Abstinence and labor were the chief features of their life. Their number at the beginning of the Christian era was about 4,000, and during the religious and political storms which swept over Palestine in the 1st and 2d centuries, they disappeared from view, perhaps by being confounded with the Christian ascetics. In the obscurity which covers their origin and the specialities of their conduct and ideas, they have been variously compared to the old Hebrew schools of prophets, the Greek Pythagoreans and stoics, the Christian monks, and the modern Quakers. De Quincey has sought to identify them with the early Christians, who, surrounded by dangers, assumed the name and mode of life of the Essenes as a disguise, alike impenetrable to Jewish or Roman enemies, and to timid or treacherous brethren. Monographs on the Essenes have been written by Bellermann (Berlin, 1821), Sauer (Breslau, 1829), and Leutbecher (Amsterdam, 1857).

ESSENTIAL OILS, called also volatile oils, and distilled oils, oily products derived from plants, generally by distilling portions of them with water. The aqueous vapor which passes over carries with it the vapor of these oils, though their boiling point is often higher than that of water. They condense together in the receiver of the still, the oil commonly floating upon the water, sometimes sinking beneath it. A portion appears to be taken up by the water, giving to it the peculiar odor and properties of the oil in a less degree. This is called medicated and perfumed water. The oils contain in a concentrated form the fragrance and essential properties of the plant, or of the portion of it employed, and when kept dissolved in alcohol constitute the essences. They may sometimes

be obtained by expressing the parts containing them, as the rind of the orange and lemon; and sometimes they are so evanescent as to escape in the ordinary mode of securing them by distillation with water. The method then adopted, as in securing the oil in which lies the delicate fragrance of the tuberose, narcissus, jasmine, &c., is to arrange the flowers in layers with cotton imbued with some fixed and inodorous vegetable oil. This gradually absorbs the volatile oil of the flowers, and when the cotton is afterward digested in alcohol, the volatile oil is taken up by this fluid, and an essence is obtained. It may in some cases be separated also by distilling the cotton with water or alcohol. The odor of the oil is often less agreeable than that of the plant, which is probably owing to its greater concentration, as by dilution it is made more pleasant. The oils are often colored some shade of red, brown, yellow, green, or blue, but this is not always fixed. Their taste is hot and pungent, but made pleasantly aromatic by diluting them. Some, however, are poisonous. They burn with a bright and often smoky flame. The feeling of them upon the hand is not greasy like that of the fixed oils, but rough, and a cork moistened with them grates harshly when turned in the phial. Their specific gravity varies from 0.84 to 1.17. They boil at various degrees, some at 320° F., and a few others require a higher temperature. Exposed to the air and light at ordinary temperatures, they absorb oxygen, become of a darker color, of thicker consistency, and are finally changed into resin, sometimes into acid compounds. Most of them consist, like the fixed oils, of a thin fluid and a solid product, which may be separated at a cold temperature by compressing the substance between folds of paper. The camphor-like product called by Berzelius stearoptene is retained within the folds, while the oily fluid called elaiopene passes through. The ultimate analysis of the essential oils affords in most instances carbon, hydrogen, and oxygen. Some, however, prove to be hydrocarbon, containing no oxygen; and in these the proportion of carbon is between 88 and 90 per cent., and of hydrogen between 11 and 12 per cent., which would be expressed by the formula $C_n H_m$. Nitrogen is found as a constituent of some of them, and sulphur is met with in the oils of mustard and of horse radish. The agreeable odors retained by many of the oils cause them to be largely used in perfumery. Their medicinal properties also render many of them valuable agents in pharmacy, especially as powerful stimulants. Some are largely employed in the manufacture of paints and varnishes, and some have been used for illuminating purposes.—Essential oils are frequently adulterated. The presence of fixed oils added to them for this purpose may be detected by the greasy stain left upon paper moistened with the liquid and exposed to heat sufficient to drive off the volatile oil. Alcohol is detected by various tests, as by adding water

and agitating the mixture, which becomes milky if alcohol is present, and the bulk of the oil is reduced as the fluids separate on standing, by the alcohol leaving it and going with the water. A piece of potassium as large as the head of a pin will remain nearly 15 minutes in contact with a dozen drops of pure oil without change; but if it disappears in 5 minutes, the oil contains at least 4 per cent. of alcohol; if it disappears in one minute, it contains at least 25 per cent. Fused chloride of calcium is also used to abstract alcohol from the oils. When the high-priced oils are adulterated with the cheaper kinds, a thorough practical acquaintance with the physical properties of the oils can alone serve to detect the imposition. The odor of oil of turpentine when used for this purpose is concealed, until the oil is dissolved in alcohol, and water is added, when both the odor and flavor are easily recognized. The oils require to be kept in small bottles entirely filled, well stopped, and excluded from the light.—By means of recently devised chemical processes artificial essences imitating the flavors of various choice fruits are prepared from substances which would seem entirely unfitted for producing such results. Thus butyric acid, a product of butter or putrid cheese, being converted into an ether, cannot be distinguished from that prepared from the pineapple, and may be used equally well with the latter to flavor rum to produce the celebrated pineapple rum. The fetid fusel oil, separated from brandy and whiskey in rectifying these liquors, produces, when distilled with sulphuric acid and acetate of potash, an essence of pears; and if for the acetate of potash bichromate of potash be substituted, the product is an essence of apples. By similar methods a variety of other flavors are obtained; and though when concentrated they are acrid, they become very agreeable when used as flavoring in proportions of a drop to an ounce or two ounces. At the great exhibition of 1851 the ices prepared for the refreshment of the visitors were flavored by these artificial essences. Some of the choicest perfumes are by similar chemical processes prepared from substances which seem strangely foreign to their nature.

ESSEQUIBO, a district of British Guiana, now united with the co. of Demerara, and comprising the regions drained by the great river from which it takes its name; pop. in 1851, 24,925, of whom about 15,000 were natives of the district. Nearly all the land west of the Essequibo river is fertile, but uncultivated, and peopled almost wholly by small tribes of Indians. Essequibo was settled by the Dutch in 1627, and surrendered to the English in 1781, but was restored in 1783. It was again taken in 1808, since which it has remained a British colony.—**ESSEQUIBO**, a large river traversing the above district, formed by the union of several small streams which rise in the Sierra Arica or Acaray, near the S. boundary of the territory, flows N. E. and N., and after a course

of about 450 m., much of which lies through magnificent forests, enters the Atlantic in the N. W. part of the colony, by an estuary 14 m. wide. It forms many islands, 3 or 4 of which, of considerable size, are in its estuary. The *manati*, or river cow, the electric eel, and the *peri* or *omah*, a voracious fish about 2 feet long, remarkable for the strength of its jaws and teeth, are inhabitants of its waters. Its entrance is dangerous even for small craft, on account of numerous banks of mud and sand, and its course is obstructed by several falls and rapids, the lowest of which are 50 m. from its mouth. They can be passed by small vessels, though not without danger. At a distance of 45 m. from the sea, where it enters the low plain, the river is a mile wide, and gradually increases in width to its mouth. One of its sources was reached by Sir R. Schomburgk, in lat. 0° 41' N. Its principal affluents are the Ripunony or Rupunoony (220 m. long), Masse-roony, and Cuyuni. The Dutch formerly had, on the banks of this river, indigo, cacao, and cotton plantations, all traces of which are now covered by the dense vegetation of the forests. Gold has been found along the upper course of the stream.

ESSEX, the name of counties in several of the United States. I. A N. E. co. of Vt., bounded N. by Canada, and E. by the Connecticut river, which separates it from New Hampshire; area, 790 sq. m.; pop. in 1850, 4,650. It is traversed by the Grand Trunk railway from Portland to Montreal. The surface is rough and mountainous, with numerous small lakes and ponds scattered over it. The soil is well watered, but, except in the valley of the Connecticut, not remarkable for fertility. Potatoes, oats, and grass are the staples. In 1850 the productions amounted to 94,124 bushels of potatoes, 45,597 of oats, 14,972 tons of hay, 292,615 lbs. of butter, and 122,321 of cheese. There were 8 churches in the county, and 1,666 pupils attending public schools. Organized in 1792, and named from Essex, England. Capital, Guildhall. II. A N. E. co. of Mass., bounded N. by New Hampshire, and E. and S. E. by the Atlantic and Massachusetts bay, and traversed by the Ipswich and Merrimack rivers, the latter of which is navigable as far as Haverhill by vessels of 200 tons; area, about 500 sq. m.; pop. in 1855, 151,018. The surface is generally rough and the soil hard and rocky. It is carefully cultivated, however, and in many places has been rendered very productive. The chief sources of wealth are commerce and the fisheries, for the prosecution of which the long line of sea-coast broken by beautiful bays offers great advantages. The interior towns are extensively engaged in the manufacture of leather, shoes, and cotton. The productions in 1855 were 186,026 bushels of Indian corn, 1,260 of wheat, 16,192 of rye, 30,355 of oats, 290,286 of potatoes, 36,394 tons of hay, and 533,853 lbs. of butter. There were 20 cotton mills, 23 woollen mills, 2 carpet factories, 1 worsted factory, 1

linen factory, 1 silk factory, 99 forges, 6 manufacturing of steam engines and boilers, 8 of other machinery, 4 of iron railing, &c., 4 of paper, 78 of cars, coaches, and wagons, 23 of soap and candles, 9 of gas, 3 distilleries, 4 breweries, 99 tanneries, and 15 boat yards. In 1859 it had 23 newspapers and magazines, and 204 churches. Railroads leading to Boston, Gloucester, Portsmouth, Portland, Manchester, and numerous other places, pass through the county. It was organized in 1642. Seats of justice, Salem, Ipswich, and Newburyport. III. A N. E. co. of N. Y., bordering on Lake Champlain, and partly bounded on the N. by the river Au Sable; area, 1,656 sq. m.; pop. in 1855, 28,539. The country along the lake shore is tolerably level, but the N. W. part is occupied by the Adirondac mountains, which are covered with thick forests. Tahawus or Mt. Marcy, 5,337 feet high, is the principal summit, and the highest in the state. The county is drained by the head waters of Hudson river, and by Bouquet and Scroon rivers, which afford valuable water power, and has numerous small but picturesque lakes. The soil is well watered and productive, yielding fair crops of Indian corn, hay, and potatoes. The productions in 1855 were 46,493 bushels of wheat, 105,369 of Indian corn, 234,946 of oats, 318,021 of potatoes, 39,140 tons of hay, 625,542 lbs. of butter, and 134,735 of wool. There were 8 woollen mills, 2 carding mills, 25 iron manufacturing, 2 furnaces, 1 paper mill, 16 grist mills, 73 saw mills, 3 newspaper offices, 176 schools, and 51 churches. Iron, limestone, plumbago, and marble are the principal minerals. The county was formed from a part of Clinton in 1799. Capital, Elizabethtown. IV. A N. E. co. of N. J., bounded E. by Passaic river, Newark bay, and Staten Island sound, and W. by Passaic river; area in 1855 (since which time Union co. has been formed from its S. part), 450 sq. m.; pop. 95,199. The general character of the surface is level, but there are two elevated ridges in the western part known as First and Second mountains. Much of the soil is highly fertile, producing grain, potatoes, and good pasturage. In 1850 it yielded 297,076 bushels of Indian corn, 151,765 of oats, 159,148 of potatoes, 29,287 tons of hay, and 378,233 lbs. of butter. There were 6 cutlery and 16 edge tool manufactories, 13 iron foundries, 3 brass foundries, 1 type foundry, 13 machine shops, 11 patent leather manufactories, 16 flour mills, 15 paper mills, 3 manufactories of India rubber, 3 of woollen, 2 of cotton, 2 of shawls, and a great number of minor establishments. There were 80 churches, 9 newspaper offices, 7,475 pupils attending public schools, and 3,714 attending academies and other schools. The New Jersey, New Jersey central, and Morris and Essex railroads, and the Morris canal intersect the county. Organized in 1710. Capital, Newark. V. An E. co. of Va., bounded N. E. by Rappahannock river; area, about 300 sq. m.; pop. in 1850, 10,206, of whom 6,762 were slaves. It has an uneven surface in the W. part; the

soil is generally sandy, of little natural fertility, but greatly improved by the use of marl, guano, and lime. The chief staples are wheat and Indian corn. The productions in 1850 amounted to 391,895 bushels of Indian corn, 104,840 of wheat, and 57,747 lbs. of butter. There were 11 churches, and 216 pupils attending public schools. The county was formed in 1692. Capital, Tappahannock. Value of real estate in 1856, \$2,069,435.

ESSEX, a S. W. co. of Canada West, comprising a peninsula between Lakes St. Clair and Huron, and having an area of 677 sq. m.; pop. in 1851, 16,817. It is traversed by the Great Western railway, the W. terminus of which is at Windsor in this county. Capital, Sandwich.

ESSEX, a county on the E. coast of England, bounded S. by the river Thames; greatest length from S. W. to N. E., 60 m; greatest breadth, 45 m; area, 1,657 sq. m.; pop. in 1851, 369,318. Except in the N. W., where there is a continual succession of hill and dale, the surface is nearly level, and in the S. and E. is partly occupied by large marshes. The soil is fertile, and the farms are accounted among the best in the kingdom. Grain, especially wheat, which is of excellent quality, is the staple production. The production of veal, for which Essex is famous, forms an important branch of agricultural industry. Valuable fisheries and oyster beds furnish employment to the inhabitants of the coast and adjacent islands. About 15,000 bushels of oysters are taken every season, and a capital of between £60,000 and £80,000 is invested in the trade. Silk is manufactured, and straw plait is made for London use. The principal channels of communication are the Eastern Counties railway and the rivers Thames, Lea, Stort, Chelmer, Stour, and Colne. Chelmsford, the county town, Colchester, Harwich, and Maldon are the chief towns. The county returns 4 members to parliament.

ESSEX, EARLS OF. See DEVEREUX.

ESSLING. See ASPERN.

ESSLINGEN, a town of Würtemberg, Germany, capital of a bailiwick of the same name, situated on the Neckar, on the railway to and from Stuttgart; pop. 7,920. It is a very active commercial and manufacturing town. The locomotives made there are celebrated, as also a species of wine called *Esslinger Champagner*. It contains a normal school, a school for the deaf and dumb, a ragged school, and an establishment for the cure of nervous affections. In the neighborhood, on the Rothenberg, is situated the Greek chapel, which contains the statues of the four evangelists by Dannecker and Thorwaldsen.

ESTAING, CHARLES HECTOR, count d', a French naval officer, born at the chateau of Ruvel, in Auvergne, in 1729, executed in Paris April 28, 1794. He first joined the army, served under Lally-Tollendal in India as brigadier, and was made prisoner at the siege of Madras in 1759, but released on parole. He then enter-

ed the navy, and inflicted great damage on the English in the East, but on his return was captured near Lorient by the British cruisers. The treatment to which he was subjected at Portsmouth, on pretence that he had broken the parole given at Madras, led him to vow eternal hatred to England; and in 1778, having reached the grade of lieutenant-general of the navy, and refused the rank of vice-admiral, he took command of a fleet of 16 vessels designed to co-operate with the United States. He arrived in Delaware bay in July, and in August made a demonstration against Newport, obliging the British to destroy 6 of their frigates lying there, but failed in the main object, owing to the inability of the Americans to come to his support in proper season. His fleet was soon after shattered in a storm, while endeavoring to come to action with the ships of Lord Howe; whereupon he proceeded to Boston to refit, after a sharp quarrel with Gen. Sullivan, who wished him to renew the attack upon Newport. The count's course was bitterly condemned by the American people, and some even accused him of perfidy; but in the present instance he seems to have been ruled by his own officers, with whom it is said that his rapid promotion on exchanging the land for the naval service made him unpopular. Having refitted, he sailed for the West Indies, where he failed in an effort to take Saint Lucia, but made himself master of the islands of Saint Vincent and Grenada, and had an indecisive engagement with Admiral Byron. In Sept. 1779, he appeared off Savannah with the purpose of acting against that city in concert with Gen. Lincoln; but having first lost a favorable opportunity for attack by giving the British time to complete their defences under cover of a truce, he next ruined the enterprise by a precipitate assault when he should have besieged in form. In this action Pulaski was killed, and D'Estaing was wounded in the arm. He returned to France in 1780, was a member of the assembly of notables in 1787, was chosen commandant of the national guard of Versailles in 1789, and afterward went to reside in Paris, where he enrolled himself as a private in the national guard. He gave in his submission to the assembly after the flight of the king, was made admiral and put on the retired list in 1792, but falling under the suspicion of the terrorists, was finally led to the guillotine.

ESTATE (Lat. *status*), in law, a term usually expressing an interest in lands, though in a general sense it is applied to both real and personal property, as we sometimes see in wills and the like. But when used with a discriminative signification to designate the nature and limit of the interest, it properly relates to lands only. We shall in this article merely define the several classes of estates, without going into an extended illustration of their legal incidents. I. An estate of inheritance, which is sometimes expressed by the term fee. Thus when we say a man has the fee of lands, it is meant that he has an inheritable estate; and in the United

States, where there is no limitation to particular heirs, it is understood to be the entire proprietorship of the lands. But in England there are estates of inheritance in fee simple and fee tail, the former being an estate which descends to a man's general heirs, the latter being limited to certain specified heirs, as for instance to a man's issue male or female, or to the heirs of his body begotten of a certain wife. By such limitations, although the estate descends to the particular heirs, yet failing them it reverts to the grantor or supposed original proprietor, instead of descending to a man's general heirs; and so far there is an obstruction in the enjoyment of the estate, because a man is perpetuated in and represented by his heirs. In this sense a fee simple is deemed an absolute ownership, in distinction from a fee tail, which is limited in descent. Another distinction, however, was more important, viz.: that while the former could be conveyed or devised, the latter in theory could not be, yet practically it could be alienated by a particular form of proceeding called a common recovery. Yet a fee simple is not necessarily the entire proprietorship, for it may be subject to encumbrances by mortgage or judgment and otherwise; and smaller estates, as a lease for years, may be carved out of it, though in such case it would be more proper to call the principal estate a fee simple in reversion or remainder. There are also qualified or determinable estates of inheritance, by which is meant that the estate may be determined by some contingency, and yet the contingency may never happen, and therefore by possibility the estate will be perpetual. The illustrations of this species of inheritance are for the most part hypothetical, as to a man and his heirs so long as St. Paul's church shall stand. Sometimes the qualification is residence in a particular place. Or again, there may be a restriction that the person taking the estate shall not marry, an instance of which we have in the case of a devise by a man to his wife on condition that she shall continue a widow. When by the limitation an estate is to last till a certain event, there is until the event happen an inheritance subject to being determined; though if the event become impossible, then the estate is converted into a fee simple absolute. A conveyance by the owner of a determinable fee will of course be subject to the qualification or contingency upon which the estate depends. It may be a question, in the case of a limitation to a man and his heirs so long as they reside in a certain place, what the effect of alienation would be; but probably the same rule would apply, viz.: that it would be valid to the extent of the right which the grantee himself had, but would be defeated by a breach of the condition. If this would be inconsistent with the nature of the estate, the restriction would, it may be presumed, be void under the statutory rule which has been adopted in the state of New York, whereby the power of alienation cannot be suspended by any limitation or condition whatever

for a longer period than two lives in being at the creation of the estate. II. An estate for life. This may be either by express grant or by operation of law. Of the latter kind are dower and curtesy, the respective interests of the wife and husband, each in the lands of the other, in case of survivorship. Estates for life as well as inheritance are included in the common denomination of freehold (*liberum tenementum*); which term seems to have been derived from the ancient mode of conveyance, which was by livery of seisin, that is, delivery of possession according to the form of feudal investiture. Other estates which were of an inferior nature could be transferred without this formality. It was chiefly, however, as a distinction from copyhold estates that the term was used. The copyhold was originally an estate at the mere will of the lord, but became established by prescription, the evidence of which was in the rolls of the courts baron, whence the estate was said to be held by copy of court roll; and although it thus became independent of the will of the lord, it was still deemed a base tenure, and the form of conveyance was by surrender to the lord, and a new grant by him to the alienee, admitting him to be tenant of the copyhold upon the same terms by which the estate had been formerly held. An estate for life may be either for the life of the tenant himself or of another person. The latter is usually designated as an estate *par autre vie*. III. Estates less than freehold are for a term of years, or at will, or by sufferance. The first is for a definite period; but whatever may be the length of the period, even if it should be a thousand years, it is still inferior to a freehold, and is classed in law with chattel interests. Thus, upon the death of the tenant, his lease is included with the personal property to be administered as assets, instead of going to the heir. In the state of New York, by statute, leases for a term of years are denominated chattels real; they are made subject to the lien of a judgment, but are to be administered as personal estate by an executor or administrator. An estate held by the deceased for the life of another person is included under the same rules. An estate at will was when lands were occupied by the tenant with consent of the landlord, but without any agreement as to the time the tenant should be permitted to remain. It can hardly be said to exist at present, as the courts now hold a tenancy where no certain term is agreed upon to be from year to year, and reasonable notice must be given of the intention to terminate it. The circumstance that distinguishes the two kinds of tenancy is the reservation of a certain rent, which may be either by express agreement, or by implication from the receipt of rent. If a certain rent is payable, it constitutes an estate from year to year; but if neither rent nor time of occupation be specified, it would be a tenancy at will. An estate by sufferance is where the tenant has been in possession by lawful title, but wrongfully holds

over after the determination of his interest. In such a case the tenant holds by the mere laches of the landlord, and is subject to being turned out by summary proceedings. But any act of the landlord affirming the wrongful holding, as receipt of rent, would convert the naked occupancy into a tenancy from year to year, and is then determinable only at the end of the year. One month's notice to quit is required by statute in New York before taking summary proceedings; but 6 months' notice is necessary to enable the landlord to proceed by action of ejectment. The English statute of frauds (29 Charles II.), which has been generally reenacted in the United States, requires leases for a term of more than one year to be in writing; and in the state of New York a lease for a term exceeding 3 years must be recorded, or it will be inoperative against subsequent *bona fide* purchasers. Another distinction in the nature of estates has reference to the time when the right is reducible to possession. The right may exist prospectively, and it is then termed an estate in expectancy. It is of two kinds: one created by the act of parties, and called a remainder; the other by operation of law, and called a reversion. An estate in remainder is what remains after a particular estate, either for years or life, to take effect in possession immediately after such estate, and must be created at the same time, though limited to commence in possession at a future time. Thus if a life estate be granted to A, with remainder to B for life, and remainder to C in fee, here are two remainders to commence in future, and the whole property constitutes but one estate. Yet in ordinary phraseology, where there is but one remainder including the whole residue of the estate, the fee is said to be in the person to whom such limitation is made. An estate in reversion is the residue of an estate left in the grantor or his heirs or in the heirs of a testator after the determination of a particular estate granted or devised. The estate reverts by operation of law, and a reservation to the grantor by the deed would have no effect, being only what the law itself prescribes. A contingent remainder is when the limitation depends upon a contingency which is uncertain or may not occur after the determination of the particular estate; though it is held that such contingency must not be a remote possibility, as if the limitation should be to the heirs of a child not yet born. A single illustration of this kind of estate will be sufficient. If a grant be made to A for life, with remainder to the heirs of B, and B should survive A, inasmuch as he cannot have heirs while living, the remainder would fail; but if the limitation be to A and B during their joint lives, with remainder to the survivor, here the remainder will take effect, though it is uncertain as to the person who will have the benefit of it. An executory devise is a disposition of an estate by will which would not be valid if made by deed, as a limitation of a contingent remainder. The distinction is that

the remainder must take effect immediately upon the determination of the particular estate or not at all; whereas an executory devise is good without a particular estate to support it. Thus if a devise be made to A, to take effect on his marriage, in this case until such marriage the fee descends to the heir at law, subject to being divested by the performance of the condition. There is still another distinction of estates growing out of the nature of the possession, under which head are classed joint tenancy, tenancy in common, and coparcenary. The last of these, which is a descent of an inheritance to female heirs, in which case they take an equal interest in the entire estate, but without being subject to the rule which applied to joint tenancy as to the right of the survivor to the whole, does not exist in the United States, at least is not distinguishable from a tenancy in common. By statute the descent of lands is to all the children, male and female, who hold as tenants in common. So joint tenancy, the peculiar feature of which is that the whole estate vests in the survivor, has been abolished in this country, except in respect to executors and other trustees, and except also when it is expressly declared in the deed or will creating the estate that it is to be held in joint tenancy. In all other cases, where there is a possession of lands by several persons without any separation into specific parts, it is a tenancy in common; and it is not necessary that they should all hold by the same title, or have an equal interest; it is sufficient if each has an interest, and that it is undivided. Such an interest can be conveyed or devised, the same as property held in severalty, and partition may be compelled by either party on application to a competent court. Various equitable interests in lands will be discussed in the article TRUSTS. —We have thus far considered estates of a corporeal nature only; but there are also incorporeal estates, such as rents, easements, &c. But the general principles applicable to the one class will also apply to the other; and whatever there may be peculiar to any particular species of incorporeal estate will be treated under the appropriate head.

ESTE, a princely house of Italy, from which several European dynasties are descended. Its genealogy is conflicting until the 9th century, from which period it is traceable to the petty princes who held Tuscany and other Italian states as imperial fiefs under the Carolingian emperors. The name of Este was derived from the castle and town of Este (anc. *Ateste*), 15 m. from Padua, formerly a Roman colony of some note, and now a town of about 9,000 inhabitants in the Venetian delegation of Padua. The more immediate founder of the house was Alberto Azzo II. (born 996, died 1097). By judicious management and by grants from the emperor of Germany he added to the fiefs and manors which he had inherited from his father and uncle until they reached the number of about 80, including the margraviate or marquisate of

Este. By his sons Guelfo IV. (Welf) and Folco I., the Este family was divided into two great German and Italian branches. Guelfo IV. was Alberto Azzo's eldest son by his first wife, Kunitza or Kunigunde, a Bavarian princess of the German house of Welf, who counted their ancestry back to the times of Charlemagne. He inherited from his uncle the duchy of Carinthia and the march of Verona, and succeeded to the dukedom of Bavaria in 1071. Through his descendants, the Bavarian dukes, Henry the Proud and Henry the Lion, he became the progenitor of the elder or German branch of the house of Este, from which the lines of Brunswick and Hanover (known also by the name of Este-Guelph) and the reigning dynasty of England are descended. Folco I. (1060–1135), one of Alberto Azzo's sons by his 2d wife Garsenda, heiress of the counts of Maine in France, became the founder of the principal younger or Italian branch of the house, from whence came the former dukes of Ferrara and the present dukes of Modena. Folco I. was succeeded as marquis of Este by his son Ubizzo (died in 1190), who was confirmed in all his possessions by the emperor of Germany (1184), and appointed marquis or imperial vicar of Milan and Genoa. The foundation of their influence in Ferrara was laid in the 12th century by the marriage of a marquis of Este with Marchesella, the last offspring of the Adelardi family, the popular leaders of the Guelphs against the powerful Ghibelline family Taurello. This marriage secured to the Este family a great political influence, and the possession of Ferrara and of other important Italian towns. Azzo VI. (1170–1212) was placed in 1208 at the head of the government of Ferrara with power to appoint his successor. He was the leader of the Guelphs against Ezzelino, the champion of the Ghibellines. Azzo VII. (1205–1264) defeated Ezzelino, and was hailed as the saviour of Lombardy. Ubizzo III. and Nicolo I., sons and successors of Aldobrandino II., took possession of Modena, May 13, 1336. Their brother Rinaldo died during the siege of that city, Dec. 31, 1335; Nicolo died May 1, 1346, and Ubizzo in May, 1352. The titles of duke of Modena and Reggio and of Ferrara were formally conferred upon the marquis Borso of Este (died in 1471), the former in 1452 by the emperor of Germany, and the latter at a subsequent period by Paul II., who held Ferrara as a papal fief. Borso and many of the succeeding dukes were distinguished for their patronage of art and letters. Ercole I. (1433–1505) was the friend of the poet Boiardo or Bojardo, who was often employed in his service. Among the distinguished visitors of his brilliant court was the youthful Ariosto, who afterward became the protégé of Ercole's sons, Cardinal Ippolito of Este (1479–1520) and Alfonso I., the husband of Lucrezia Borgia (1486–1534), who succeeded his father as duke of Ferrara and Modena. This cardinal of Este was the same prelate who became so jealous of his natural brother Giulio that he was accused of having caused him to be

blinded. He must not be confounded with his nephew, Cardinal Ippolito of Este, the younger, a brother of Alfonso's successor, Ercole II. (1508-1519), who built the Estensian villa at Tivoli near Rome. Ercole II. was succeeded by Alfonso II., who was the last legitimate prince of the house of Este, whose court was renowned for its splendor, and whose name, as well as those of his sisters Lucrezia and especially Eleonora, are associated with the misfortunes of the poet Torquato Tasso. The power of the Este family in Ferrara expired with Alfonso II., who died in 1597. His nephew Cesare (a natural son of Alfonso I.) succeeded him, but Ferrara was seized by Clement VIII. as a papal fief. Cesare was compelled to evacuate the city, Jan. 28, 1598, but retained the duchies of Modena and Reggio. These duchies were taken by Napoleon I. in 1797 from the duke Ercole Rinaldo (1727-1803), and annexed to the Cisalpine republic. The male line expired with him, and his only daughter Maria Beatrice (1752-1829), the last offspring of the Italian branch of the house of Este, married the archduke Ferdinand, 3d son of Francis I. of Austria, who became the founder of the family of Austria-Este. The possessions of Massa Carrara were inherited by her oldest son Francis IV. (1779-1846), who was reinstated as duke of Modena in 1814, and was succeeded by Francis V., archduke of Austria-Este, who was duke of Modena in May, 1859, when war broke out between Austria and France and Sardinia. The name of Este was adopted by the children of the duke of Sussex (1774-1843) and Lady Augusta Murray de Ameland (died in Rome, March 5, 1830). The marriage of the duke with Lady Murray having been deemed a violation of the royal marriage act passed in the reign of George III., it was annulled by the prerogative court and dissolved in Aug. 1794. Their daughter, Augusta Emma d'Este, was married in 1845 to Sir Thomas Wilde (afterward Baron Truro), who died Nov. 11, 1855. Their son, Augustus Frederic d'Este, a colonel in the army, born Jan. 13, 1794, died in Dec. 1848. After the death of William IV. he claimed his recognition as a member of the royal family, but the Hanoverian council of state, to whom he submitted his claim in 1834, refused to take it into consideration. After the death of his father his claims to the dukedom of Sussex were disallowed by the house of lords (July 9, 1844).

ESTERHÁZY (or **ESZTERHÁZY**) OF **GALANTHA**, a noble Hungarian family, who trace their origin to the 10th century, though there is no authentic record of their existence till the 13th. The oldest branch of the family were created in 1622 counts of Forchtenstein (Hung. Fraknó), and afterward princes of the empire. Among its eminent members were Paul (Hun. Pal) IV. (1635-1713), palatine of Hungary, who contributed among others to the deliverance of Vienna in 1683; Nicholas (Miklós) III. (1740-1790), who was a zealous patron of science and art, especially of music, Haydn the composer having been his chapel master for 30 years;

and Nicholas (Miklós) IV. (1765-1833), distinguished as a diplomatist and as the founder of a splendid picture gallery at Vienna. It is said that the crown of Hungary was offered to him by Napoleon in 1809, but that he declined it.—**PAUL ANTHONY** (**PÁL ANTAL**), son of the preceding, born March 10, 1786, officiated as Austrian ambassador at various courts of Europe, and for several years at that of St. James, where he lived in a magnificent style. In 1849 he occupied for a few months a seat in the Hungarian ministry under Count Louis Batthyány, retiring as soon as it became evident that the political independence of Hungary was not possible without a rupture with Austria. He is the present representative of the oldest branch of the Esterházy family, and the most extensive landholder in the Austrian empire; his possessions comprising manors, chateaux, villages, and estates in Hungary, amounting to hundreds. Beside these he owns the manors of Pottenstein and Schwarzbach in Lower Austria, Gailingen in Baden, and Edelstetten in Bavaria. The central administration of his Hungarian possessions is at Eisenstadt, a town 12 m. from Oedenburg which contains a magnificent palace. In the park is an orangery with 400 orange trees and numerous other species of exotic plants. North of the town are the princely zoological gardens. Other celebrated palaces of the prince are in the village of Esterház (Lower Hungary, circle of Oedenburg on the lake of Neusiedl) and at Vienna. The heir to his title and estates is his son **NICHOLAS**, born June 25, 1817; married in 1842 a daughter of the earl of Jersey, who died Nov. 17, 1853.—**Count VALENTINE** (**VALENTIN**), a member of the Lanschitz branch of the Esterházy family, born Jan. 28, 1814, was Austrian ambassador in Stockholm, in Munich, and from 1854 to 1855 in St. Petersburg. During the Crimean war he was deputed (Dec. 28, 1855) by the Austrian court to propose terms of peace to the Russian government, which were accepted Jan. 11, 1856.

ESTHER (Heb. *Hadasa*), the name of a Persian queen of Jewish descent, wife of Absuerns, and also the title of the Biblical book that contains her history, and the interesting narrative of the delivery of the Jews by her from a general massacre that was to take place on the 13th of the month Adar, throughout the whole Persian empire. The book is one of the smallest historical works of the Hebrew Scriptures, and one of the 5 so called *Megillot*, and belongs to the Hagiographa. It is written in remarkably correct, but somewhat modern Hebrew, and distinguished by some new words, and the total absence of any reference to God, notwithstanding the decidedly providential though not unnatural, concatenation of the events related. It is chiefly this circumstance which has led to the conclusion of some critics that the book is a translation of, or extract from, a Persian chronicle, though its authorship has also been attributed to Ezra, Mordecai, and other distinguished Jews. The book narrates how the king, incited by his vindictive minis-

ter Haman, who was incensed by the independent spirit of the Jew Mordecai, resolved upon the massacre of all the Jews in his dominions, but was turned from his wicked purpose by Esther, who, inspired by Mordecai, saved her nation at the risk of her own life. To commemorate the almost miraculous salvation of their people, and the destruction of their enemies, Mordecai and Esther introduced the fast of the 13th of Adar, the day of danger, and the festival of Purim or lots, still celebrated by the Jews on the 14th and 15th of the same month, as days of entertainment and joy, and for sending presents to each other, and alms to the poor. On the former of these days the *Megillah* is read in the synagogues. The Persian name of the queen has been differently translated; and that of the king Ahasuerus, "who reigned from India to Æthiopia over the 127 provinces of the empire of Persia and Media," is a source of contradictory hypotheses among critics. From the last king of Media down to the last king of Persia, each monarch of that united empire has had his advocate. The claims of Xerxes, the mighty, luxurious, and fickle invader of Greece, are best supported by his character; those of Artaxerxes Longimanus, by the authority of the Septuagint and Josephus. The apocryphal additions to the book caused it to be violently attacked by Luther.—By a singular coincidence, another Jewess Esther also attracted the love of a mighty gentile king, Casimir the Great of Poland (1333–1370), became his mistress, and caused a great deal of good to her people, in a time of most barbarous persecutions. Her history has been adorned by the romantic pen of Bernatowicz, Bulgarin, Bronikowski, Jósika, and others; and her memory is preserved by the tomb of Lobzów, near Cracow, once her residence.

ESTHONIA (Ger. *Esthland*; Esth. *Wiroma*), a government of European Russia, extending along the S. side of the gulf of Finland, having the Baltic sea on the W., the government of Livonia and Lake Peipus on the S., and the government of St. Petersburg on the E., and including Dago and some smaller islands in the Baltic; area, 7,993 sq. m.; pop. about 320,000, consisting chiefly of Esthonians (formerly called by the Russians *Tchuds*), but including also many Russians, Germans, Swedes, and Danes. Its capital is Revel, which name is also often given to the whole government. The surface is generally low, sandy, rocky, or marshy, and is interspersed with more than 200 lakes, but produces abundantly grains, flax, and pulse. There are many extensive forests of firs and birches. The climate is moist, cold, and salubrious; the winter continues for 8 months, and the transition to summer is sudden. The fisheries are productive, agriculture receives great attention, and the rearing of cattle, and particularly of sheep of the merino and Saxon breeds, is an important interest. Lutheranism is the prevalent religion, but there are also many adherents of the Greek church. The government of Esthonia is divided into 6 districts, Revel, Hapsal, Weissenstein,

Wesenberg, Leal, and Kunda. Its governor is under the orders of a governor-general who resides at Riga, and who has authority also over Livonia and Courland.—The Esthonians are of Finnish descent, of slight stature, daring, and vindictive. They embraced Christianity about the beginning of the 13th century, and fell successively under the power of the merchants of Bremen, the Danes, the Teutonic knights, the Livonian knights (*Porte Glaive*), and the bishops of Riga and Ungannia. Threatened in 1555 with conquest by Russia, they preferred to recognize the authority of Eric XIV., king of Sweden, whose successors gave legal sanction to the rights of the Esthonians by various treaties, especially by that of Oliva in 1660. In 1710 the country was conquered by Peter the Great in his war with Charles XII., and was definitely confirmed to Russia by the treaty of Nystadt in 1721. The population was from that time kept in the grossest ignorance and degradation, living with their cattle in miserable huts, the doors of which served also for windows and chimneys. Attempts for their emancipation were made by Alexander I. in 1816, who founded schools among them. The Esthonian lords are chiefly of the German race, and to their efforts the ameliorations are to be attributed. There are Esthonian popular songs, of a naïve and melancholy character, versified in the Finnish manner, that is, metrically and alliteratively. The oldest of these is a song of the peasants of the canton of Revel, which has been sung from the time of the introduction of Christianity.

ESTIENNE, or ÉTIENNE, a celebrated French family of printers. See STEPHENS.

ESTILL, an E. co. of Ky., intersected by the Kentucky river; area about 300 sq. m.; pop. in 1850, 5,985, of whom 411 were slaves. It is well supplied with water power, and rich in coal and iron. The surface is uneven or mountainous, and there are many extensive forests. The soil, which is moderately but not uniformly fertile, is suitable for the production of grass and various kinds of grain, and in 1850 yielded 291,728 bushels of Indian corn, 18,629 of oats, and 24,150 lbs. of tobacco. There were 10 churches, and 215 pupils attending public schools. This county was formed in 1808, and named in honor of Capt. James Estill, who fell in an engagement with the Indians in 1782. Capital, Irvine.

ESTOVERS, a Norman term, equivalent to necessities. The most ordinary use of it was in reference to the right of a tenant of lands to take wood necessary for domestic or farming purposes. In such case it was an exclusive right, and related to wood upon the leased premises. But there could be also common of estovers, that is to say, a right of taking wood from other lands, either in common with other persons, or it might be an exclusive privilege appendant to a particular tenement. The alimony of a wife who had obtained a divorce *a mensa et thoro* was formerly called estovers, and could be recovered by a writ *de estoveriis habendis*.

ESTRAYS, or STRAYS, domestic animals,

usually designated as cattle, which are found wandering in enclosed lands, and the owner of which is unknown. In England they belong to the proprietor of the manor on which they are found, provided that after proclamation in the church and two market towns the owner does not appear to claim them within a year and a day. In the old books estrays were described as *pecus vagans, quod nullus petit, sequitur, vel adlocat*; therefore dogs and cats were not included; a swan might be, but no other fowl. In New York, estrays, which by statute are neat cattle, horses, and sheep, found in enclosed grounds between the months of November and April, may be sold by the owner of such grounds who shall have taken up such estrays, upon a certain notice to the town clerk; the proceeds, after paying the expenses of keeping and of sale, to be paid over to the supervisor for the use of the town unless the owner shall claim the same within a year after the sale. The limitation to that particular period of the year is probably because at other times cattle are often at large, and find sufficient sustenance by the roadside or upon common lands. In case of damage done by cattle in enclosed lands, a different remedy is provided, viz., by putting them in a pound, and a sale by the pound master to pay such damages and the expenses of keeping, unless the owner shall appear and settle the same within 6 days. So where cattle are at large contrary to village or town regulations, the ordinary proceeding is to put them in a pound, and after a certain time to sell them for the payment of the penalty and charges.

ESTREAT (Lat. *extractum*; Fr. *estrete*), a term still in use in criminal proceedings, by which is signified the extracting or taking out a record of a court for the purpose of being prosecuted in another court, or it may be in the same court. To estreat a recognizance is to endorse it by order of the court for prosecution. The use of the term probably grew out of the custom in England of sending all recognizances to the court of exchequer to be prosecuted.

ESTRÉES, GABRIELLE D', mistress of Henry IV. of France, born in 1571, died April 10, 1599. In 1590 she met Henry for the first time at the chateau of Cœuvres, where she resided with her family. She was fair and of singularly delicate complexion; her eyes were blue, and combined in a remarkable degree tenderness with brilliancy of expression; her hair had a golden hue, her forehead was bold and large, her whole presence was beaming with intelligence and instinct with gentleness and grace. She inspired the French monarch with a violent passion, which, however, did not interrupt her relation with her old lover, the duke of Bellegarde. The king caused her to take M. de Liancourt for her nominal husband, and subsequently raised her to the rank of marchioness of Monceaux, and in 1595 to that of duchess of Beaufort. At the same time he lavished riches upon her in great profusion, and at the time of her death she was the owner of more than 12 estates, some of which are to this day pointed out in the vicinity of Paris. The ex-

travagance of frivolous ladies of our days dwindles into insignificance compared to the fabulous display of Gabrielle on all public occasions. Henry would have divorced himself (as he afterward did) from Margaret of Valois, his legitimate wife, for the purpose of raising Gabrielle to the throne of France, if it had not been for his minister and friend Sally, who was the only person with whose influence she was unable to cope. She had 3 children by the king, 2 sons and a daughter.

ESTREMADURA, a province of Portugal, on the W. side of the kingdom, between Duero, Beira, Alentejo, and the Atlantic ocean; area, 7,256 sq. m.; pop. 806,000. It contains the cities of Lisbon and Leiria. Its soil is watered and fertilized by numerous streams, the principal of which are the Tagus and the Soldao. Grains, fruits, and wines are produced. It has suffered from earthquakes, and has unexplored mines.

ESTREMADURA, an old province of Spain, in the W. part of the peninsula, comprising the modern provinces of Badajoz and Cáceres, bounded N. by the province of Salamanca E. by those of Toledo, Ciudad Real, and Cordova, S. by those of Seville and Huelva, and W. by Portugal; area, 14,742 sq. m.; pop. 601,124. It is entirely surrounded by mountains, and is divided naturally into 3 parts by the rivers Tagus and Guadiana, and into 2 parts by the mountains of Guadalupe, San Pedro, and San Mamed. These mountains, forming but a single chain, traverse the province from E. to W. and form the boundary between its two present divisions. The soil of Estremadura is very fertile, and if well cultivated would produce sufficient to support a third of the population of Spain; but nearly all the large proprietors reserve their lands for the pasturing of their flocks, so that the agricultural products are few. A little barley and wheat are cultivated, and chestnuts are abundant, and are the principal food of the inhabitants. This province is distant from the sea, and has no great highways. Even its rivers are little used for navigation. Its manufactures are of no importance, and it has neglected mines of lead, silver, and coal. It was formerly a part of the kingdom of Leon, and was the last province conquered by Alfonso IX. of that kingdom; whence the name of Estremadura, from *extrema ora*, last region.

ESZEK, ESSECK, or ESSEG (Hun. *Esék*), a town and fortress of Austria, capital of Slavonia, and of a circle of its own name, on the river Drave, 13 m. from its confluence with the Danube; pop. 12,600. It is the centre of the commerce and industry of Slavonia. Fairs for cattle, corn, and other produce are held here 4 times a year. The Drave has been made available for steamboat navigation within the last few years. There are 1 Catholic and 3 Greek churches and other public institutions and buildings. The fortress contains an arsenal and barracks for 30,000 men. During the revolutionary period of 1848-'49, the fortress was occupied by the Hungarians until Feb. 14, 1849, when it surrendered to the

Austrian Gen. Trebersberg. Not far from Eszek stand the famous bridges constructed by Solyman in 1566, to facilitate the entrance of the Turkish armies into Hungary. The town was a colony of the Romans, who called it Mursia.

ÉTAMPES (anc. *Stampæ*), an ancient French town in the department of Seine-et-Oise, 34 m. by rail from Paris; pop. in 1856, 7,947. It is situated on 2 small tributaries of the Juine, or Étampes, in a fertile valley, and is surrounded with shady promenades. Near the railway station to Paris is a ruined tower called Guinette, the only remnant of the ancient castle built by King Robert in the 11th century. There are several fine churches, a town hall, and a castle which is said to have been given in appanage to the duchess d'Étampes and other royal favorites. The chief manufactures are soap, leather, counterpanes, woollen yarn, and hosiery. There is a considerable trade in wool, corn, honey, and flour, and more than 40 mills.

ÉTAMPES, ANNE DE PISSELEU, duchess d', a mistress of Francis I. of France, born in 1508, died about 1576. Her father, Guillaume de Pisseleu, was a country gentleman of Picardy, who was married 3 times, and had no fewer than 30 children. Anne was a maid of honor of the queen regent, when she attracted the attention of her son Francis I. She became his favorite mistress, displacing the countess de Chateaubriant; but to save appearances he gave her for a nominal husband Jean de Brosse, afterward duke d'Étampes. The new duchess secured lucrative appointments to her relatives and friends, and wielded a paramount influence in the affairs of the nation. Upon the fine arts and in some other directions she exerted a good influence, but the jealousy which sprung up between her and Diana of Poitiers, the mistress of the dauphin Henry, eventually became a source of calamity for her lover and for France. It was chiefly under the influence of this feeling that she betrayed to Charles V. the movements of the French army; and the disadvantageous treaty of Crécy in 1544 was due to the intrigues of Anne and of Diana. Anne was present in 1538 at the interview between Francis I. and Charles V., and, according to the gossiping chroniclers of the times, even the stern emperor was fascinated by her beauty. The death of Francis (1547) proved fatal to her power. Henry II. banished her from the court, and she ended her days on one of her estates. It is said that she here devoted herself to religion, and that she became a convert to Protestantism.

ETAWAH, a district of British India, in the lieutenant-governorship of the N. W. provinces, bounded N. by Minpooree and Furruckabad, E. by Cawnpore, S. by Bundelcund, S. W. by Gwalior, and W. by Agra; area, 1,674 sq. m.; pop. in 1853, 610,965, of whom 578,158 were Hindoos. It lies chiefly in the Doab between the Jumna and Ganges, but comprises also a narrow tract on the right or S. W. bank of the former river. The climate from October to March is delightful, and fires are needed at

night; but in the spring, from the unsheltered character of the country, the hot winds blow with a fury unsurpassed in any part of India. They are succeeded by a wet season, in which the rain falls in torrents. The principal crops are indigo, cotton, opium, sugar cane, rice, wheat, barley, various European vegetables, and fruits. Timber is very scarce. The district was formerly noted as the haunt of numerous bodies of Thugs, who infested both sides of the Jumna, and were not unfrequently protected by the native landowners. To so great an extent did the system of thuggee prevail, that in one year (1808) 67 dead bodies were taken out of wells in this district. Etawah was acquired by the British in 1801 in lieu of a subsidy claimed from the nabob of Oude. It was formerly united with Cawnpore, but in 1840 was erected into a separate zillah.—ETAWAH, the principal town of the above district, is situated on high ground about 1 m. from the left bank of the Jumna, 100 m. N. W. of Cawnpore, and 73 m. S. E. of Agra; pop. 23,300. Ghats, or flights of steps, some in ruins, others new and frequented by Hindoo devotees for the purpose of religious ablutions, lead toward the river, across which is a ferry and at times a bridge of boats. A fort and a large gaol are the principal buildings. The town was a prosperous and important place under the Mogul empire, but is now little more than a mass of ruins, and is generally described as one of the least attractive stations in India. It owes some commercial consequence to its position at the junction of the roads from Calpee and Cawnpore to Agra, and has a few bungalows and other military buildings. A detachment of the 9th regiment Bengal native infantry mutinied here in the latter part of May, 1857.

ETCHING. See ENGRAVING.

ETEOCLES AND POLYNICES, mythical kings of Grecian Thebes, sons of Œdipus and Jocaste. After the flight of their father, the brothers agreed to govern the kingdom alternately; but Eteocles refusing, on the expiration of his term, to surrender the sceptre, Polynices retired to the court of Adrastus, king of Argos, who gave him one of his daughters in marriage, and undertook to sustain him in the enforcement of his rights. Organizing accordingly that confederacy of Peloponnesian chiefs, whose exploits Æschylus has immortalized, Adrastus with his son-in-law marched against Thebes. The success of the belligerents was various, and many warriors were slain, when the brothers, to prevent the further effusion of blood, resolved to decide the contest by single combat, in which both perished.

ETESIAN WINDS (Gr. *ετησιαί*, from *eros*, year), the name given by the ancients to the N. E. trade winds which blow for about 6 weeks during the summer throughout the countries adjacent to the Mediterranean, especially its eastern portion. On the sea they are called by the fishermen *meltem*, probably from *mal temps*, in reference to the fury with which they

blow, and the dangerous weather they create for their small craft. On land they are more favorably regarded, Cicero remarking of them that in Italy they are equally comfortable and salutary to men, beasts, and birds, and likewise beneficial to vegetation, by moderating the violent heat of the weather during the season of the dog days. Pliny and Seneca also make mention of them. In the Levant they commence toward the middle of July about 9 in the morning, continuing only in the daytime. The sun at that season is powerfully heating the surface under the tropic of Cancer, and rarefying the atmosphere south of the Mediterranean. Currents of air are thus drawn in over the desert of Sahara; but though in their passage across the Mediterranean they must become charged with moisture, the clouds are dispersed as they pass the margin of the hot sands, and the vapor dissipated in the rarefied air is swept on, to be again collected together and precipitated in a cooler region.

ETHELBALD, king of Wessex, son of Ethelwulf, king of the Anglo-Saxons, obtained the throne of Wessex in 856, died in 860. While Ethelwulf was making a journey to Rome, on his way back from which he married Judith, the young daughter of the French monarch, Ethelbald formed the project of seizing the throne. A civil war was prevented only by the moderation of Ethelwulf, who resigned to his son the dominion of Wessex, and confirmed that portion of the kingdom to him in his will. The reign of Ethelbald was peaceful, but he excited general disapprobation by marrying, contrary to the canonical law, his stepmother Judith. Ecclesiastical and popular displeasure forced him at length to a separation, and Judith returning to France eloped from a convent with Baldwin, afterward count of Flanders. From this union descended Matilda, wife of William the Conqueror, and through her the race of English sovereigns.

ETHELBERT, king of Kent, and 3d bretwalda or chief of the Anglo-Saxon heptarchy, born about 545, ascended the throne in 560, died in 616. As the representative of Hengist, he claimed superiority among the Saxon states, but was twice discomfited in battle in the early part of his reign by Ceawlin, the powerful king of Wessex. About 589, however, he had acquired the dignity of bretwalda, Ceawlin being deposed, and dying a few years later. The most remarkable event of his reign was the introduction of the Christian religion into Britain. His queen Bertha, a daughter of Charibert, king of Paris, professed this faith, and her virtues and popularity recommended it both to the king and the people. Nor could it be unknown to the English Saxons that Christianity had already become the religion of their brethren who had descended as conquerors toward the south of Europe. In 596, 40 Italian and French monks, sent by Gregory the Great, under the conduct of Augustin, landed on the isle of Thanet. They were received by the king beneath an oak, the

sacred tree of the druids, where it was supposed any magical spell would be without influence; and after a conference he gave them permission to preach without molestation, though he himself had no inclination to abandon the gods of his fathers. The queen prepared a residence for the new apostles, and in 597 Ethelbert received the sacrament of baptism, and his example was followed by 10,000 of his subjects. About 600 he issued the earliest remaining code of Anglo-Saxon laws, consisting of 89 enactments, relating principally to the amount of pecuniary fines payable for various transgressions.

ETHELBERT, 3d king of the Anglo-Saxons, son and successor of Ethelwulf, died in 865. He inherited, in 857, the government of all the kingdom, excepting Wessex, and upon the death of his brother Ethelbald in 860 possessed himself also of that portion. His reign was molested by the invasions of the Northmen, who sacked the city of Winchester, landed on the isle of Thanet, pillaged a part of Kent, and made their appearance in Northumbria under Ragner Lodbrog.

ETHELRED (also written EDELEED and ETHERED) I., 4th king of the Anglo-Saxons, son of Ethelwulf, and successor of Ethelbert, ascended the throne in 866, died in 871. His reign was a continuous struggle against the Northmen. The sons of the Danish chieftain Ragnar, whom the Northumbrians had put to death, appeared in East Anglia, afterward took possession of the city of York, and defeated and slew two Northumbrian princes who attempted to recover it. Marching S. they took up their winter quarters at Nottingham, whence they retired without a battle after being for some time beleaguered by Ethelred and his brother Alfred. Passing into East Anglia, they burnt on their way the monasteries of Bardney, Croyland, and Medeshamstede, ravaged the nunnery of Ely, and seized and murdered the East Anglian king Edmund, who was hence revered as a martyr by his subjects and their posterity. They were met in 871 by Ethelred and Alfred at Reading, but were able to maintain their ground. Being, however, 4 days later, at Ecsodune, attacked with great impetuosity by Alfred, they were routed and were pursued for a night and a day. Within a fortnight another battle was fought at Basing in which the invaders were victorious, and an obstinate engagement soon followed at Merton. Ethelred died of a wound, and left to Alfred the inheritance of his cares.

ETHELRED II., surnamed the Unready, king of the Anglo-Saxons, son of Edgar, successor of Edward the Martyr, born in 968, ascended the throne in 978, died in London, April 23, 1016. His reign was long, and the most unfortunate in Anglo-Saxon history. The son of that Efrida whose criminal ambition had caused the tragic death of the late king, he never possessed the affections of his subjects, and was acknowledged king only because there was no other prince of the royal blood. The Northmen made

several invasions, appeared with a formidable armament in 991 off the coast of Essex, and were met at Maldon by Brithnoth, earldorman of that country, who after having foiled their efforts for 14 days was defeated and slain. The king, listening to the advice of Siric, archbishop of Canterbury, and of many of the degenerate nobility, purchased the departure of the enemy from the kingdom by paying them 10,000 pounds of silver. A fleet fitted out against them was rendered useless by the treachery of Elfric. In 993 the Danes were joined by 3 chieftains who were sent to oppose them, and then captured the castle of Bamborough and ravaged both sides of the Humber. In 994 the Northmen, under the command of Sweyn, king of Denmark, and Olave, king of Norway, dared to attack the centre of the kingdom, sailed up the Thames, laid siege to London, from which being repulsed, they plundered Essex, Sussex, and Hampshire, and having obtained horses were spreading devastation far into the inland counties. The forbearance of the invaders was now purchased by the payment of 16,000 pounds, and in 1001 of 24,000 pounds of silver. Ethelred and his advisers then determined to rid themselves of the Danes by a general massacre of all of them who were remaining in the kingdom. Secret orders were sent to every town and county, and on Nov. 13, 1002, the festival of St. Brice, multitudes of every age and sex were butchered. Next year Sweyn reappeared on the south coast, and from this time left the kingdom no rest. He devastated all the country from Exeter to the heart of Wiltshire, burning cities and villages. He consented to a peace in 1007 on payment of 36,000 pounds. Soon the war began again, and was again momentarily ended in 1012 by the payment of 48,000 pounds. In 1013 Sweyn openly declared his purpose of conquering England, and having landed at Gainsborough marched triumphantly from Northumbria to the walls of London. Repulsed from the capital, he marched to Bath, where he was proclaimed king of England, and recognized by the thanes of Wessex, Mercia, and Northumbria. This general defection alarmed Ethelred, and he fled in haste to Normandy and found an asylum with his brother-in-law the Norman king. The death of Sweyn, 2 or 3 weeks later, recalled the fugitive monarch, who inflicted cruelties upon the Danish population which were revenged by Canute the Danish successor. The young prince Edmund, afterward called "Ironside," defended the throne during the last years of Ethelred.

ETHELWULF, 2d king of the Anglo-Saxons, son and successor of Egbert, ascended the throne in 836, died in 857 or 858. Without the vigor of his father, and fitted rather to wear the cowl than wield the sceptre, he began his reign by transferring the provinces of Kent, Essex, and Sussex to the government of his eldest son Athelstan. For many years he was occupied only with incessant contests with the Northmen who annually made inroads into Eng-

land, and though repulsed and defeated, always carried off booty. In 850-'51, a part of them dared for the first time to pass the winter in England. Strongly reënforced in the spring, they sailed up the Thames, sacked Canterbury and London, and met Ethelwulf at the head of the West Saxons at Okely. After an obstinate battle the Danes were defeated with a loss greater, it is said, than they had ever before suffered, and other divisions of their forces were defeated by Ceorle in Devonshire, and by Athelstan at sea. Yet they maintained their settlement on the isle of Thanet, but were cautious in their ravages during the remainder of Ethelwulf's reign. In 855 the king made a visit to Rome, accompanied by his son Alfred, who there received from the pontiff the regal unction and the sacrament of confirmation. He returned through France, where he tarried to marry Judith, the daughter of the French king. His son Athelstan meantime had died, and Ethelbald was usurping the kingdom, when he returned and yielded to the latter the government of Wessex. He survived this partition of his dominions but 2 years, which he passed in acts of charity and devotion.

ETHER (Gr. *αιθηρ*, the upper air), in chemistry, the name given to a class of highly volatile, inflammable, spirituous liquids, possessing a sweetish taste and peculiar fragrance, obtained commonly by distilling alcohol in mixture with some acid. Their composition is somewhat variable according to the acid employed in their preparation, and this gives them their distinctive names, as sulphuric ether, nitric ether, &c. Yet these acids do not in all cases furnish any of the ingredients of the ether, and the same ether may sometimes be produced by the action of other substances upon alcohol, as well as of the acid usually employed. This is especially the case with sulphuric ether, and as it contains no sulphuric acid, and is by far the most common form of ether, it is now admitted into the U. S. and London pharmacopœias by the name of æther, as it was before known in common use. This ether, it is supposed, was known to Raymond Lully, who lived in the 13th century. Valerius Cordus in 1540 described the method of making it. Dr. Frobenius in 1730 first brought it prominently forward in a paper published in the "Philosophical Transactions;" and by a note appended to this, it appears that Boyle and Newton had both directed their attention to it.—The preparation of ether was formerly conducted by distilling in a glass retort a mixture of equal parts of sulphuric acid and alcohol at a moderate heat, and when about one-third of the whole had come over, adding half as much alcohol as before, and again distilling. But a better method is to conduct the process upon a larger scale with the use of a leaden still heated by high steam passed through in a spiral pipe; and the alcohol is best introduced in small quantities at a time by a pipe which passes through the upper part of the still. Such

is the apparatus used at the apothecaries' hall, London. The heating by steam obviates the danger of explosion, to which the process is liable when the vapors that escape come in contact with the flame of a fire or of a lamp. The apparatus given by Brande is a convenient one either on a large or small scale. In a glass flask are introduced 8 parts by weight of concentrated sulphuric acid and 5 parts of spirit of wine of specific gravity 0.834. This is set in a small sand bath, which may be conveniently heated by a gas light. A thermometer graduated at least to 320° F. passes through the cork, the bulb being in the liquid. There is also a tube reaching to the bottom, and expanding at top into a funnel. This is intended to receive more alcohol slowly dropped into it as the process goes on. A glass tube of large bore conveys the vapor through the condenser, which is surrounded with cold water, and the liquid drops from the end of the tube into a proper receiver. By keeping the temperature as nearly as possible to 300°, the ebullition goes on rapidly, and the quantity of liquid in the flask may be kept nearly the same for several hours, the alcohol as fast as it is admitted being converted into the vapor of ether and of water. These condense together, but in the receiving vessel they separate, the water sinking to the bottom together with $\frac{1}{15}$ of its volume of ether dissolved in it. If a weak acid be used or too much alcohol, so that the boiling point of the mixture is reduced below 260°, the alcohol is apt to pass over unchanged. It is important to keep up a rapid, or even violent boiling, at a temperature between 260° and 310°. At about 320° olefiant gas and other undesirable products are generated. By the continuous process of Dr. Brande, a small quantity of sulphuric acid may be made to convert into ether a large quantity of alcohol. It might serve for an indefinite time but for its slow volatilization and the passing over of its vapor with the others. Ether is purified by shaking it in a close vessel with twice its bulk of water. After standing, the ether is poured off, and the water that may be still present is taken up by mixing quick lime with it. Then by distilling, pure ether is obtained.—Ether is remarkable for its great volatility. Its vapor escapes in pouring the fluid from one vessel into another, so that if a lighted candle is near there is danger of the whole being suddenly inflamed. A mixture of 10 volumes of oxygen and one of ether vapor explodes violently by an electric spark. The vapor is so much more dense than air, being as 2.58 to 1, that it can be poured out of one vessel into another, displacing the air in this, and showing its presence by taking fire on the application of a match. Its rapid evaporation produces intense cold; a few drops being made to cover a drop of water and then blown upon through a tube, the water is frozen directly. Ether itself, however, does not freeze, even at 166° below zero. Its boiling point varies with the nature of the vessel containing it; at the

ordinary pressure it boils at 96.5°. Its specific gravity at 68° is 0.718. It has neither an acid nor alkaline reaction; but after being exposed to the air and light, a little acetic acid is formed in it. Ether unites with alcohol in all proportions. It takes up $\frac{1}{15}$ of its volume of water, and water does the same of ether. If water dissolve more than this, the ether may be suspected of being adulterated with water and alcohol. The ultimate constituents of sulphuric ether are carbon 4 equivalents, Hydrogen 5, and oxygen 1, or C_4H_5O , differing from those of alcohol (C_4H_9O) by $H O$, or one atom less of water. The radical ethyle consists of C_2H_5 , and ether is regarded as its oxide, alcohol as its hydrated oxide. Ether is much employed in medical practice as a narcotic, antispasmodic, and stimulant; a teaspoonful of it in a glass of white wine is recommended by Dr. Brande as a remedy in sea-sickness. It is a specific in nervous headaches, and in burns and scalds is applied as a refrigerant. Its most important use, however, has been to produce insensibility to pain by its inhalation when diluted with air. (See ANÆSTHETIC AGENTS.) Several of the ethers exist in a natural state in the fruits, giving to them their peculiar flavors; and the alcoholic liquors distilled from these fruits retain these principles in combination with some acid. Thus enanthic ether combined with enanthic acid forms the oil which contains the fragrance of brandy and some other spirits. Whiskey is thought by Dr. Frankland to owe its flavor to the oily liquid called pelargonic ether; and according to Gregory, this is now manufactured by a secret process, and sold at a high price to impart to new whiskey the flavor of old.

ETHEREGE, or ETHERIDGE, SIR GEORGE, an English comic author, born in 1686, died about 1694. He studied at the university of Cambridge, travelled upon the continent, abandoned the study of law for the culture of letters, and became known as one of the wits and libertines of the reign of Charles II. His comedies entitled the "Comical Revenge, or Love in a Tub," "She Would if She Could," and the "Man of Mode, or Sir Fopling Flutter," are marked by a sprightlier and wittier dialogue than had before been displayed in the English comic drama. The author was an associate of Buckingham, Rochester, and other gay courtiers and pleasure seekers of the time, and he introduced upon the stage the manners and characters with which he was familiar. He also wrote a few comic songs and lampoons. He lived licentiously, wasted his fortune, and died by falling down stairs after a debauch.

ETHICS. See MORAL PHILOSOPHY.

ETHIOPIA (Gr. *αἶθερ*, to burn, and *οὔρα*, countenance), in ancient geography, the name originally given by the Greeks to the southern parts of the known world. It is divided in the poems of Homer into eastern and western Ethiopia, and this distinction is repeated by Herodotus, and by the later Greek and Roman geographers. Eastern Ethiopia appears to have

included southern India, whose inhabitants were called Ethiopians from their color. There were also other Asiatic Ethiopians, an equestrian race, of a darker color than their neighbors, who wore crests made of the hides and manes of horses, and are supposed to have been a Mongolian tribe which had wandered into the steppes of Koordistan. The name Ethiopia was more usually and definitely applied to the country south of Libya and Egypt, between the Red sea on the east and the desert of Sahara on the west, and embracing the modern regions of Nubia, Sennaar, Kordofan, and Abyssinia. In a still narrower sense, the designation was restricted to the province or kingdom of Meroë, which was also called the civilized Ethiopia. African Ethiopia, which is called in the Bible the land of Cush, embraced, according to Pliny, 45 distinct kingdoms; yet as neither the Greeks nor Romans ever penetrated beyond Napata, in lat. 19° N., we are indebted for most accounts of it to Greek imagination. Meroë, between the Nile and the Astaboras, formed the most powerful state, and had a theocratic constitution. The other principal divisions were the Blemmyes, whose aspect was hideous; the Troglodytæ, who lived in caverns; the Macrobiai, or long-lived men; the Ichthyophagi, or fish eaters; and the Creophagi, Chelonophagi, Elephantophagi, Struthophagi, and Ophiophagi, respectively the eaters of flesh, tortoises, elephants, ostriches, and serpents. Fable placed also in this region the race of pygmies. Some parts of Ethiopia were named from their productions, as the land of cinnamon, and of myrrh, and the Jews and Phœnicians went thither to obtain aromatics and ivory. The Ethiopian kings seem to have been chosen from among the priests, and the order of succession gave the crown to the nephew of the king, the son of his sister; and in default of an heir, an election was made. The people practised circumcision, and embalmed their dead in a manner similar to that of the Egyptians. They were of an intrepid, impetuous, and violent character, and yet are represented as loving and practising justice. Homer makes Jupiter visit them, and sit at their feasts. There were many Ethiopian queens named Candace, one of whom became subject to the emperor Augustus. Under the Romans the population of Ethiopia became almost wholly Arabian, and so continued after the introduction of Christianity in the 4th century. When the followers of Mohammed overran the entire region some centuries later, the Arabic element gained complete predominance in it. During the middle ages the Christians and clergy of Abyssinia were designated as the Ethiopian church.

ETHIOPIAN LANGUAGE AND LITERATURE. Of the different dialects spoken in modern Abyssinia, the Amharic and the Tigré are the most remarkable. The former of these shows little affinity with the ancient language of the country, the Geez, or the Ethiopic properly so called, which since the beginning of the

14th century, when a dynastic change made the Amharic the language of the court, has ceased to be the vernacular, and is used only by people of education and learning, in religious and civil documents. This ancient language, which has its name from the inhabitants calling it *lesana geez*, that is, language of science, as it is also called language of books, is of Semitic origin, resembling in roots, structure, and grammatical forms, the ancient South Arabian dialect of the Himyarites, which since Mohammed has disappeared from the peninsula. This favors the hypothesis of some historians, who suppose the Ethiopians to have been a colony from Arabia. The alphabet also of the Geez greatly resembles that of the Himyarites, as found in their remaining inscriptions. It consists of 26 consonants and 7 vowels, which are small marks inseparably connected with the former, thus forming a peculiar syllabic mode of writing, analogous to the Devanagari and some other Indian alphabets. Few of these letters show a resemblance to the Phœnician alphabet, while 24 of them may be traced in the Arabic. There are no diacritical marks; the single words are separated by 2 dots; the accent is difficult; the mode of writing is from left to right, the reverse having been the practice before the introduction of Christianity into Abyssinia. In roots, and forms of expression and construction, the Geez is poorer than the Arabic. According to Gesenius, one-third of all the roots can be traced distinctly in the Arabic, and many other words may be presumed to be of the same origin, while the roots of others can be found in the Hebrew, Syriac, or Chaldaic, some being native African, a few of Greek, scarcely any of Coptic derivation. The Geez has 10 conjugations, 8 of which answer to those of the Arabic, the 5th and the 6th being peculiar. A double infinitive is used substantively, this mood having both an absolute and constructive form. There is no participle. The dual is unknown both in verbs and nouns; the difference of masculine and feminine is observed throughout in the 2d and 3d persons. The relation of the genitive is expressed by an inflection, causing some changes in the terminations, or through the relative pronoun; the dative by prepositions; the comparative and superlative degrees by particles. The plural is formed by affixed syllables, *ân* in masculine, *ât* in feminine nouns, on the principle common to the Hebrew, Arabic, and Aramaic, or by changes in the radical letters, after the manner of the so-called broken plural in Arabic. In the formation of nouns the Geez most resembles the Hebrew, but it has superfluous final vowels, modified in certain cases, in which it is analogous to the Arabic in its nunnation. Beside a few fragments in inscriptions, there are no remnants of the ancient Ethiopian literature of a period preceding the introduction of Christianity under Constantine the Great, but of works composed since that time about 200 are known to European scholars. The Old Testament, translated from the Septuagint by

unknown Christian writers in the 4th century, is extant in manuscripts in Europe, but only a part of it has been printed. The Psalms were published in Ethiopic and Latin by Ludolf (Frankfort on the Main, 1701), and in Ethiopic alone (London, 1815). The version of the New Testament appeared at Rome in 1548, and in the London polyglot Bible. Of versions of apocryphal books, in which the Ethiopic is particularly rich, several have been published, as the "Book of Enoch," translated by Richard Laurence into English (2d edition, London, 1833), and by Hoffmann into German (Jena, 1838), in *Vatis*, translated by Laurence into Latin, and published in both languages (Oxford, 1819). Geez in 1840 (London), and *Ascensio Isaie*. The "Didascalia, or Apostolical Constitution of the Abyssinian Church," was published in Ethiopic and English by Platt (London, 1834). The *Synaxar* contains lives of Abyssinian saints, martyrologies, and the hymns of the Ethiopian church, in rude rhythmical form, every 3 or 5 lines often ending in the same consonant, which forms a kind of rhyme. The profane literature of the Ethiopian language is comparatively poor, consisting chiefly of chronicles, which appear to be of considerable interest, but have not yet been generally accessible. Of these the most remarkable are the *Keber za Nageste*, containing the traditional and legendary history of the once mighty kingdom of Axoom, a copy of which was brought to Europe by Bruce, and a translation of it appended to his travels; and the *Turek Nagushti*, or chronicle of kings. In Europe the Ethiopian language was almost unknown until the time of Job Ludolf, who, being assisted by an excellent native scholar, Abbas Gregorius, made himself master of it, and published an admirable dictionary and grammar (2d improved and enlarged edition, Frankfort, 1702). After a long interval the interest in this language and literature has been revived by the works of Platt, Laurence, Gesenius, Hupfeld, Hoffmann, Rödiger, Ewald, and others, as well as by the contributions of Isenberg, Blumberg, and D'Abbadie.

ETHNOLOGY (Gr. *ἔθνος*, nation, and *λόγος*, doctrine), the science which treats of the relations of the different races or divisions of man to each other, as distinguished from anthropology, which considers the relations of man to other members of the animal kingdom. These two distinct sciences make up the natural history of man. Ethnology has been made synonymous with the natural and the physical history of man, both of which strictly embrace more or less of anthropology. While the latter would require only a single pair of human beings for its study, ethnology presupposes variety of races, and the greater the variety the further do its boundaries extend. Some authors confine the term to the speculative portion of the subject, calling the descriptive part of the science ethnography. In a science so new as this, absolute precision in terms cannot be expected. As anthropology has been treated under its own

title, this article will be limited to ethnology proper. History traces the moral influences of races upon each other, but ethnology treats of the effects of physical agencies upon man, going back long anterior to written records, and, unlike history, argues from effects to causes, from the known to the unknown. Prichard defines it as the archæology of the human inhabitants of the globe. The ethnologist should not only be a naturalist, but should be familiar with philology or the science of languages, archæology or the study of human monuments and remains, and physical geography as far as it relates to climatological and kindred influences on the races. It may well be conceived then, from the difficulties inherent in the subject, and from the rarity with which the necessary qualifications exist in observers, that the science of ethnology is at present in a very unsatisfactory though progressive condition. The ancient writers have contributed very little to ethnology. Among the Greeks, Herodotus and Xenophon give a faint idea of the ancient populations; among the Latins, Sallust, Cæsar, and especially Tacitus, have supplied fuller information, yet so unimportant compared to what they might have done, that Latham well remarks, in reference to the Getæ and Thracians: "The commonest slave dealer of Byzantium or Olbiopolis could have told us more than all the learned men ever employed on such subjects." It is only in comparatively modern times, since the discovery of America, the circumnavigation of the globe, and the explorations of Asia, Africa, and the Pacific islands, that ethnology can be said to have begun to accumulate the materials necessary for a natural classification of the human races. The great problems connected with ethnology are the unity and diversity, the geographical origin or origins, the antiquity, and the future destiny of races; subjects so vast in themselves that they can only be incidentally alluded to here. The question of most exciting interest in regard to the human races at the present day is that of unity and diversity, which is not only interesting to the scientific man, but has been made a stumbling block in the way of philanthropy and theology. Ethnologists have divided themselves into two great schools on this point, of one of which Prichard may be considered the ablest advocate, and of the other Agassiz; the recent advances made in zoology, comparative anatomy, history, geography, philology, and in the interpretation of the Scriptures, have furnished materials for the earnest discussion and support of each side of the question.—The classifications of the races of man have been founded principally upon the complexion, nature of the hair, shape of the skull, conformation of the pelvis, and character of the languages, either alone or in combination. Linnæus, in the first edition of his *Systema Naturæ*, makes 4 divisions of the genus *homo*, founded upon the color of the skin, viz.: 1, European, whitish; 2, American, coppery; 3, Asiatic, tawny; and 4, African, black. The divisions proposed by Buf-

fon were 5: the Hyperborean (including the inhabitants of the polar regions and of eastern and central Asia, or Laplanders and Tartars), Southern Asiatic, European, Ethiopian, and American. Blumenbach adopted these, changing the names of some of the divisions, and more accurately defining their geographical distribution. The classification of Blumenbach, fully given in the article ANTHROPOLOGY, divides mankind into the 5 classes of Caucasian, Mongolian, Ethiopian, American, and Malay, and is founded on the combined characters of the complexion, hair, and skull. This classification is followed by Lawrence in his "Lectures on the Natural History of Man;" this writer was among the first to hint at the possible diversity of origin of the races. Before Blumenbach, Camper, a Dutch anatomist, attempted to classify the races by the shape of the skull, and his measurements, constituting the facial angle, are still of considerable value to the ethnologist and anthropologist. He says: "The basis on which the distinction of nations is founded may be displayed by two straight lines, one of which is to be drawn through the meatus auditorius or opening of the ear to the base of the nose, and the other touching the prominent centre of the forehead, and falling thence on the most advancing part of the upper jaw bone, the head being viewed in profile." This gives the facial angle; and the occipital angle may be measured in a similar manner. The objections to this mode of measurement are the varying thickness of the skull, development of the facial cavities, and projection of the front teeth, and its application to only one part of the skull; the method of Cuvier is better, which compares the areas of the cranium and face sawed vertically on the median line from before backward; according to this measurement the area of the former in the highest races is 4 times that of the face, in the negro the area of the face being $\frac{1}{2}$ larger. The *norma verticalis* of Blumenbach measures the breadth of the skull and the projection of the face, and consists in viewing skulls from behind and above, the eye being fixed on the vertex of each; the direction of the maxillary and malar bones, the breadth of the oval contour of the head, the form of the frontal bones, and other characters considered as national, are presented in this view. The comparisons of skulls made by Dr. Morton in his ethnological works are based on the cubic contents of each cranium, measured by noting the quantity which they will hold of any small granular substance. The examination of the base of the skull, as suggested by Owen, so valuable in anthropology, is of little importance in ethnology.—Cuvier divides mankind into 3 stocks: 1, Caucasian, with the branches Armenian, Indian, and Scythian, or Tartar; 2, Mongol or Altaic, with the branches Calmucks, Kalkas, Mantchoos, Japanese, and Siberians; 3, Negro or Ethiopian. He is undecided as to the position of the Malays, Alfooroos, and Papuans, and is inclined to refer the American Indians to the

Mongol stock. He adopts the ill-chosen term "Caucasian" from Blumenbach, which has now become both incorrect and inconvenient; the term originated from the prevalent belief at that time that the white races had their cradle in the mountains of Caucasus, and from the fact that some of the finest known specimens of man (the Circassians and Georgians) inhabit that region; as there is no foundation in truth for such a belief, the name has been given up by many modern writers. Fischer, in his *Synopsis Mammalium*, divides man into *homo Japeticus*, with the branches *Caucasicus*, *Arabicus*, and *Indicus*; *H. Neptunianus*, with the branches *Occidentalis* and *Papuensis* (the Malay race); *H. Scythicus* (Calmucks and Mongols), with the branches *Sinicus* and *Hyperboreus*; *H. Americanus* (South American indigenes), with the branch *Patagonus*; *H. Columbicus*, the indigenes of North America, eastern Mexico, the Antilles, &c.; *H. Æthiopicus*, with the branches *Caffer*, *Melanoides* (Papuans, Feejeeans, &c.), and *Hottentottus*; and *H. Polynesius*, the Alfooroos, Australians, &c. Lesson, in his *Mammalogie*, divides the races, according to complexion, into the white or Caucasian, the yellow or Mongol, and the black or negro stocks. His later arrangement in his *Spécies des mammifères* is the following: 1, the white race; 2, the bistre black or dusky race, including Hindoos, Caffres, Papuans, and Australians; 3, the orange-colored, or Malay race; 4, the yellow race, including the Mongolians, Oceanic and South American branches; 5, the red, the North American and Carib races; 6, the black race, including the African and Asiatic negroes, Nigritians, Tasmanians, Hottentots, and Bushmen. The divisions of Duméril are: the Caucasian or Arab-European, Hyperborean, Mongolian, American, Malay, and Ethiopian. Virey makes 2 species of the genus *homo*: the first with a facial angle of 85° to 90° , including the white Caucasian race, the yellow Mongolian, and the copper-colored American; the second with a facial angle of 75° to 82° , including the dark brown Malay, the black or negro race, and the blackish Hottentots and Papuans. The sections of Desmoulins are: Celto-Scyth-Arabs, Mongols, Ethiopians, Euro-Africans, Austro-Africans, Malays or Oceanians, Papous, negro Oceanians, Australasians, Columbians, and Americans. Bory de St. Vincent amplifies considerably the divisions of Desmoulins, making 15 stocks in 3 classes, as follows: I. Races with smooth straight hair, peculiar to the old world, including: 1, the Japetic stock (named from Japetus, whom the ancients regarded as the progenitor of the race inhabiting the West, *audax Japeti genus*, the original seat of which is the mountain chains nearly parallel to lat. 45° N.), the Caucasian, Pelasgic, Celtic, and Germanic races; 2, the Arabian stock, including the ancient Egyptians, North Africans, and Adamić or Syrian races; 3, the Hindoo stock; 4, the Scythic stock, or Tartars; 5, the Chinese stock; 6, the Hyperborean stock (Lap-

landers, &c.); 7, the Neptunian stock, including the Malays, Oceanic and Papuan races; 8, the Australasian stock. II. Races of the new world with straight hair, including: 9, the Columbian stock, the North American races; 10, the American stock, the South American races; 11, the Patagonian stock. III. Crisp-haired or negro races, including: 12, the Ethiopian stock, or black races of central Africa; 13, the Caffre stock; 14, the Melanian stock, or races of Madagascar, New Guinea, Feejee islands, Van Diemen's Land, &c.; and 15, the Hottentot stock. Prof. Broc, in his *Essai sur les races humaines* (1836), adds many subgenera to the divisions of Bory de St. Vincent. Kant divides man into 4 varieties, white, black, copper, and olive, corresponding respectively to the Caucasian, Negro, American, and Mongolian. Hunter makes 7 varieties; Metzan 2, white and black. Luke Burke, late editor of the "London Ethnological Journal," makes 63 races of man, 28 being varieties of the intellectual and 35 of the physical races. Retzius divides all heads into short or brachycephalic, and long or dolichocephalic, each of which he again subdivides into those with straight and with prominent jaws. Prof. Zeune adopts 3 types of skull for the eastern and 3 for the western hemisphere, as follows: I. High skulls, including: 1, the Caucasian race in the old world, and 2, the Appalachian in the new. II. Broad skulls, including: 3, the Mongolian, and 4, the Carib races. III. Long skulls, including: 5, the Ethiopian, and 6, the Peruvian races. This is an exceedingly unnatural arrangement.—Dr. Prichard, in his "Researches into the Physical History of Mankind" (1826–1847), refers mankind to 7 stocks or classes of nations, the principal mark of distinction among which is the peculiar form of the skull; these are: 1, the Iranian (the Caucasian of previous writers), in the form of the skull and in their physical traits resembling Europeans, including some Asiatic and African nations; 2, the Turanian or Mongolian; 3, the American, including the Esquimaux and kindred nations; 4, the Hottentot and Bushman; 5, the Negro; 6, the Papuan or woolly-haired Polynesians; and 7, the Australian and Alfooroo nations. Taking the color of the hair as a principal character, Prichard makes 3 great varieties: 1, the melanic, with very dark or black hair; 2, the xanthous, with yellow, red, or light brown hair, blue or light eyes, and fair skin; and 3, the leucous, or albinos, with white or pale yellow hair, very soft, fair, and delicate skin, and a red hue to the choroid of the eye. According to this author, examples of these varieties are found in all the races. Martin, in his "Natural History of Man and Monkeys" (1841), divides the human race into the following 5 stocks: 1, the Japetic, including the European branch, or the Celtic, Pelasgic, Teutonic, and Slavonic nations; the Asiatic branch, or the Tartaric, Caucasian, Semitic, and Sanscritic nations; and the African branch, or the Mizraimic nations (ancient Egyptians, Ethi-

opians, Abyssinians, Berbers, and Guanches); 2, the Neptunian, including the Malays and Polynesians; 3, the Mongol, including also the Hyperborean; 4, the prognathous (a term adopted from Prichard), including the Negro, Hottentot, Papuan, and Alfooroo branches; 5, the occidental, including the indigenes of North and South America. Dr. Prichard, in his "Natural History of Man" (3d edition, 1848), after defining species and varieties, devotes many pages to show the influence of external conditions in modifying the races of animals and man; unable to find specific characters in the differences of color, structure of the hair, shape of the skull, or proportions of any parts of the skeleton, he points out 3 principal varieties of conformation of the head, which characterize respectively the savage or hunting, the nomadic or wandering, and the civilized races of mankind. Among African and Australian savages, the jaws are prolonged forward, constituting the prognathous form of head; among the wandering Mongolians, the skull is pyramidal, and the face broad and lozenge-shaped; and in the civilized races the skull is oval or elliptical. There are numerous nations which present forms of transition between these principal ones, according to their approach to civilization on the one hand, or their relapse toward barbarism on the other. He makes a similar division of man into 3 races according to the relations of their languages, which of all traits "seem to be the most permanently retained, and can be shown in many cases to have survived even very considerable changes in physical and moral characters." Cuvier referred the original seats of the human race to mountain chains, the Caucasian to Mt. Caucasus, the Mongolian to Mt. Altai, and the Negro to the chain of the Atlas mountains. The Hebrew Scriptures make the traditional birthplace of mankind the banks of 4 rivers, 2 of which have been recognized as the Tigris and Euphrates, in a land rich in animal and vegetable productions. Prichard admits 3 great centres of earliest human civilization, comprising most of the tribes known to antiquity; in his own words: "In one of them, the Semitic or Syro-Arabian nations exchanged the simple habits of wandering shepherds for the splendor and luxury of Nineveh and Babylon. In a second, the Indo-European or Japetic people brought to perfection the most elaborate of human dialects, destined to become, in after times and under different modifications, the mother tongue of the nations of Europe. In a third, the land of Ham, watered by the Nile, were invented hieroglyphical literature and the arts, in which Egypt far surpassed all the rest of the world in the earlier ages of history." These 3 divisions do not correspond to the 3 indicated by the form of the skull, all of the former being more or less civilized, and having the oval or elliptical head. The Syro-Arabian or Semitic race includes the Syrians, Jews, and Arabs; Baron Larrey says that the Arabian race furnishes the most perfect type of the he-

man head, and believes that the cradle of the human family is to be found in Arabia; this race is intellectual, energetic, and restless. The Egyptian or Hamitic race he regards as indolent, superstitious, and stationary in its own land, which is little else than a vast sepulchre; it is entirely unlike the negro races of Africa. The Indo-European, Japetic, or Aryan race comprises the Hindoos, Persians, Afghans, Koords, Armenians, and the nations of Europe with their American colonies; he believes that the Aryan nations, on their arrival in Europe, found the country occupied by Allophylian people, who were also of eastern origin, but had migrated westward at an earlier age. The 5 great nomadic races inhabit the large central region of Asia, and belong to the Mongolian division of authors; they are characterized by pyramidal heads and broad faces. These races are: the Ugrian in the north-west, from whom the Magyars are believed to have descended, and of which the Finns, Lapps, Ostiaks of the Obi, and other Siberian tribes, are varieties; the Turkish, with their nomadic tribes, and the Ottoman branch; the Mongolian, including the Calmucks; the Tungusian, in the mountainous region between Lake Baikal and the Okhotsk sea; and the Bhotiya, inhabiting Thibet and the Himalaya chain. To the races with pyramidal skulls belong the fish-eating tribes bordering on the Arctic ocean, including the Namollos of north-eastern Asia and the Aleutian islands (akin to the Esquimaux), Koriaks, Kamtchatkans, Samoiedes, and Koorilians. To the Mongolian division belong also the Chinese, Japanese, Coreans, the Indo-Chinese beyond the Ganges, and the aborigines of India distinct from the Hindoos (the latter belonging to the Arabian stock). Among the Allophylian races before alluded to as existing in regions afterward conquered by the Syro Arabian nations, may be mentioned the Caucasians, to this day successfully resisting the Russian power, the Iberians of the Pyrénées, the Berbers of the Atlas chain, and the Guanches of the Canary islands. Among African races, the Abyssinian, a fine dark, but not negro people, is interesting as having preserved, "in the midst of Moslem and pagan nations, its peculiar literature, and its ancient Christian church," and having remains of a wide-spread Judaism, and a language approaching to the Hebrew. Of the black races of the interior of Africa the principal are the Senegambian, including the Mandingos and the Foola. The true negro characters are most strongly marked on that portion of the coast "which encircles the projecting region of western Africa to the inmost angle of the bight of Benin," the centre of the slave trade. The Hottentots and Bushmen of South Africa in many respects resemble the nomadic Mongolians of Asia; the warlike Caffres are said to combine the prominent forehead and nose of the European, the thick lips of the negro, and the high cheek bones of the Hottentot. (Fuller details on the kindred races have been

given in the recent works by Drs. Barth and Livingstone.) The oceanic races Prichard divides into Malayo-Polynesian, Pelagian Negroes, and the Alfoorians of the New Guinea group of islands (which include the Australians). The American races are distinguished from those of the old world by their moral and social traits, and by the structure of their languages. The Mexican tribes, which, according to Prichard, arrived on the central plain of Anahuac from the north in the 7th century, found this region inhabited by the nations which have left the splendid ruins of Palenque, among whom were the Othomi, remarkable for their monosyllabic idiom; the Esquimaux and the Athabascas, with a Mongolian cast of countenance, extend across the northern portion of the continent from ocean to ocean; south of these, east of the Mississippi, were the Algonquin-Lenape and the Iroquois, with their numerous tribes, almost always at war with each other, and the Alleghanian nations toward the south; west of the Mississippi, the Sioux and the Pawnees; on the Pacific coast, the dark Californians and the tribes of the N. W. coast; in South America, the Andean nations, the Brazilio-Guarani, and the Mediterranean or central groups.—Dr. Latham, in his "Natural History of the Varieties of Man" (1850), separates the human family into 3 primary divisions, the *Mongolidæ*, *Atlantidæ*, and *Japetidæ*. The *Mongolidæ* inhabit Asia, Polynesia, and America; their languages are aptotic (without cases) and agglutinate, and their influence on the history of the world has been material rather than moral. He divides them into: *a*, Altaic *Mongolidæ*, including the Seriform (Chinese, &c.) and Turanian (Mongol) stocks, from the latter of which are descended the Magyars; *b*, Dioscurian *Mongolidæ* (the Caucasian races of earlier writers); *c*, oceanic *Mongolidæ*, including Malays, Polynesians, Papuans, and Australians; *d*, hyperborean *Mongolidæ*, Samoiedes and similar nations; *e*, peninsular *Mongolidæ*, Coreans, Japanese, and the nations of the islands and peninsulas of north-eastern Asia; *f*, American *Mongolidæ*, the Esquimaux and American Indians; *g*, Indian *Mongolidæ*, the inhabitants of Hindostan, Cashmere, Ceylon, &c. The *Atlantidæ* inhabit Africa; their languages are agglutinate, rarely with an amalgamate inflection, and, with the exception of the Semitic section, their influence on the world's history has been inconsiderable. He divides them into: *a*, negro *Atlantidæ*, occupying the central negro area of the continent; *b*, the Caffre *Atlantidæ*; *c*, the Hottentot *Atlantidæ*; *d*, the Nilotic *Atlantidæ*; *e*, the Amazirgh *Atlantidæ*, or Berbers; *f*, the Egyptian *Atlantidæ*; *g*, the Semitic *Atlantidæ*, or Copts, Abyssinians, Arabians, Syrians, Hebrews, &c. The *Japetidæ* inhabit Europe; their languages are rarely agglutinate and never aptotic, and their influence on the moral history of man has been greater than that of either of the others. He divides them into: *a*, occidental *Japetidæ*, the Celts and their branches; *b*, the

Indo-Germanic Japetids, the European and Iranian Indo-Germans. In the article "Ethnology" in the "Encyclopædia Britannica," Dr. Latham gives a more recent classification, as follows: *a*, Asiatics and northern Europeans, Polynesians, and Americans, with the classes Mongolians, Iranians, Indians, Oceanians, and Americans; *b*, central and southern Europeans; *c*, Africans and south-western Asiatics, with the classes Semitic, Nilotic, Caffre, Negro, and Hottentot. In both these classifications the divisions are made on philological grounds; he seems satisfied with the doctrine: "1, that as a matter of fact, the languages of the earth's surface are referable to one common origin; 2, that as a matter of logic, this common origin of language is *prima facie* evidence of a common origin for those who speak it."—Dr. Pickering, in the "Races of Man, and their Geographical Distribution" (1848), enumerates 11 races, divided into 4 groups, according to complexion, as follows: *a*. White, including: 1, Arabian, with nose prominent, lips thin, beard abundant, and hair straight and flowing; 2, Abyssinian, with complexion hardly becoming florid, nose prominent, and hair crisped. *b*. Brown, including: 3, Mongolian, beardless, with perfectly straight and very long hair; 4, Hottentot, with negro features, close woolly hair, and diminutive stature; 5, Malay, with features not prominent in profile, darker complexion, and straight and flowing hair. *c*. Blackish brown, including: 6, Papuan, with features as in 5, abundant beard, harsh skin, and crisped or frizzled hair; 7, Negrillo, apparently beardless, with diminutive stature, negro features, and woolly hair; 8, Indian or Telingan, with Arabian features, and straight and flowing hair; 9, Ethiopian, with features intermediate between the last and the negro, and crisped hair. *d*. Black, including: 10, Australian, with negro features, but straight or flowing hair; and 11, Negro, with close woolly hair, flattened nose, and very thick lips. Six of the races are Asiatic, and 4 African, while the white race is common to both hemispheres; the Malay, Negrillo, and Papuan are island races, the other 8 are continental; the Malay is a truly maritime race, and the most widely scattered of all. Assuming the population of the globe to be 900,000,000, he gives to the races the following numbers according to the above figures: 1 has 350,000,000; 3, 300,000,000; 5, 120,000,000; 8, 60,000,000; 11, 55,000,000; 9, 5,000,000; 2, 6, and 7, each 3,000,000; and 4 and 10, each 500,000. He considers table-lands as the natural birthplaces of civilization, and finds 4 such, in Mexico, Peru, Thibet, and Abyssinia; he regards man as "essentially a production of the tropics, since he is born without natural clothing;" he thinks there is no middle ground between the admission of 11 distinct species in the human family and the reduction to one, and that, if the latter opinion be adopted, it implies a central origin, and that origin probably the African continent. Prof. Dieterici, an eminent Prussian statistician,

gives the following estimate of the population of the earth in "Petermann's Journal" for Jan. 1859. According to him, the total population of the globe is about 1,300,000,000, divided as follows: in Europe, 272,000,000; in Asia, 755,000,000; in Africa, 200,000,000; in America, 59,000,000; in Australia, 2,000,000. Divided by races, there are 375,000,000 Caucasians (the greater part in Europe), 528,000,000 Mongolians, 200,000,000 Malays, 196,000,000 Africans, and 1,000,000 Americans. In this estimate, the Africans, Malays, and Mongolians are probably overrated, and the Americans certainly greatly underrated. Divided by religions, about 25 per cent. are Christians, 1 per cent. Jews, 46 per cent. Asiatic religions, 12½ per cent. Mohammedans, and 15½ per cent. heathens; the Christians include about ¼ Roman Catholics, a little more than ¼ Protestants, and a little less than ¼ Greeks.—Dr. S. G. Morton, whose principal works are the *Crania Americana* (1839), and the *Crania Egyptiaca* (1844), divides man into the following groups in his catalogue of skulls, more for convenience of study and examination than as an attempt at scientific classification: I. Caucasian group, with the Scandinavian, Finnish or Tchudic, Suevic, Anglo-Saxon, Anglo-American, Celtic, Slavonic, Pelasgic, Semitic, Berber, Nilotic, Indostanic, and Indo-Chinese races; II. Mongolian group, with the Chinese and Hyperborean races; III. Malay group, with the Malayan and Polynesian races; IV. American group, with the barbarous and Toltecan races; V. Negro group, with the native Africans, Hovas, and Alfoorian races; VI. the mixed races, Copts, Nubians, &c.—Van Amringe ("Outline of a new Natural History of Man," 1848) believes that there are 5 species of mankind: 1, the Semitic, including the Caucasian nations generally, of strenuous temperament; 2, the Japetic, including the Mongolian races, Esquimaux, Aztecs, and Peruvians, of passive temperament; 3, the Ishmaelitic, including most of the Tartar and Arabian tribes and the American nations, of callous temperament; 4, the Canaanitic, including Negroes and Australians, of sluggish temperament; 5, the Esanitic, including Malays and long-haired Negroes; this last he regards as doubtful.—Weber reduces the forms of the human pelvis to 4, which correspond to the forms of skull characteristic of the several races; these are the oval, most frequent in Europeans; the round, most frequent in the American nations; the square, most common in people resembling Mongolians; and the oblong or wedge-shaped, most common in the nations of Africa.—Hamilton Smith, in his "Natural History of the Human Species" (Boston ed. 1851), regards Thibet, the Gobi desert, and the surrounding mountain chains, either as the primitive cradle of man, or as the locality where a portion of human beings found safety after some great convulsion or change of the earth's surface; he illustrates his views by a diagram in which the apex of an equilateral triangle

points to the north, the southern line representing the Himalaya chain with its streams ending at the Indian ocean, the eastern similarly leading to the Pacific, and the western to a sea gradually contracted into the Caspian. On the south of this triangle he places the woolly-haired or tropical type, on the west the bearded or Caucasian type, and on the east the beardless or Mongolic type.—Prof. Agassiz, in the “Types of Mankind,” by Messrs. Nott and Gliddon (1854), gives a sketch of the natural provinces of the animal world (see FAUNA), and their relation to the different types of man, in which he concludes “that what are called human races, down to their specialization as nations, are distinct primordial forms of the type of man.” He makes the following realms: I. Arctic, inhabited by Hyperboræans; II. Asiatic, by Mongols; III. European, by white men; IV. American, by American Indians; V. African, by Nubians, Abyssinians, Foola, Negroes, Hottentots, and Bosjesmans; VI. East Indian or Malayan, by Telingans, Malays, and Negrillos; VII. Australian, by Papuans and Australians; and VIII. Polynesian, by South sea islanders. Dr. Nott, in the same work, after stating that in the present state of our knowledge all classifications must necessarily be arbitrary, says that the 5 usually admitted great divisions of man comprehend many original subdivisions; the nearest approach to a scientific classification he considers that of Agassiz, founded on the relation of man to zoological provinces. In a subsequent work (“Indigenous Races of the Earth,” 1857) Messrs. Nott and Gliddon give an ethnographic tableau in which the races are divided zoologically according to the 8 realms of Prof. Agassiz; they are also grouped physiologically (after Desmoulins, Achille Comte, and O. D’Halloy) into 65 families, 7 belonging to realm 1 of Agassiz, 12 to realm 2, 16 to realm 3, 14 to realm 4, 8 to realm 5, 8 to realm 6, 2 to realm 7, and 8 to realm 8—taking the numbers as given above, which are somewhat changed in the last work. The same realms have also their corresponding classes arranged linguistically, after Maury, Crawford, Logan, &c., as follows: realm 1, with the Finno-Ougrian, containing 6 groups; realm 2, with the Tartarian, Sinic, North and South Dravidian, containing 5, 6, 4, and 6 groups respectively; realm 3, with the Ougrian, Iberian, Indo-Germanic or Japetic, Semitic, and Hamitic, containing respectively 3, 1, 6, 9, and 4 groups; realm 4, with the northern, central, and southern, containing 6, 4, and 4 groups; realm 5, with the Atlantic, Mandingo, upper Guinean, upper Soodanian, delta of the Niger, basin of the Tchad, central Africa, Senegambian, Guinean, Congo, Madagascar, and Hottentot, containing 4, 9, 3, 4, 3, 1, 2, 4, 3, 8, 1, and 3 groups; realm 6, with the polyglot class, containing 13 groups; realm 7, with the polyglot class, containing 2 groups; and realm 8, with the monoglot and polyglot classes, containing 4 and a single group.—The above classifications, the most important and generally accepted in

variously modified forms, though none of them natural or satisfactory, will suffice to show the imperfection of the science of ethnology. The limits of this article will permit only an allusion to the great questions which are intimately connected with this subject, such as the theories of unity or diversity of origin of the races; the effects of physical agents in producing varieties in animals and man; the phenomena of hybridity; the geographical distribution, migrations, and affiliations of the species; disputed points in archæology, philology, chronology, and physical geography; and the bearings of these various researches upon the theological opinions of the day. If ethnology is to advance beyond the above given views of Prichard, it is probably by the study of philology, zoology, and archæology, as initiated by Bunsen, Lepsius, Morton, Agassiz, Nott, and Gliddon, that further light and progress will be obtained. Those who wish to pursue this interesting and difficult subject are referred to the various authors mentioned in this article, and especially to the copious references of the works of Nott and Gliddon, and to the Boston edition of Hamilton Smith. A detailed account of the different Asiatic, European, and African races is given by Dr. Latham in his last work, “Descriptive Ethnology” (2 vols. 8vo., London, 1859).—As to the time that man has existed on the earth, there is great difference of opinion from the limited Hebrew chronology of about 6,000 years to the nearly 22,000 years adopted by Bunsen; according to the latter, the flood took place in northern Asia between 10,000 and 11,000 years B. C., at which time the Aryans emigrated from the valley of the Oxus and Jaxartes, and the Shemites from the valley of the Tigris and Euphrates. In his address before the British association at Leeds, in Sept. 1858, Prof. Owen alludes to Mr. Horner’s examination of the rate of increase of the sediments of the Nile in Egypt as a test of the lapse of time, from which the existence of man 13,875 years ago is inferred; of man, moreover, in a state of comparative civilization. Prof. Max Müller has also attempted to extend the history of the human race by the perception and application of analogies in the formation of modern and ancient languages. The majority of naturalists will perhaps agree with Prof. Owen when he says: “I may advert to the uniform testimony of different witnesses—to the concurrence of distinct species of evidence—as to the much higher antiquity of the human race than has been assigned it in historical and genealogical records.”

ETHYLE (Gr. *αιθηρ*, upper air, and *υλη*, material), the name given by Berzelius to what was then a hypothetical substance, which he regarded as the base of ether, and of which ether is the oxide. It was not isolated during his life; but in 1849 Dr. Frankland obtained it by the action of zinc upon its iodide at a very high temperature. It is a colorless inflammable gas, without odor, of specific gravity 2.00394. Under pressure of $2\frac{1}{2}$ atmospheres, it becomes a color-

less transparent fluid. Composed of C_4H_8 , it is represented by the symbol E.

ETNA (Lat. *Ætna*, probably from Gr. *αἶθω*, to burn), a volcano of Sicily, called by the inhabitants of the island Mongibello, from the Saracen *Gibbel Uttamat*, or mountain of fire. It rises from the E. coast of the island, midway between its N. and S. extremities. The port of Catania is on the prolongation of its S. foot, and, as the history of this once wealthy and highly populous town shows, is by no means beyond the reach of its devastating lava currents. North of the mountain is the Val di Demone, watered by the river Alcantara, and 30 miles S. of it is the N. margin of the Val di Noto, in which the waters of the Giaretta find their way toward the coast amid the ancient scoræ of the great volcano. The country between these rivers is occupied by the mountain with its various ridges, volcanic cones, and deep depressions, which cover altogether an area of about 87 miles in circumference; yet the lava has spread far beyond these limits. In the midst is the apex of the great conical mass, the highest summit, as ascertained trigonometrically by Capt. Smyth in 1815, being 10,874 feet above the sea. Sir J. Herschel in 1824, ignorant of this measurement, determined the height by careful barometrical measurement to be 10,872½ feet. The latitude of the point is $37^{\circ} 43' 31''$ N., and the longitude is 15° E. The cone, at the summit of which is the great crater, is in the midst of a comparatively plane region, 9 miles in circumference, the highest point being 1,100 feet below the principal apex. Around the mountain, at its base, is a fertile and delightful region known as the *regione culta*. Near Catania this is 11 miles broad, till one reaches in ascending the *regione silvosa*, or woody district; but on the N. side the wood skirts the mountain to within half a mile of its foot. This lowest belt is the region of cultivation; towns and villages are clustered upon it; and in the rich soil of the decomposed lava and tufa are flourishing plantations of olives, vines, corn, fruits, and aromatic herbs. Though, in the frequently recurring eruptions of the volcano, some of these are often swept off, or buried beneath the flow of lava, the attractions of the delicious climate, and of a soil so readily producing the necessary sustenance of life, overcome the fears of a people familiar with the dangers, and render them comparatively indifferent to the annoyances of the sharp volcanic dust that, according to Capt. Smyth, injures and disfigures their eyes, their persons, furniture, and houses. The woody region encircles the mountain in a belt 6 or 7 miles in width; but the extensive forests are much broken in upon by the ravages of the lava. Here one passes through fine groves of chestnut and cork trees, and in the higher portions pines of great magnitude abound, together with oak, beech, and poplar, and hawthorn of immense size. A cluster of what appeared to be 7 chestnut trees growing together is described by Capt. Smyth, the largest of which measured 38 feet in

circumference, and the whole 163 feet. The inner portion is much decayed, and a public road passes through the clump of trees. This region affords pasturage for many herds and flocks. Its elevation gives it a cooler and more agreeable temperature than that of the lowest belt. At the height of 5,362 feet is the Goat's cavern or grotto, frequented by these animals in bad weather, and formerly a resting place for travellers, until the shelter known as the English house was built immediately under the cone, at the height of 9,592 feet, at the expense of some British officers who were stationed in Sicily. The upper edge of the woody region is estimated at 6,279 feet above the sea. Beyond it is the cold and desolate zone of the mountain called the *regione deserta*. Its surface spreads out in broad tracts, compared to plains, which are rough and black with the naked lava and scoræ, or white with drifts of snow, which perpetually cover the highest summits. These also collect in the crevices and grottos of this portion of the mountain, and becoming solidified into ice, they furnish most grateful supplies of this material to the inhabitants of the island, and of Malta and the neighboring region of Italy. In 1828, when the whole country was parched with the excessive heat, a quarry of perennial ice was opened under a stratum of lava, so situated that this must have flowed in a melted state at some distant period over the snow, which, as suggested by Sir Charles Lyell, was no doubt protected from the action of the heat by a previous covering of fine dust and scoræ. The bishop of the diocese derives a revenue from the sale of this ice, and what is obtained from a small portion on the N. side of the mountain is said to amount to £1,000 per annum. The great crater is upon a mountain of stones and ashes, which rises about 1,100 feet above its base in this snowy tract. The diameter of its mouth is estimated by different travellers at from 2½ to 4 miles, and the depth from 600 to 800 feet. Sulphurous smoke continuously ascends from it, and rumbling noises are at all times heard. The view from this summit at sunrise is magnificent. The mountain itself, lying directly beneath the eye of the observer, which can penetrate even into the inferior cones that are distributed upon its flanks, presents the most original feature of the landscape. These cones, however, are best seen from the lower borders of the desert region, where, as stated by Sir Charles Lyell, they afford "one of the most delightful and characteristic scenes in Europe. They are seen of every variety of height and size, and are arranged in beautiful and picturesque groups. However uniform they may appear when seen from the sea, or the plains below, nothing can be more diversified than their shape when we look from above into their craters, one side of which is generally broken down." Of these secondary volcanoes Lyell enumerates no less than 80 which are of considerable dimensions, and one of these, called Monte Minardo, near Bronte, is 700 feet high; and the double hill Monti Rossi, near Nicolosi, formed in 1669, is 450 feet high, with a

base 3 miles in circumference. They are produced by lateral eruptions in the desert region or in the wooded belt below. In the latter their height is subsequently reduced by the flow of lava from higher sources, which gathers around, and in some instances buries them and even pours into their craters.—The earliest recorded eruption of Etna is one mentioned by Diodorus Siculus, which caused the Sicani, who then lived near the mountain, to desert its vicinity and move further to the south. No date is given to this event, but it appears to have happened before the Trojan war. The next are 3 eruptions referred to by Thucydides, of which one was in 475 B. C., one in 425, and one supposed to have been in 565. These, added to the later recorded eruptions to the present time, make nearly 60 in all. The most important are those of 1669, 1755, 1787, 1792, and 1852. An earthquake in March, 1669, destroyed all the houses in the village of Nicolosi, situated 10 miles from Catania, near the lower margin of the wooded district. Streams of lava not many days afterward broke forth from chasms which opened in different parts of the mountain. These destroyed as many as 14 villages. From a gulf that formed near Nicolosi, the sand and scorice were projected that produced in the course of 3 or 4 months the double cone Monti Rossi. A fissure 12 miles long was formed, which emitted a most vivid light, and extended to within a mile of the summit of Etna. Afterward 5 other parallel fissures opened, which gave forth smoke and loud bellowing noises. These fissures, which were without doubt partially filled with lava, afford an illustration of the manner in which the porphyritic dikes are formed, which are seen cutting the lavas, and projecting in the form of walls from the precipitous sides of the deep valleys of the mountain; and also of the origin of the trap dikes of older formations. By the flow of the lava among the deep caverns within the mountain, its vaulted foundations were melted away, and the crest, rent with numerous fissures, settled down into the vacant spaces. To protect the city of Catania, its walls next the mountain had been raised to the height of 60 feet; but the lava, irresistible as the swelling tide, and as slow in its motion, rose steadily till it overtopped the rampart, and poured a cascade of liquid fire into the midst of the houses. Long afterward, when excavated by the prince of Biscari, the solid lava was brought to view, its layers curling over the wall, as if just petrified in their flow. Its rate of progress varied greatly with the consistency of the melted matter and the slope of the surface. The greater part of the 15 miles of its flow to the sea was accomplished in 20 days, but the last 2 miles were only at the rate of 22 feet per hour. Its surface exposed to the air was a crust of solid rock; through the side walls streams of the fluid lava often burst out, and by excavating into the great current at suitable places the flow might be diverted in new directions. Attempts that were made to do this by some of the inhabitants of Catania,

in order to protect their town, were opposed with arms by the people of Paterno, as the new current threatened to bring destruction upon their habitations. In some places hills of older lava were melted into the flowing stream, and thus swept away. In others the cooling matter taking an arched form protected the objects upon the surface by enclosing them in grottos of lava. Thus were preserved, and afterward obtained by excavating into the solid lava to the depth of 85 feet, many valued articles from one of the churches of Mompiliere, one of the towns overflowed by this eruption. As Lyell observes, it seems very extraordinary that any works of art, not encased with tufa, like those in Herculaneum, should have escaped fusion in hollow spaces left open in this lava current, which was so hot at Catania, 8 years after it entered the town, that it was impossible to hold the hand in some of the crevices. The great lava current as it flowed into the sea had spread over a width of 600 yards, and its depth was estimated at 40 feet. The water was thrown into violent commotion by this intrusion of heated matter. Sounds louder and more terrific than peals of thunder were constantly sent forth, and the light of the sun was darkened by the clouds of vapor that arose. The fish were destroyed along the coast, and many months passed before the water became again clear and transparent.—The eruption of 1755 is remarkable for a great inundation caused by the flow of two streams of lava upon a vast collection of snow. For 8 miles down the flanks of the mountain the torrent poured, sweeping on the loose scorice and blocks of lava, which were deposited in the plains below. The inhabitants believed that the water was discharged from the crater itself, and the stories of its saltness and of the marine shells contained in it are still found in the popular accounts of this eruption.—The successive piles of lava which compose the great mass of Etna, and the fossiliferous strata which crop out on the more exposed eastern side of the mountain, afford some interesting data bearing upon the time that has elapsed during the accumulation of these materials. For, as observed by Ovid in presenting the views of Pythagoras, there was a time when Etna was not a burning mountain, and a time will arrive when it will cease to be such. This subject has been admirably treated by Sir Charles Lyell in his "Principles of Geology," and illustrated from the drawings he prepared in his examinations of the localities. The lavas, as seen on the southern and eastern sides of the mountain, rest upon stratified clay sands and volcanic tufa, which contain marine fossil shells, all or nearly all of which are identical with species now inhabiting the Mediterranean. These strata form a series of hills 600 to 800 feet in height, which extend along the southern margin of the mountain. They indicate that the bed of the sea has during the existence of the present testacea been raised several hundred feet above its ancient level. The sedimentary

strata, and the limestone of the newer pliocene period upon which they rest, define the origin of the flows of lava to be within this very recent period in the history of the formations which compose the crust of the earth. Were there data furnished by long kept records, by which the average rate of increase of volcanoes could be determined, the application of these to the case of Etna might furnish some approximation toward the time that has passed while its 10,000 feet or more of layers of lava have been accumulating. But the recorded observations of the action of volcanoes are too incomplete, and this action is too variable in its nature, for any data we possess to shed light upon this question. A single volcano, as that of Jorullo in Mexico, with thousands of little cones about it, is known to have risen at once to the height of more than 500 feet; while another, as that of Ischia, is known to have lain dormant with no increase of its dimensions for 17 centuries. The only data, therefore, upon which any calculation of this sort can be based, must be furnished by what we know of the structure and history of the volcano itself. Upon the eastern side of the mountain is a remarkable valley 4 or 5 miles wide, called Val del Bove, which extends far in toward the centre, and presents on each side precipitous walls, that attain at the upper extremity a height exceeding 3,000 feet. A section furnished by these walls, and the naked conical peak 1,000 feet high, expose the structure of nearly half the height of the mountain. All this consists of alternating beds of lava and of breccia, or broken fragments of lava, which appear each to have been produced by a flow of the liquid material deposited upon the older layer beneath it. All these layers incline toward the sea, as if the currents had uniformly flowed in that direction. Through these piles of stratified lava many of the secondary cones are seen projecting, and in such relation to the layers that it is apparent they were thrust up subsequently to the consolidation of these. Turning now to the historical records, there is nothing found in them which would lead to the opinion that the altitude of the mountain has materially varied within the last 2,000 years. Of the 80 cones previously referred to as seen upon its flanks, only one, Monti Rossi, has been produced within this time. It is hence reasonable to suppose that a great many centuries elapsed while these cones were produced. If we go back to the period of the origin of the oldest among them, the long series of the stratified lava beds of the Val del Bove lie beneath these, and other series of more ancient cones still are found buried under these strata which flowed around and concealed them from view. "In the deep sections of the Val del Bove nothing seems to indicate that the ancient lava currents exceeded in dimensions those of modern times; and there are abundant proofs that the countless beds of solid rock and scorïæ were accumulated, as now, in succession. On the grounds therefore already explained, we must infer that

a mass so many thousand feet in thickness must have required an immense series of ages anterior to our historical periods for its growth; yet the whole must be regarded as the product of a modern portion of the tertiary epoch." (Lyell's "Principles," ch. xxv.)

ETON, a town of Buckinghamshire, England, on the left bank of the Thames, opposite Windsor, 22 m. W. from London by road; pop. in 1851, 3,666. Its college, the most celebrated of English public schools, was founded by King Henry VI. in 1440, and endowed by a gift from his own demesne lands and those belonging to some priories whose revenues had been appropriated to religious houses abroad. The original foundation consisted of one provost, 10 priests or fellows, 4 clerks, 6 choristers, one master, 25 poor scholars, and as many poor men, or beadsmen. Henry VI. intended it as a seminary for a college in one of the universities, and therefore founded, contemporaneously with Eton, King's college, Cambridge, to which Eton was to be preparatory. The first stone of the building was laid July 8, 1441. In 1448 Henry VI. increased the number of scholars to 70 and reduced the beadsmen to 18. At present the foundation consists of a provost appointed by the crown, a vice-provost, 6 fellows, 2 chaplains called conducts, 10 lay clerks, 10 choristers, beside inferior officers and servants, and 70 scholars, who since the reign of George III. have been called "king's scholars." As Eton was a Lancastrian foundation, it suffered under the rule of the house of York, and was curtailed by Edward IV. of many of its possessions. More fortunate under the Tudors, Eton was specially excepted from the act of parliament passed in the time of Henry VIII. for the dissolution of colleges and chantries. At this period its revenues were estimated at £1,100. In 1506, the total income was £652. Its present income is about £7,000. The college buildings consist of 2 quadrangles, built partly of freestone, but chiefly of brick. The scholars on the foundation are lodged and boarded in the college, and by way of distinction are called collegers. They are admissible from the age of 8 to 16, and unless put on the roll for admission to King's college at 17, are superannuated and obliged to leave at 18. If put on the roll, they may continue till 19. The foundation scholars must be born in England and of parents lawfully married. By the statutes they should be instructed gratis and clothed in some coarse uniform, but in neither of these points are the statutes adhered to. A small sum of £6 or £7 per annum is charged to the parents of every foundation scholar who are able to pay it. Every year the 12 head boys are put on the roll of King's college, but continue at Eton until there is a vacancy or until superannuated. At King's college the Etonians are maintained free of expense, and after 8 years they succeed to fellowships. On an average 4 scholars go to King's college yearly. There are also 2 scholarships at Merton college, Oxford, for foundation scholars who are not elected for

King's college. These latter are called *portionists*, or by corruption, postmasters. In 1842 Prince Albert instituted an annual prize of £50 for proficiency in the modern languages. The larger number of Etonians are not on the foundation, and are called oppidans. They do not board in the college. The annual expenses of an oppidan amount to about £150 or £200. The 6th form is the highest in the school, and is limited in number to 22. Of these the 10 highest are styled monitors. The head boy is called "the captain." The classes are divided between the lower and upper school. There are a head master and a lower master, 12 assistant masters in the upper school and 4 in the lower school, beside a mathematical master. There are also masters of the French, German, and Italian languages. The course of instruction is almost wholly classical; mathematics and the modern languages are only studied in extra hours. The annual elections take place in the last days of July every year. At the elections of 1858, the total number of collegers and oppidans was 757, being an increase of 26 over the year previous. In 1764, at which period the school was very prosperous, the number of boys amounted to 516. The black hat and the white neckerchief are distinguishing marks of an Eton boy's costume. The system of fagging, by which the boys in the lower school are subject to the orders of the members of the 6th form, is in full vigor at Eton. The Eton montem was a peculiar ceremony, formerly biennial, but after 1759 held triennially on Whit-Tuesday, and discontinued since 1844. On this occasion the boys marched in procession about 1½ m. to an elevation on the Bath road called Salt hill, under the lead of the head boy of the foundation scholars as captain. Here they spent the day, partook of a bountiful breakfast and dinner, with music and various ceremonies, and collected toll from all spectators and passers-by. The scene was visited by great numbers of people, and even sometimes by the royal family, and the contributions, called salt, have been known to exceed £1,000. After deducting expenses, the remainder was paid over to the captain, who in 1847 was indemnified by the queen for his loss by the omission of the ceremony. Among the celebrated men educated here may be mentioned John Hales, the poet Waller, Sir Robert Walpole, Harley, earl of Oxford, Lord Bolingbroke, Earl Camden, the earl of Oatham, the Hon. Robert Boyle, Lord Lytton, the poet Gray, Horace Walpole, Stevens the editor of Shakespeare, Fox, Canning, the marquis of Wellesley, the duke of Wellington, Henry Hallam, and Lord Derby.

ETRURIA, or TUSCIA (called by the Greeks *Tyrrhenia*), a division of ancient Italy, bounded W. by the Tyrrhenian sea, and separated on the N. W. from Liguria by the river Macra, N. E. by the Apennines from Cispadine Gaul, E. and S. by the Tiber from Umbria and Latium. It was a fertile and well cultivated country. Its chief rivers were the Tiber and the Arnus (now Arno); its chief lakes the Thrasymenus (now lake of Pe-

rugia), renowned for one of the great victories of Hannibal, the Vadimonis (Bassano), the Volsiniensis (Bolsena), and the Sabatinus (Brocciano.) Of its mountains, the Ciminus (Monte di Viterbo) and Soracte (Monte di San Oreste) are often mentioned. The testimony of ancient writers, and late discoveries of antique monuments, comprising walls, *cloacæ*, tombs adorned with sculptures, vases, coins, &c., prove that Etruria was inhabited by a civilized and cultivated people long before the foundation of Rome. They were called Etrusci or Tusci by the Romans, Tyrrheni or Tyrseni by the Greeks. Their national name was Rasena. They were regarded as autochthones by some of the ancient historians, and by Herodotus as descendants of a colony from Lydia, led there by Tyrsenus, son of Atys, an ancient king of that country. The authenticity of this story, however, though corroborated by Dionysius, is rendered doubtful by the circumstance that Xanthus, the national historian of Lydia, ignores both the expedition and the name of the prince its leader. The relation of Herodotus is now generally believed to have been one of those mythical legends in which the earliest history of the ancient nations is wrapped, and to have represented the common Pelasgian origin of the primitive inhabitants of Lydia and Etruria. But there is sufficient ground to believe that these Pelasgian Etruscans, the relatives of the Umbrians, Oscii, Siculi, and other ancient Italian tribes, received a part of their culture, which became the source of that of the Romans, by subsequent importations from the countries of the East, from Egypt, Phœnicia, or Asia Minor. According to Mr. Layard, several representations on the Etruscan monuments bear no little resemblance to the lately discovered works of the Assyrians. The influence of Grecian art and civilization upon the Etruscans is evident, and it can easily be proved that it continued to be exercised even at the period which followed the foundation of Rome. It is now generally supposed that the Rasena immigrated from the north, probably from Rhætia, now the Tyrol, and subdued the more ancient Pelasgians, Etruscans, Tuscans, or Tyrrhenians, with whom they were finally blended into one powerful and flourishing nation. In Etruria they formed a confederacy of 12 cities with adjacent districts, which are supposed to have been the following: Cære (now Cerveteri, Old Cære), Tarquinii, in Roman history the suburb of the Tarquins, Rusellæ (Roselle, remarkable for its monuments), Vetulonia (Torre Vecchia), Volaterræ (Volterra), known as a watering place, Arretium (Arezzo), Cortona (Cotrone), Perusia (Perugia), Volsinii (Bolsena), Falerii (Falari), known by the siege of Camillus, Veii (Isola Farnese), the neighbor and long rival of Rome, taken by Camillus after a siege of 10 years at the beginning of the 4th century B. C., and Clusium (Chiusi), the seat of King Porsena. Other important places of Etruria were: Pisæ (Pisa), founded according to a legend by wandering companions of

Nestor from Pisa in Elis; Fæsulæ (Fiesole), near which Catiline was defeated, 62 B. C.; Populonia, known for its coins; Luna, Volci, &c. Beyond the limits of their country they possessed the land on both sides of the Po, from the Ticino to Bologna, called by them Felsina. This country, which they conquered at the time of their immigration into Italy, or shortly after, and which was divided into 12 equal districts, was afterward taken from them by the Gauls. They had flourishing colonies in Corsica, Ilva (Elba), and in Campania, where they are supposed to have founded (about 800 B. C.) a confederacy similar to that of Etruria. Their navy was powerful on the Mediterranean at a very early period; a legend mentions an attack upon the Argo, the ship of the Argonauts, by Tyrrhenian mariners. Their commercial vessels visited the eastern shores of the Mediterranean. The inhabitants of Cære were dreaded as pirates. The growth of their commerce, as well as of their power on land and sea, was followed by a rapid development of industry and art, refinement and luxury, in their cities. Their coins in bronze, their urns and sculptures, are proofs of their great proficiency in the arts; the frequently occurring representations of festive entertainments, games, races, and dances, accompanied by music, prove their love of recreation, no doubt fostered by the mildness of their beautiful climate. They also had national assemblies for religious and political purposes, celebrated at the temple of Voltumna in Volsinii. Their religion resembled in most of its conceptions the polytheism of the Greeks and Romans; it appears, however, to have been deeper, gloomier, and less fanciful than that of the former. The names of many of their deities, who were divided into higher or hidden and other gods, and were believed to reside in the remotest north—a notion current among the Assyrians and other Asiatic nations (Isaiah xiv. 13)—seem to mark the transition from the Grecian to the Roman forms. Tina (Jupiter), by some critics compared with Ζην, the root of Zeus, Ζηνος, presides over the council of 12 *consentes* or *complices*, probably personifications of the 12 constellations of the zodiac. They had lunar and solar divisions of time, and cycles of more than a century. Of their numerous sacred books, the principal of which were believed to contain the revelations of the demon Tages, the so called Acherontic taught how to propitiate the gods, to delay fate, and to deify the soul. Many of their religious rites, those of augury for instance, were adopted by the Romans, who also imitated their games, insignia, and triumphal distinctions. Their priests, called *lucumos*, appear at the same time as heads of noble families, and as kings or rulers of cities. They formed the senate of the confederacy, which seems to have consisted of loosely connected independent and sovereign members, at a later period ruled by magistrates chosen annually. The common people were dependent upon the priestly aristocratic families

in a kind of feudal clientship, whose forms appear more servile than in the similar Roman institution. Freemen also occur in the history of some of the confederate cities, but as a politically unimportant class.—The most flourishing period of the history of Etruria comprises about 8 centuries before and as many after the foundation of Rome. Through the Tarquins, who were Etruscans, they may have even exercised a kind of dominion over their younger neighbor, as some modern critics suppose. Porsena, king of Clusium, who made war on Rome for the restoration of Tarquin the Proud, compelled the Romans to a humiliating treaty. But scarcely had Rome gained peace from him when it commenced war with another Etruscan enemy, Veii (485 B. C.). This war, often interrupted by truces, lasted for 90 years, and ended with the fall of the Etruscan state, owing probably to the distraction of the confederacy during the same period by frequent, successful, and devastating incursions of the Syracusans, by attacks of the Samnites upon its Campanian dependencies, and by the threatening advance of its northern neighbors, the Gauls. After the invasion of the latter under Brennus, the Ciminian forest was for some time the boundary between Etruria and the land of the Romans. This was however soon passed by the conquerors of Veii and Falerii, and the two battles fought near the Vadimonian lake, by Quintus Fabius (310) and Publius Cornelius Dolabella (283), finally broke the power of Etruria. The social relation to Rome, into which it entered in 280 B. C., was changed after the social war, in reward for its fidelity, into Roman citizenship. Soon afterward Etruria suffered greatly from the revenge taken by Sylla on the partisans of Marius in its cities. Whole districts were given as confiscated estates to the veterans of the dictator, who afterward became the accomplices of Catiline (68–62). Octavianus, too, had his military colonies in Etruria. The history of modern Etruria, a kingdom created by Napoleon in 1801, and given to Louis, crown prince of Parma, ruled after his death by his widow Maria Luisa of Spain as regent, and in 1807 annexed to France as a province, belongs to that of Tuscany (a name derived from the Roman *Tuscia*). Among the numerous writers who have treated of the antiquities of Etruria, the most instructive are Lanzi, Inghirami, Niebuhr, Ottfried Müller, Hey, Wachsmuth, Hornmayer, Steub, Dorow, Micali, Abeken, Seck, Lepsius, Gerhardt, Bunsen, and Witte.

ETRUSCAN LANGUAGE, the language of the ancient Etrurians. Dionysius of Halicarnassus and Bochart regard the Etruscan as an aboriginal language; Fréret makes it Celtic, Ciampi and J. Kollar Slavonic, Micali Albanese; L. Lanzi derives it from the Greek and Latin, and holds that the Umbrian, Volscian, Oscian, and Samnitic are dialects of it; O. Müller thinks it akin to the Greek; others derive it from Rhætia; and finally, Lami, Pfitzmaier, and others, suppose it to be Semitic, a hypo-

thesis which in 1858 J. G. Stickel demonstrated to be the truth. Its alphabet consists of 21 letters, almost coincident in form with the ancient Greek letters, written from right to left, but corresponding in value to those of the Hebrew, though not used as numeral signs. The element *d* and the Hebrew *samech* are wanting; *g* and the Hebrew *tsade* seldom occur; but the *q*, taken from the Greek *γ*, exists, though wanting in the Hebrew. The Semitic aspirates and gutturals are much softened, and consonants melt into their kindred vowels, the latter being mostly written instead of being indicated by their diacritic points. Guttural sounds are not, however, altogether abolished. *T* takes the place of *d*, and cognate letters are freely interchanged. We subjoin some examples of Greek and Latin words in their Etruscan forms: *Tarchna*, *Meurva*, *Menla*, *Paltuka*, *Elasentre*, *Utuse*, *Itus*, *Hatri*, &c., for Tarquinius, Minerva, Menelaus, Polydames, Alexandros, Odysseus, Idus, Adria, &c. The orthography is more fixed than that of the other ancient Italian languages. Pliny says that the Etruscan writing was prior to the building of Rome, but its origin is not yet ascertained. L. Bourget discovered 16 epigraphic letters, and determined the value of several of them; Lanzi found 8 more, and Montani one. There are few words which are analogous to the Greek or Latin, the terminal *s* being dropped, and *e* being the most frequent ending; thus, *Pela*, *Tuta*, are Etruscan for Pelena, Tydæos. The language is poor in particles and simple in construction. There are few words which cannot be reduced to Hebrew, Chaldaic, or Arabic originals. But few of the numeral words and figures are yet known, viz.: 5 (*hems*), written with the inverted sign of 50 (*hemsim*), which is the initial of this word, somewhat modified to form a Latin *V*; 10 (*tesen*, from a Sanscrit root), written with the sign of *t*, a cross, whence the Latin *X* (unless this be two *V*s combined); 100 (*t'at*, Slavic *sad*), written with the sign of *t* final; and 1,000 (*akep*), written with the sign of *b*. The following are specimens of proper nouns: *Turvas* (rock, castle, town), whence Greek *Τυρῖνος*; *Atri* (hedged in, court, wall, confluence), whence Adria, *atrium*, and most likely *Etr-usq* (wall-strong, fort-builder); *Mantuha* (wet place), whence Mantua, one of the 12 cities of Cispadane Etruria, which was the last to fall into the power of the Celts; *Agylla* (roundness), later *Care* (*gere*, city); *Tarchna* (roadstead, or way for ships). The termination *al*, taken for a patronymic sign, signifies "risen, rising;" it is found in many proper nouns, such as *Ceional*, *Cefnal* (*Cilnia gentis*, to which Mæcenas belonged, a Mæcnatium on his mother's side), *Leional*, *Larthal*, &c.; *sa* final is supposed to denote the name of a married woman by modifying that of the husband (like the German *inn* and the Slavic *a*), as *Lecne-sa*, the wife of Licinia. Among Etruscan words and phrases are *itus* (*itis*, day), *idus*, day of the full moon; *asar* (hidd. god; *nepos* (greediness), squanderer; *histu* (*u*, staggering), whence

histrio, one who gesticulates, an actor; *lana* (colored), a tunic; *lucumo* (possessed by a spirit), a Tuscan prince; *lituus* (bent), staff of the augurs; *lara*, protecting divinity; *sez*, daughter; *gil* (rolling, swift), year (some read *ril*, owing to the identity of the sign for both *q* and *r* in the great Perusian inscription); *skal*, lion; *lla*, lamb; *us*, altered into; *tinsk fil*, bites terribly; *afeti*, I rest, my peace; *toufles*, thou risest fire-like. Of the 9 inscriptions explained by Stickel, the greatest is that on the square sepulchral stone discovered in 1822 and preserved at Perugia. It has 24 lines in front and 21 on one of the other sides, containing 658 letters. It is a monument of the expulsion of 12 and afterward of 10 *Rasne* (Etruscans) by the Veltnas from the Apennines into the lower country, and of the occupation of the lands so vacated by the *Clensi* (Clusii), about the time of the foundation of Rome. That on the pallium of a man "deprived of eyes" by a Clusian about the time of Porsena (506 B. C.); the tablet represents "an old man being tied to a tree, preparatory to being flayed" alive. Of several hundred short funeral inscriptions known, 17 have been published as proofs of the Semitic character of the language; some of them are bilingual, with a Latin part giving the name of the deceased, while the Tuscan expresses such sentences as: "While we depart to naught our essence ascends;" "We rise like a kite," &c. Out of 10 mementoes of funeral sacrifices we quote the following: "Raise the soul as fire! it departs for ever;" "We ascend to our ancestors." Beside sepulchral urns, there are inscriptions on candelabra, drinking cups, and other utensils, all of great antiquity, testifying the efficiency of the Tuscans in the arts, independent of the Greek imitations of their works. Some of these monuments have been found in Campania, some in Etruria proper, and in other countries formerly inhabited by Etrurians. One occurs as far N. E. as Carinthia, on a mossy rock in a forest near Wurumbach; it runs thus: *Koc'e'tiuoifla nzirios'igtib* ("Bring hither the weary at seeing this writing"). This inscription appears to be of later date than any other. Of inscriptions on coins there are but few. Under the Roman emperors the haruspices used Latin versions of Etruscan rituals. Such were the *libri Etrusci*, *Etrusca disciplina* (religion); rituals on the manner of building cities, temples, and altars; on the sanctity of walls and gates; on the *tribus*, *curia*, military order, &c.; *fulgurales* and *haruspicini*, and the *prodigia*; *Tagetici*, on the ceremonies (*caremonia*, from *Care* or *Agylla*) of the earth-born god Tages; *acheruntici*, on conciliation with the gods, &c. There were also ancient pastoral and augural songs. Varro preserved some fragments, and mentions Etruscan tragedies by Volumnius. The scoffing and jocular Fescennine (so called from Fescennium, a city of Etruria) and Saturnalian verses were also derived from the Tuscans. Cicero, Aulus Gellius, Cæcina, Nigidius Figulus, and some later Romans translated and explained

various Etruscan books, of which we have but fragments.—In addition to the authorities mentioned above and in the article on ETRURIA, see Gori, *Difesa dell' alfabeto degli antichi Toscani* (Florence, 1742); J. C. Amaduzzi, *Alphabetum Veterum Etruscorum* (Rome, 1775); G. B. Vermiglioli, *Saggio di congetture, &c.* (1824); J. Kollar, *Staroitalia Slavjanska* (Vienna, 1858); Mommsen, *Nord-Etruskische Alphabete*; Dempster, *De Etruria Regali* (Florence, 1723-'4); Winckelmann (on art), Uhden, and Dr. Frick, in archæological and philological periodicals.

ETTY, WILLIAM, an English painter, born in York, March 10, 1787, died there, Nov. 13, 1849. He was the son of a baker, and at the age of 12 was apprenticed to a printer at Hull, with whom he remained 7 years. In 1807 he was admitted a student in the royal academy, and was also a private pupil of Sir Thomas Lawrence for a year. He repeatedly sent pictures to the exhibitions of the royal academy and the British gallery, which were rejected. In much despondency he sought the advice of his old master, who told him that he had a good eye for color, but was lamentably deficient in all other respects. Profiting by this hint, Etty worked harder than ever, and in 1811 had the satisfaction to see one of his pictures on the academy's walls. By degrees he succeeded in building up a reputation, and in 1821 his "Cleopatra's Arrival at Cilicia," in which the nude female form was depicted with great correctness, and with a voluptuous glow of color, brought him into considerable notice. In 1822 he went to Italy, and spent many months in the study of the Venetian colorists. In 1848 an exhibition of his works was opened in London, prominent among which were the 9 great paintings which he considered the triumphs of his artistic career, and in which he says he aimed "to paint some great moral on the heart." They comprise "The Combat," the 3 "Judith" pictures, "Benaiah, David's Chief Captain," "Ulysses and the Sirens," and the 3 pictures of "Joan of Arc." Etty is considered one of the chief artists of the modern English school. His life has been written by A. Gilchrist (2 vols. 8vo., London, 1855.)

ETYMOLOGY. See LANGUAGE.

EUBŒA. See NEGROPONT.

EUBULIDES OF MILETUS, the best known of the disciples of Euclid of Megara, flourished about the middle of the 4th century B. C. His life was a struggle against Aristotle, in which by a captious logic he sought to prevail against good sense. A partisan of the Megaric principle, that there is nothing real but what is always one, simple, and identical, he immediately found an adversary in the founder of the great contemporary school which made experience the condition of science. He attacked the peripatetic doctrine, like Zeno of Elea, by striving to show that there is none of our experimental notions which does not give place to insolvable difficulties. To this end he invented his famous sophisms, of which the following is a specimen: "Some one lies, and says that he lies. Does

he lie, or not? By the hypothesis, he lies. Then he does not lie, for what he says is true. Thus he lies and does not lie at the same time, which is contradictory."

EUBULUS, an Athenian poet of the middle comedy, flourished about 376 B. C. He wrote 104 plays, chiefly on mythological subjects, many of them containing parodies of passages from the tragedians. The fragments of his works which remain have been edited by Meineke, and are marked by a peculiarly pure diction.

EUCHARIST (Gr. *eucharistia*, thanksgiving), a name frequently given to the sacrament of the Lord's supper, either in allusion to the praises with which the early Christians used to celebrate it, or because at its institution our Saviour "gave thanks" in blessing the bread and wine. (See LORD'S SUPPER.)

EUCLID, the most celebrated of ancient geometers, flourished at Alexandria, in the reign of the first Ptolemy, in the 3d century B. C. The Arabic historians give many unauthenticated particulars of his life; but it is only certain that he dwelt first in Greece and then in Egypt, and probable that he studied at Athens under the successors of Plato, and then passed over to Alexandria. There he founded the mathematical school, and was remarkable for his zeal in science, his affection for learned men, and his gentle and modest deportment. Ptolemy having asked him if geometry could not be made easier, he made the celebrated answer that there was no royal road to geometry. To appreciate the merit of Euclid, the state of geometry before him should be considered. Proclus gives the improbable legend that the Egyptians were obliged to invent geometry in order to find again the boundaries of their fields, effaced by the inundations of the Nile. Thence it was brought to Greece by Thales, but it was first raised to a liberal science, and applied to the solution of speculative and theoretical problems, by Pythagoras. Hippocrates was the first to write on elements. Plato, without writing particularly upon geometry, contributed much to its progress by his use of the analytic method, and by the mathematical style of his books, and new theorems were added by numerous lesser philosophers. At the advent of Euclid, something had been written on proportion, incommensurables, loci, solida, and perhaps conic sections; and the important property of the right-angled triangle had been discovered. It was the glory of Euclid to unite in a single book all the discoveries of his predecessors, and to add several new ones of his own. He surpassed all other geometers of antiquity in the clear exposition of his theorems and the rigid order of his demonstrations. The "Elements" of Euclid belong both to geometry and arithmetic. They consist of 13 books written by Euclid, and 2 others written probably by Hypsicles; and they may be divided into 4 parts, of which the 1st, comprising the first 6 books, treats of the properties of plane figures, and presents the theory of proportions; the 2d gives, in the 3 following books,

the general properties of numbers; the 8d, consisting of the 10th book, is the development of all the power of the preceding ones, and is occupied with a curious and profound theory of incommensurable quantities; and the remaining books are on the elements of solid geometry, and were so much studied among the Platonists as to receive the name of the Platonic. The best known of the treatises of Euclid, after the "Elements," is the "Data." By this name are designated certain known quantities which by means of analysis lead to the discovery of other quantities before unknown. One hundred propositions are here collected which are the most curious examples of geometrical analysis among the ancients. Newton highly valued them, and Montucla styles them the first step toward transcendental geometry.—The history of the works of Euclid is the history of geometry itself, both in Christian and Mohammedan countries, until after the revival of learning. They were commented upon by Theon and Proclus, and became the foundation of mathematical instruction in the school of Alexandria. Of the numerous editions and commentaries among the Orientals, that of Nasireddin, a Persian astronomer of the 13th century, was the best. The "Elements" were restored to Europe by translation from the Arabic, the first European who translated them being Adelard of Bath, who was alive in 1130, and who found his original among the Moors of Spain. Campanus, under whose name this translation was printed, was for a long time thought to be its author. The Greek text was first published in 1538 by Simon Gryncæus at Basel, and in subsequent editions was corrected by comparison of manuscripts. Since then the work has been published in a great variety of editions, and translated into all the European and many oriental languages. The English adaptations by Simson and Playfair have been widely received as text books in geometry.

EUCLID OF MEGARA, a disciple of Socrates, born about 440 B. C. His first master was Parmenides; afterward he became a devoted disciple of Socrates, at whose death, according to Plato, he was present. But notwithstanding his affection for his second teacher, he retained from the Eleatic school an invincible tendency to subtlety, and it was said of him by Socrates that he knew how to live with sophists, but not with men. After the death of Socrates, his disciples, fearing for their lives, fled from Athens; and at Megara, in the house of Euclid, they found an asylum and a new centre for their studies. Plato himself was an ardent attendant upon Euclid, who taught that the essence of good was unity, unity so entire as to embrace immobility, identity, and permanence. Hence the sensible world has no moral character and no relation to good. He taught also that being consists only in unity, identity, and permanence, and hence the sensible world has no part in existence. Being and good are thus the same thing, namely, unity; good therefore alone exists, and evil is but the absence of existence.

It does not follow, however, that there is but a single being and a single sort of good, for unity may be found contained in various things. Euclid expressly taught that in spite of their unity, being and good clothe themselves in different forms, present themselves under different points of view, and receive different names, as wisdom, God, intelligence, and others. Euclid also anticipated Aristotle in distinguishing the act from the power, and resolved according to his ideas of being the relation between the two.

EUDIOMETER (Gr. *eudia*, pure air, and *μετρον*, measure), the name given to an instrument invented by Priestley for determining the proportion of oxygen in the air, in the belief that on this depended its salubrity. Many other instruments have since been invented for estimating the amount of oxygen in gaseous mixtures, and the name is retained for these, though it has no longer its original significance. In the application of the instrument for estimating oxygen, the gas is made to unite with some substance, as phosphorus, introduced into the gaseous mixture, which is contained in the upper end of a graduated glass tube inverted over mercury. The diminution of bulk caused by the absorption of the oxygen indicates its quantity. In other forms a known quantity of hydrogen is introduced and the mixture fired by an electric spark produced by means of two wires being melted into the sides of the tube and nearly meeting each other within. In this case the tube is made very thick to withstand the explosion. Every two volumes of hydrogen consume one of oxygen, whence the quantity of the latter may be estimated.

EUDOCIA, originally named **ATHENAI**, a Grecian maiden, who became the wife of the emperor Theodosius II., born in Athens about A. D. 394, died in Jerusalem about 461. She was instructed by her father, the sophist Leontinus, in the religion, literature, and science of the pagan Greeks, and was as remarkable for her personal beauty as for her learning. Leontinus at his death divided his property among his sons, saying that the merits of his daughter (to whom he left only 100 pieces of gold), which raised her so much above her sex, would be sufficient for her. Thus disinherited, and having sought in vain from her brothers a share in the paternal heritage, she went with an aunt to Constantinople to solicit the cancelling of the will. She procured an audience of Pulcheria, sister of the young emperor Theodosius II., and regent in his name, who was so charmed by her wit and beauty that she secretly destined Athenais to be the wife of her brother. Theodosius himself, then 20 years of age, was captivated at the first interview, and Athenais renounced the religion of her father, was baptized by the patriarch of Constantinople, from whom she received the name of Eudocia, and was married to the emperor in 421. She received the title of Augusta in 423, after having given birth to a daughter, and she requited the unkindness of her brothers by making them consuls and prefects. During

the first 20 years after her marriage Eudocia took little part in public affairs, which remained in the hands of Pulcheria. She translated parts of the Old Testament into hexameter verses, and a life of Jesus Christ composed in verses taken from Homer is attributed to her. She also celebrated in verse the Persian victories of Theodosius, and the legends and martyrdom of Saint Cyprian. She at length supplanted Pulcheria, and ruled the empire for 7 years, from 448 to 450. Her court was filled with learned men, with one of whom, Paulinus, a companion of her early studies in Athens, she cherished an intimacy which roused the jealousy of her husband, and Paulinus was banished to Cappadocia, where he was soon afterward assassinated. The Eutychian discussion was now vexing the church; Pulcheria and Eudocia adopted different views, and in the alternate ascendancy of the two parties, first the former and then the latter was exiled. Eudocia retreated to Jerusalem, where, however, the jealousy of the emperor or the vindictive spirit of Pulcheria pursued her, and two priests who shared her exile were slain. The exasperated empress immediately put to death the agent of the emperor; and being now stripped of all the honors of her rank, she passed the remainder of her life in exercises of piety and charity. The influence of St. Simeon Stylites and of Euthymius, another eminent ascetic, induced her at last to abandon Eutychianism. She died protesting to the last the innocence of her life.

EUDOXIA, daughter of Theodosius II. and Eudocia, born in Constantinople in 422, died about 463. She was married to her cousin Valentinian III., emperor of the West, after whose death, by the hands of emissaries of the senator Maximus, she was constrained to espouse the latter. Maximus subsequently had the folly to reveal to her the part which he had taken in the murder of Valentinian, and when the time for vengeance seemed to her to have come she invited to Italy Genseric, king of the Vandals, at whose approach Maximus was murdered. Genseric delivered Rome to pillage, and bore away with him to Africa Eudoxia and her two daughters. They were released after a detention of 7 years, during which one of the daughters was forced to marry the son of Genseric.

EUDOXUS OF CNIDUS, a Greek natural philosopher, born about 409, died about 356 B. C. He studied under Archytas and Plato, travelled in Egypt, and returned to Cnidus in 359, founded a school, and built an astronomical observatory. Though he seems to have treated the whole circle of the sciences, he particularly excelled in geometry and astronomy, and is called by Cicero the prince of astronomers. In his astronomical system the earth was the motionless centre of all the celestial revolutions. The movements of the sun, moon, and 5 planets resulted, according to him, from the combined revolutions of concentric spheres, of which there were 3 each for the sun and moon, and 4 for each of the planets. Every planet occupied a

part of the heavens by itself, and was surrounded by moving spheres, whose mutually modified motions made the orbit of the planet. He first fixed the length of the year as adopted in the Julian calendar at 365½ days, and introduced celestial spheres or globes. In music he studied the numerical relations of sound according to the rapidity of the vibration of the chords. In arithmetic he added 3 kinds of proportion to the 3 kinds known before him.

EUDOXUS OF OZYRIA, a Greek navigator of the 2d century B. C. Expeditions from Egypt to India had for a time ceased, when he revived them under the reign of Ptolemy Evergetes. His bold enterprise in seeking the most direct route to India, to which he made two voyages, and whence he seems to have been the first to bring diamonds, and in attempting to circumnavigate Africa by the west, caused him many persecutions, and his reputation has been obscured by the fables with which Nepos and Mela sought to embellish it.

EUFAULA, a post village of Barbour co., Ala., beautifully situated on the right bank of the Chattahoochee river; pop. in 1852, 2,000. It stands on a high bluff, 200 feet above the water, and contains several churches and newspaper offices, and many stores. An active and constantly increasing trade is carried on by means of the river, which is navigable to this point from November to June. It is the principal shipping point for the produce of the surrounding plantations, and exports annually about 20,000 bales of cotton.

EUGENE, FRANÇOIS, called Prince Eugene of Savoy, born in Paris, Oct. 18, 1663, died in Vienna, April 21, 1736. His parents were Eugene Maurice, count of Soissons, a grandson of Charles Emmanuel I., duke of Savoy, and Olympia Mancini, one of the nieces of Cardinal Mazarin. He was intended for the church, in which he had no taste, but devoted himself to military reading. Louis XIV. refused him a regiment, and he encountered the enmity of Louvois—a refusal and an enmity that was to cost France dear. He entered the Austrian service, and made his first campaign against the Turks in 1683, so distinguishing himself that he was promoted to the command of a dragon regiment. He was present at the battle of Vienna. Further service led to further promotion, and he held the rank of major-general at the siege of Belgrade, in 1688. Louvois now required all Frenchmen serving in foreign armies to return home, on pain of banishment. Eugene refused to obey, and declaring that he would return to France in spite of the minister, remained in the imperial service. He was sent to Savoy in a diplomatic capacity, but he served as a soldier under the duke of that country in several campaigns, being his lieutenant when he invaded France in 1692. He was brevetted field marshal, and after his return to Vienna was placed at the head of the army in Hungary. Sensible of the folly he had committed, Louis XIV. now made him general, offers on condition

of his entering the French service. These offers he would not listen to, but took command of an army that was employed against the Turks. He completely outgeneralled the enemy and exterminated their army at Zentha, Sept. 11, 1697, winning one of the greatest victories of that age. The action was fought in violation of orders, which his enemies at court turned to account. He was placed under arrest, and it was intended to send him before a council of war; but the emperor changed his mind and restored him to his command. He accomplished nothing more of importance, and peace was made in 1699. When the war of the Spanish succession commenced in 1701, Eugene was sent to Italy, where he showed himself superior to Catinat, and won great successes. Villeroi, Catinat's successor, he defeated at Chiari, and compelled him to abandon the territory of Mantua. In Jan. 1702, he attacked the French in Cremona, and though repulsed, captured their general. In Vendôme he found a worthy antagonist, and they fought the bloody drawn battle of Luzara, Aug. 1, 1702. Appointed president of the war council, and afterward sent against the Hungarians, Eugene did nothing more equal to his reputation until 1704, when he first served in company with Marlborough. They fought and won the battle of Blenheim, Aug. 13, Eugene's part in the action being important. He was then sent to Italy, and was defeated at Cassano (Aug. 16, 1705) by Vendôme, being twice wounded. When the French army passed into the hands of the duke of Orleans and Marshal Marsin, and were engaged in besieging Turin, Eugene, at the head of only 30,000 men, attacked their 80,000 men, and defeated them, Sept. 7, 1706. He was wounded in the action. He was rewarded with the government of the Milanese. The next year he made an attempt upon Toulon, but failed. He was then employed at the German court in hastening preparations for the next campaign; and in that campaign he helped Marlborough to win the battle of Oudenarde, and took Lille. He was at the battle of Malplaquet, Sept. 11, 1709, and aided to gain the field for the allies. On the decline of Marlborough's power in 1711, he visited England, hoping to gain her back to her former position in the alliance, but ineffectually. His own exertions against the French were fruitless, and in 1714 the peace of Rastadt put an end to the war between the empire and France. After residing at Vienna for some time, where he was much consulted by the emperor, he was appointed to the command of the army that was to act against the Turks, Austria aiding the Venetians in accordance with Eugene's recommendation. He defeated them at Peterwardein, Aug. 5, 1716, with immense slaughter. The next year he advanced against Belgrade, and was there assailed by very superior forces, some accounts say 6 to 1; but at a time when his destruction was regarded as inevitable he assailed the enemy, and inflicted upon them the greatest defeat they ever experienced, Aug. 16, and took the city on the 22d.

He was wounded in the battle. In 1718 he hoped to dictate peace at Constantinople, but the treaty of Passarovitz stopped his career of conquest. He was rewarded by a pension, an estate worth 300,000 florins per annum, and the vicar-generalship of Italy, having previously occupied the office of governor of the Netherlands. He held for many years nearly the same position in Austria that Wellington subsequently held in England. Yet he had bitter enemies, toward whom he was very forbearing. "His even temper," says Vehse, "never forsook him for a moment. He bore all the intrigues of his enemies, as well as their open and clumsy attacks, with imperturbable equanimity and patience; and showed himself so forbearing to his colleagues in the field and in the cabinet that not one case is known of his ever having taken revenge on his enemies." In many of his political opinions he was in advance of his age. He saw the error of the house of Austria in encouraging the growth of Prussia, and in conferring on her chief the royal title. He favored an alliance with France, thus anticipating the policy of Kaunitz. He fostered literature, science, and art, and corresponded with Boerhaave, Montesquieu, and Leibnitz, the last named being his personal friend; and he made great collections of MSS., books, and pictures. The last military service in which he was engaged was that which grew out of the war of the Polish succession, in 1734, when he commanded an army against the French on the Rhine. There was not much fighting and no pitched battle. The heir apparent to the Prussian crown, Prince Frederic, afterward Frederic II., then served under him, and the first hostile cannon he ever heard, at Philipsberg, were the last heard by Eugene. The future conqueror of Rossbach pronounced his commander to be only "the shadow of the great Eugene." He was found dead in his bed in the morning, after having played piquet the previous evening. His funeral was one of the most magnificent ever known, 16 field marshals carrying the coffin, and the emperor attending as a private mourner. He was never married, but he was supposed to have been the father of the two sons of the countess Batthyanyi. Eugene is considered one of the 5 greatest generals of modern times, the other 4 being Napoleon, Wellington, Marlborough, and Frederic the Great.

EUGÉNIE MARIE DE GUZMAN, countess of Teba, empress of France, born in Granada, Spain, May 5, 1826. She is the 2d daughter of the count of Montijo, a Spanish grandee, whose ancestors emigrated in the 14th century from Genoa to Spain. The ancestors of her mother, Marie Manuela Kirkpatrick of Closeburn, who was born in Andalusia, were Roman Catholics of Scotland, and fugitives from that country after the downfall of the Stuarts. The countess of Teba was educated in France and England, travelled extensively, and while in Paris (1851) she became acquainted with the present emperor of France, who married her,

Jan. 30, 1853. She was delivered of a son, Napoléon Eugène, March 16, 1856, the heir apparent of the French empire. She is remarkable for her beauty and accomplishments. On the emperor's departure for the seat of war in Italy, he appointed her regent, May 3, 1859.

EUGENIUS, the name of 4 popes. I. Born in Rome, died about 658. When Martin I. was banished by the emperor Constans II. in 654, Eugenius became vicar-general of the church, and in the same or the next year was chosen pope. He was distinguished for piety, and like his predecessor had trouble with the emperor. He was canonized. II. Born in Rome, succeeded Pascal I. in 824, died in 827. He was opposed by an anti-pope, and to quell the schism which followed, the emperor Louis the Good sent his son Lothaire to Rome. Eugenius held a council in which it was decreed that every bishop and clergyman should have in his house a master to teach the people and explain the Scriptures. He seems to have been a man of humility, simplicity, and learning, but is said to have countenanced the ordeal of cold water, instituted in his time, and condemned by the council of Worms in 829. III. Born in Pisa, succeeded Lucius II. in 1145, died in Tivoli, July 8, 1153. He was a Cistercian monk, a friend and disciple of St. Bernard, and assumed the tiara at a troubled period. His predecessor had been killed in a riot, the senate had declared its independence of the pope, a patrician had been chosen, and Arnold of Brescia was at the same time exciting the people by his preaching. The Romans demanded the pope's sanction to the acts of the senate, and Eugenius rather than yield retired to Viterbo almost immediately after his election. He enlisted the arms of the people of Tivoli, gained a partial success, and afterward went to France, where he held a council at Rheims in 1148, and another at Treves. With the assistance of Roger, king of Sicily, he subdued the Romans the following year and returned to his capital, but was again driven out and withdrew to Campania. In 1152 he made a compact with Frederic Barbarossa, but before the emperor could fulfil his promise to reinstate him at Rome the pope died. St. Bernard addressed to Eugenius his treatise *De Consideratione*. IV. **GABRIELE CONDOLMERO**, born in Venice, succeeded Martin V. in 1431, died in Rome, Feb. 23, 1447. He was a nephew, or according to some a son of Gregory XII., who was required to abdicate by the council of Constance. He was a Celestine monk, became bishop of Sienna, and was afterward cardinal and legate to Bologna. He was a man of impetuous temper, whose reign was unfortunately cast in a time which tried that temper to the utmost. One of his first acts in the pontificate was to charge the Colonnas, the nephews of his predecessor, with robbing the papal treasury; and having by this rash though probably just accusation gained the enmity of one of the most powerful families of Rome, he found himself, on the outbreak of a revolt in his states,

unable to raise either money or troops. The Colonnas paid dearly for their resistance to the demand for restitution. More than 200 of their partisans were put to death, and the arms, monuments, and dwelling of Martin V. were destroyed. The Colonnas called in the aid of the prince of Palestrina, who entered Rome at the head of an army; but Eugenius, having secured the help of Florence and Venice, beat him in a hard battle, and imposed his own terms upon the conquered. He now gave his attention to the Hussites and the council of Basel. The Hussites scattered his armies, but he would make no peace with them, and when news reached Rome that a truce had been concluded with the heretics he ordered it to be broken. With the council he had no less trouble than with the Hussites. Dec. 11, 1431, he published a bull dissolving the assembly, which was answered by a decree of the fathers, asserting their own supremacy over the pope, and summoning him to appear before them. After 2 years' delay, he was induced by the emperor to be present at the council. On the emperor's death quarrels broke out again, and Eugenius, having a second time dissolved the council of Basel, called a new synod at Ferrara. This produced a schism. A few prelates and many of the inferior clergy continued to sit at Basel, deposed the pope, and elected an anti-pope, Amadeus VIII., duke of Savoy, who took the name of Felix V. The schism lasted until after the death of Eugenius. The council of Ferrara gave its attention to a project for the union of the Greek and Latin churches, which the pope had much at heart. The emperor John Palæologus, the patriarch of Constantinople, and 21 bishops arrived at Ferrara in March, 1438, but a pestilence forced them to remove their sessions to Florence, where after much discussion the articles of union were agreed upon, July 6, 1439. The Greek people, however, never accepted the decree, and the separation between the churches continued in effect as wide as ever. Meanwhile Eugenius experienced serious temporal difficulties at home. The Romans broke out into rebellion, set up a republic, and deposed all the papal officers. The pope took refuge in the church of St. Chrysogonus, and some accounts even say that he was thrown into prison. He escaped to Ostia in disguise, and thence went to Florence, where his minister Vitelleschi, whose cruelties are said to have caused the revolt, quelled the insurrection, and punished the leaders with extreme severity. Beside the troubles which we have mentioned, Eugenius had to witness the devastations of the Turks, and was charged with being the indirect cause of the disasters which they inflicted upon the Hungarians and Poles. The legate cardinal Julian had counselled the Christians to break their truce with the Ottomans, but whether Eugenius was answerable for the advice is not agreed. The pontiff's character has engaged the attention of historians. He is praised for modesty, zeal, courage.

patronage of art, and many personal virtues, and is accused on the other hand of inordinate ambition and haughtiness of spirit.

EULENSTEIN, KARL, an eminent performer on the Jews-harp, born in Heilbronn, Würtemberg, in 1802. While a child he showed a decided taste for music, and at 6 years of age constructed a violin, on which he soon gained a tolerable degree of skill. At 12 he was apprenticed to an ironmonger, who, disliking music, refused to allow him to play upon any instrument, and took from him successively his violin, French horn, flageolet, and guitar. In despair Eulenstein resorted to the Jews-harp, an instrument he had been accustomed to sell at a penny each, and soon discovered that it was capable of a variety of tones and modulations of which he had never dreamed. He devoted 4 years of assiduous practice to the instrument, on which he acquired an astonishing skill, and succeeded in tuning a series of harps, whereby he could command a large scale, and modulate with truth and accuracy in every variety of key. For several years he passed a nomadic life of great privation as a performer on the Jews-harp in various parts of Germany, and finally settled in Stuttgart, where he played before the queen of Würtemberg, who gave him letters to influential persons. In 1825 he arrived in London, and excited much attention by his performances. Soon after his teeth became so much decayed by the action of the iron tongue of the harp that he was obliged to give up playing and devote himself to teaching the guitar. Subsequently a covering was made for his teeth by a dentist, by which he has been enabled to resume his performances on the Jews-harp.

EULER, LEONHARD, a Swiss mathematician, born in Basel, April 15, 1707, died in St. Petersburg, Sept. 7, 1783. He studied first under his father, a Protestant clergyman, and afterward at the university of Basel, where he formed a friendship with 2 of the Bernouillis, 3 of which family were officers of the university. Euler's genius was soon diverted from the church, for which he was intended, to philosophical pursuits. At the age of 19 he was graduated, after having already attracted the notice of the French academy of sciences by a memoir upon some points of naval architecture. In the following year, being disappointed in his wish for employment at the university, he repaired to St. Petersburg, where, his friends the Bernouillis having professorships, he had hopes of the patronage of the empress Catharine I. She died before his arrival, and Euler became so straitened in circumstances as to have been on the point of enlisting in the Russian navy as a common sailor. This step was fortunately prevented through the friendship of Daniel Bernouilli, who at length obtained for him the professorship of natural philosophy. In 1733, on the retirement of this friend from the academy of St. Petersburg, Euler became professor of mathematics. He labored in his new calling with indefatigable industry, and exhibited the

most astonishing powers of mind. In 1740 he gained the prize of the Paris academy, for an investigation of the nature of tides. Meanwhile his publications on the nature and propagation of sound, on curves, on the integral calculus, the movement of celestial bodies, &c., had already gained him wide reputation. In 1741, at the invitation of Frederic the Great, he left St. Petersburg for Berlin. The despotism of the Russian government had never perhaps been agreeable to a man of such liberal principles; and it is said to have added to his habits of silent thought and study. His reserve attracted the observation of the Prussian queen dowager, who inquired into its cause. "Madam," Euler is said to have replied, "I have been living 13 years in a country where men who speak are hanged." He remained at Berlin 25 years, until 1766, during which period he lost his mother, who had lived with him. His wife, whom he had married in St. Petersburg, was the daughter of a Swiss artist named Gsell. Many years later, in 1776, her aunt became his second wife. His children numbered 13, only 4 of whom survived him; the eldest son being his assistant and successor at St. Petersburg, and the second physician to the empress Catharine II. During Euler's residence at Berlin, he continued to hold his Russian appointments, and even drew a portion of their salary, receiving at the same time from all parts of Europe the most flattering marks of respect. When the dominions of Frederic were invaded by a Russian army in 1760, and a farm belonging to Euler was laid waste, the empress Elizabeth immediately reimbursed his losses. These generous acts, among other motives, induced him to accept an invitation from the empress Catharine II. to return to St. Petersburg in 1766. He had during some years previously suffered from weakness of the eyes; and soon after returning to Russia, he became so nearly blind as to be able only to distinguish very large chalk marks on a blackboard. The affection was the consequence of fever brought on by a calculation, for which his fellow academicians demanded 4 months, but which Euler completed in 8 days. He continued almost blind during the remainder of his life; but by constant exercise he acquired a power of recollection of mathematical formulæ and figures almost incredible. He is stated to have formed in his head and retained in his memory a table of the first 6 powers of numbers up to 100 (about 8,000 figures). Two of his pupils, it is added, had summed 17 terms of a converging series, and differed by a unit in the 50th decimal in the result. Euler decided the point correctly by a mental calculation. Some of his most profound and valuable works were composed after his loss of sight; among them, his "Elements of Algebra," and "New Theory of the Motions of the Moon." His studies were never relaxed, until cut off by his sudden death while conversing with a pupil on Herschel's planetary discoveries. In more than 50 years of incessant labor, Euler had composed 80 sep-

arate works, and more than 700 memoirs or treatises. The whole could not be contained in less than 40 large 4to. volumes. They embrace every existing branch of mathematics, and almost every conceivable application of them. They are all the original fruit of his own brain. To Euler belongs the credit of improving the analytic method, according to the system of Leibnitz and the Bernouillis, and of uniformly applying it to scientific investigations. Nor was he less remarkable for his popular expositions of the principles of his favorite science. His "Letters to a German Princess," which have been translated into English, and several times reprinted, throw a clear light on the most important facts in mechanics, optics, acoustics, and physical astronomy, and, though to some degree superseded by the progress of modern discovery, will always remain a model of perspicuous statement and felicitous illustration. His "Introduction to Algebra," translated by Prof. Farrar of Harvard college as preliminary to the Cambridge course of mathematics, has never been surpassed for its lucid and attractive mode of presenting the elements of that science. Euler was a man of simple, reserved, and benevolent mind; with a strong devotional sense and religious habit. He undertook to prove the immateriality of the soul, and had the courage to defend revelation at the court of a free thinker like Frederic II. of Prussia.

EUMENIDES, called also Erinnyes, and by the Romans Furie and Diræ, the avenging goddesses of the Greek mythology, daughters of night, and tormentors of the wicked both in the upper and the lower world. The Greeks dreaded to call them by an appropriate name, and therefore addressed them euphemistically as the Eumenides, or soothed and gentle goddesses. They seem to have been originally a personification of the curses pronounced upon a criminal, and are represented by Homer as resting in the depths of Tartarus till the condemnation of some person for violated pious or hospitable duties wakes them into life and activity. They then pursue the offender with the relentlessness of fate, chasing him from place to place, allowing him no peace nor rest, moved by no supplications, and supported by the goddess of justice, whose ministers they are. As described by Æschylus, snakes instead of hair enveloped their heads, their eyes were bloody, their faces black and full of hatefulness, and they bore torches and daggers in their fleshless hands. In the later poets wings were added, and their number was reduced from an indefinite number to 3, bearing the names of Tisiphone, Alecto, and Megæra. The terrific drama of Æschylus entitled "Eumenides" is said to have frightened several Athenian matrons into premature labor, and in subsequent representations upon the stage and in art their appearance was greatly softened down.

EUNAPIUS, a Greek sophist, physician, and biographer, born in Sardis, in Lydia, A. D. 347, died about 420. He was an adversary of Christianity, and an enthusiastic partisan of the em-

peror Julian. At the age of 16 years he went to Athens, where, after 4 years' study, he was admitted to know the secrets of the theurgic doctrine of Iamblichus, and was initiated into the Eleusinian mysteries. He returned to Sardis as a teacher of rhetoric, and studied medicine. There remains from him a book entitled "Lives of the Sophists and Philosophers," which gives the history not only of the philosophers, but of the physicians and rhetoricians, and of nearly all those who became known in science and letters from the beginning of the 3d to the end of the 4th century. The best edition is that of Boissonade (2 vols. 8vo., Amsterdam, 1822).

EUNOMIUS, a heresiarch of the 4th century, a native of Dacora in Cappadocia, who studied theology under the Arian teacher Aëtius, and was made bishop of Cyzicus about A. D. 360. His opinions were a logical exaggeration of Arianism. He was soon deposed from his bishopric, resided at Constantinople during the reigns of Julian and Jovian, and at Chalcedon during that of Valens; was banished by the last named, but soon recalled; was again banished by Theodosius the Great to Halmyris in Mœsia, driven thence to Cæsarea, and at length permitted to return to his native village, where he spent the remainder of his life, and died at an advanced age. His works were ordered by imperial edicts to be destroyed, but there remain of them a "Confession of Faith," which was presented to the emperor Theodosius at Constantinople in 383, and an "Apologetic Discourse," a famous treatise, of which St. Basil wrote a refutation in 5 books. His disciples were called Eunomians and also Anomœans (Gr. *ανωμοιαι*, dissimilar), because, unlike the Arians or Homoiousians and the Athanasians or Homoousians, they affirmed that the Son and Holy Spirit were neither identical nor similar in essence with the Father. They acknowledged the Father as supreme, eternal, and distinct; the Son as generated from the Father, and the Holy Spirit as generated from the Son. Like their founder they were accustomed to subtle speculations upon the divine nature, the incomprehensibility of which they denied. They rejected mysteries, and opposed the honors rendered to martyrs and to the relics of saints.

EUNUCHS (Gr. *ευνουχος*, from *ευνη*, a bed, and *εχω*, to guard), emasculated men employed in the East from time immemorial to take charge of women. According to Ammianus, the practice of castration was originated by the cruel ingenuity of Queen Semiramia. A product of oriental polygamy, jealousy, and despotism, eunuchs were early common in Egypt, Syria, Asia Minor, and the neighboring countries, were introduced thence into Greece and Rome, among the later Romans were admitted into the families of senators and emperors, and by their skill in flattery and intrigue often established their power at court, especially under the Byzantine empire. The Romans ingeniously devised a method of making castration more

or less complete. Gibbon affirms that the general history of Persia, India, and China proves that the power of the eunuchs has uniformly marked the decline and fall of every dynasty. They are still employed in the East as guardians of the harem, black slaves from Ethiopia being generally preferred. The example of Origen and the sect of the Valesians mark their appearance in church history and discipline. With some exceptions, they have exhibited an ungenial, suspicious, supple, and treacherous character. In Rome they were not permitted by law to appear as witnesses, and in modern times the *castrati*, famous as singers for the peculiar quality and clearness of their voice, are excluded by the Catholic church from the office of the priesthood. The custom of castration for the purpose of improving the voice came into use in the middle ages, chiefly in Italy, where, in the 18th century, it was estimated that 4,000 boys annually suffered in order to become singers in operas, at concerts, and in the celebration of the mass. The operation checks the growth of the beard, and gives a feminine character to the physiognomy and general physical development, though when performed in early youth it tends to increase the stature of the man. The eunuchs of the Turkish harems are mostly made so in upper Egypt, near Nubia, at a village where the operation of castration is performed by Coptic priests. It is stated that about 1 in 7 of the boys die in consequence of the operation.

EUPATORIA (formerly *Koslor*), a seaport town in the Russian government of Taurida, on the W. coast of the Crimea, and the capital of the district of the same name, situate on the N. shore of the bay of Kalamita, in about lat $45^{\circ} 14'$ N., long. $33^{\circ} 25'$ E., about 40 m. from Simferopol, and 44 m. from Sebastopol. Under the Tartars it was one of the most prosperous and populous towns in the Crimea. Before the Russian occupation of the Crimea, when the name of Eupatoria was given to the town by Catharine II., it had a population of above 30,000. According to the census of 1851, it had only 8,200, but it is now (1859) estimated at 14,000, chiefly Tartars and Caraites Jews. It has a considerable trade in grain, and some trade in hides, butter, wax, &c. The export of salt, which is drawn from adjoining salt lakes, and from which the Tartars formerly derived great profit, has fallen off considerably since the increase of the export duties. Butter, felt stuffs, and the black lambskins known in England as Astrakhans, are prepared in the town. The port is shallow, but safe, and never frozen up. To supply the town with water an Artesian well has been dug by order of the Russian government, 460 feet deep, and furnishing a daily supply of 120,000 gallons. The principal buildings are a Russo-Greek church, an Armenian church, 2 synagogues, and about 18 mosques, the chief of which, built by Devlet-Ghiri Khan in 1552, is the finest in the Crimea. On Sept. 14, 1854, the English and French effect-

ed a landing in the bay of Eupatoria, with about 60,000 men. The town was provided with fortifications by order of Omar Pasha, who was at the head of the Turkish army there, in 1855. The Russians made an ineffectual attack on the town, Feb. 17, 1855. It was evacuated by the allies after the ratification of the peace of Paris, May 30, 1856.

EUPHRATES (Turk. *El Frat*), called also by the natives of the country through which it flows the Murad, the largest river of western Asia, has its source in the mountains of Armenia, N. E. from Erzroum, where it is formed by the junction of 2 rivers, the Kara-Soo and the Murad, near Kebban, in lat. 39° N. and long. $38^{\circ} 30'$ E. It flows S. W. past Samosta, where a chain of high mountains prevents its further progress toward the Mediterranean. It then turns its course to the S. E., traverses a wild defile of Mount Taurus, separates Anatolia from Turkish Armenia, keeps its way without deviation till near its junction with the Tigris, and the united rivers fall, under the name Shat-el-Arab, into the Persian gulf. Its total length is nearly 1,800 m., its average breadth about 200 yards, and its depth from 12 to 30 feet. The upper part of its course lies amid lofty mountains, and near the village of Pash-tash it plunges through a gorge formed by precipices more than 1,000 feet in height, and so narrow that it is bridged at the top. It then enters the plains of ancient Babylonia, where the swiftness of its current is diminished, and where in ancient times numerous canals extended from its banks to irrigate the neighboring country. It extricates itself from the marshes of Lemlool just before reaching Korna, the point of its union with the Tigris. It is navigable both below and above the cataracts which it forms in the passes of the Taurus, though numerous islands, shallows, and rapids make its navigation in many places difficult. Its waters are subject to periodical increase from the melting of the snow on the mountains along the upper part of its course, and its inundations were anciently of great advantage to the agriculture of the level districts through which it passes. Under the misrule of the Turks, however, the canals and embankments which regulated the inundations have been neglected. The Euphrates is linked with the most important events in ancient history. It is mentioned in the Bible as one of the 4 rivers of paradise, and is often named the great river. On its banks Nimrod is said to have founded the city of Babylon, which was for ages the seat of a great empire; and at Cunaxa terminated the ill-starred expedition of Cyrus the Younger, and began the famous retreat of the 10,000 Greeks under Xenophon. It was for a long time the eastern boundary of the Roman empire. In recent times the English have tried, thus far unsuccessfully, to use it as their path of communication with India. For this purpose an expedition was sent from England under command of Col. Chesney, which in 1856 descended

the river from Bir and surveyed 509 miles of its course. (See CHESNEY.) It is a singular fact concerning the Euphrates that several thousand years ago the waters do not seem to have reached the sea at all, but were lost in marshes or consumed by irrigation, which was practised on an immense scale under the Babylonian and Assyrian sovereigns. It is certain that at a much later period the Tigris and Euphrates flowed into the sea by distinct channels. Their junction is supposed to have taken place more than 2,000 years ago.

EUPHUISM (Gr. *εὐφύης*, elegant), an affected style of speech which distinguished the conversation and writings of many of the wits at the court of Queen Elizabeth. The name and the style were derived from the "Euphues, the Anatomy of Wit" (1580), and the "Euphues and his England" (1581), of John Lilly, of which Anthony à Wood said: "Our nation is indebted for a new English in them, which the flower of the youth thereof learned." The style of these once famed books, which became the model of the wits and gallants of the time, and was almost regarded as a test of courtly breeding, was characterized by smoothness and verbal elegance, and chiefly by fantastic similes and illustrations formed by attributing fanciful and fabulous properties to animals, vegetables, and minerals. Supported by fashionable sanction, Lilly was for a time esteemed the rival of Demosthenes and Cicero in "all the partes of rhetoricke, in fitte phrases, in pithy sentences, in gallant tropes, in flowing speech." But the applause was not universal. Euphuism is ridiculed in Marston's comedy of "What You Will," in Ben Jonson's "Cynthia's Revels," and is thought to be referred to in the style of Don Armado in Shakespeare's "Love's Labor's Lost," and Sir Walter Scott in his "Monastery" makes Sir Piercie Shafton "parley euphuism."

EUPOLIS, one of the 6 Greek comic poets whom the grammarians of the school of Alexandria judged worthy of a place in their canon, born about 446, died about 411 B. C. He belonged to the old comedy, was a disciple of Cratinus, and composed 17 pieces, 7 of which were crowned. He was reputed superior to Aristophanes in elegance, and in bitter and personal jests was the rival of Cratinus. Among the objects of his satire were Alcibiades and Socrates, the former of whom, according to one report, exasperated by his attacks, threw him into the sea, where he was drowned. He is also said, with more probability, to have been killed in battle during the Peloponnesian war. The fragments of his plays have been edited by Runkel (Leipsic, 1829), and are contained in Meineke's *Fragmenta Poetarum Comicorum Græcorum* (Berlin, 1839-'47).

EURE, a N. department of France, formed in 1790 by the union of 4 ancient districts of Normandy, bounded N. by the mouth of the Seine and the department of Seine-Inférieure, E. by Oise and Seine-et-Oise, S. by Eure-et-Loir and

Orne, W. by Calvados; area, 2,248 sq. m.: pop. in 1856, 404,665. It has a level surface, naturally divided into 6 plateaus by the rivers Eure, Andelle, Eure, Iton, Rille, and Charentonne, which flow through it to the Seine; and it presents well cultivated fields and enclosures, fine forests, marshes, and a few hills. Agriculture is carried to a high degree of perfection, and the vine, apple, and pear are objects of special cultivation. Its most celebrated and flourishing cloth manufactories are at Louviers. It has important copper founderies at Romilly, and manufactories of nails, pins, &c. It has considerable commerce, chiefly in its own manufactured and agricultural products. It is divided into 5 arrondissements, and forms the diocese of Evreux, which is its capital city.

EURE-ET-LOIR, a N. department of France, formed in 1790 of parts of the ancient provinces of Orléanais, Ile-de-France, and Maine, bounded by the departments of Eure, Seine-et-Oise, Loiret, Loir-et-Cher, Sarthe, and Orne, and comprised in the basins of the Seine and the Loire; area, 2,117 sq. m.; pop. in 1856, 291,074. Its general aspect is that of a plain, with slight undulations of hill and valley, and its soil is unsurpassed in fertility by any in France. Its climate is mild, with frequent rains in spring and autumn. There are but small remains of the immense forests which formerly covered its surface. Cereals, the vine, prune, pear, cherry, and apricot are cultivated. It has some cloth manufactories. It forms the diocese of Chartres, which is its capital city.

EURIPIDES, the last of the illustrious trio of the tragic poets of Athens, born, according to the almost unanimous consent of the ancient authorities, in the island of Salamis, in the 1st year of the 75th Olympiad, 480 B. C., and, as was generally believed, on the very day of the battle of Salamis (Sept. 23). The Parian marble alone carries back the date of his birth to 483, or the 3d year of the 78d Olympiad. He died in 406. The name Euripides is said to have been bestowed upon him in commemoration of the battle of Artemisium, fought not long before, near the channel of the Euripus. He was the son of an Athenian citizen named Mnesarchus, and his wife Clito, of the deme of Phlya and the tribe Cecropia, or according to others of the deme of Phyle and the tribe Ceneis. His parents had left Athens on the approach of Xerxes and his Persian host, and taken refuge in the neighboring island. The condition of the family was respectable and perhaps affluent, though Aristophanes, in his comic attacks upon the poet, describes his mother as a seller of herbs; but the weight of ancient testimony contradicts these assertions and insinuations of the great comic poet. The father of the future tragedian probably returned to Athens after the Persians were driven from the country. At all events, the education of his son occupied much of his attention. There was a legend that, induced by an oracle which declared that the youth was destined to be victo-

rious in the "crown contests," he caused his son to be trained in athletic exercises. While yet a boy, he is said to have gained the victory in the Eleusinian and Thesean contests; and at the age of 17 he offered himself at the Olympic games, but was not received. For a time he devoted himself to the art of painting, and some of his performances are said to have been seen at Megara. His genius, however, ranged through all the studies that were then cultivated at Athens. He studied rhetoric under Prodicus, the author of the admirable apologue of the "Choice of Hercules," who visited Athens as ambassador of his native city; physics under Anaxagoras, whose opinions gave a coloring to his poetry; and perhaps philosophy under Protagoras. He became an intimate friend of Socrates, who was 12 years his junior. At length, after trying his hand on other pursuits, the natural turn of his genius for tragedy manifested itself. His first piece was written at the age of 18, but there is no evidence that it was brought upon the stage. The *Peliades*, the first of his plays represented in his own name, was brought out in 455. This is not preserved. Fourteen years later, 441, he gained for the first time the first tragic prize. Ten years after this, in 431, he gained the first prize with the tetralogy, including the *Medea*, *Philoctetes*, *Dictys*, and *Theristæ*. In 428 he brought out the *Hippolytus*; in 412 the *Andromeda*; and in 408 the *Orestes*. He appears to have carried off the prize but seldom, if we consider the number of his plays—15 times according to Thomas Magister, or 5 times as others state—while he is said by some to have written 92, and by others 75 pieces, including the satyric dramas or afterpieces, with which the tragic trilogy was usually followed. Soon after the representation of the *Orestes*, Euripides appears to have accepted the invitation of Archelaus, king of Macedonia, to take up his residence at that court. He had already held possession of the Athenian stage for more than 50 years, and had written an extraordinary number of masterpieces in the art to which his life had been devoted, when he left the city which his genius had adorned, to try the hazardous and uncertain experiment of residence at a foreign court; but there were some powerful reasons which urged him to this step. The rivalries in his art, and still more the attacks to which he exposed himself by the freedom of his philosophical and religious opinions, probably embittered his life at Athens. According to tradition, Euripides was not happy in his domestic relations, but the details on this subject seem to rest on no credible authority. He was married to Choerilla, the daughter of Mnesilochus, and by her had 3 sons, Mnesilochus, Mnesarchides, and Euripides. There are strong reasons for disbelieving the statement that he divorced his wife for infidelity; and that the second proving equally bad, he withdrew in disgust to the court of Macedonia; or that he withdrew in consequence of having detected an

intrigue between Choerilla and an actor named Mnesilochus. He lived but a short time after he went to Macedonia. According to tradition, he was torn in pieces by the hounds of the king. During his short residence in Macedonia, he acquired a great ascendancy over the king, who loaded him with gifts and honors. When the news of his death reached Athens, it threw the whole city into mourning. Sophocles, then 90 years of age, was so deeply moved that he changed his garments, and required his actors to lay aside their crowns and appear in mourning on the stage. The Athenians requested that his remains might be sent home for burial; but the request was not granted. The Athenians, however, erected a cenotaph to the poet, on the road from the Piræus to Athens, and his statue was afterward set up, with those of Æschylus and Sophocles, in the Dionysiac theatre, by Lycurgus the orator, a contemporary of Demosthenes. The beautiful inscription on the cenotaph is supposed to have been written by Thucydides the historian.—Of the numerous works of Euripides only 19 entire pieces have come down to our times. Many fragments of other plays exist, and are published in the editions of his works. Of the extant pieces, the genuineness of one, the *Rhesus*, has been called in question. Seventeen are tragedies, and two, the *Cyclops* and the *Alcestis*, were intended as afterpieces, like the satyric dramas (of which the *Cyclops* is indeed the only remaining specimen) in tetralogies. The earliest of all is the *Alcestis*, which was brought out in 438; the date of the *Orestes* is the latest ascertained, 408; but several of his pieces were brought out after the poet's death by his son Euripides. The best editions of Euripides are those of Beck (Leipsic, 1778-'88), of Matthiæ (Leipsic, 1813-'29), and the Glasgow edition in 1821. The edition of Paley, now passing through the press in London—two volumes of which have already appeared—will certainly be the most beautiful, and probably the most useful. The whole works of Euripides have been translated into English verse by Potter (2 vols. 4to., London, 1781-'4; 2 vols. 8vo., Oxford, 1814), and into prose by Buckley in Bohn's "Classical Library."—On the moral, intellectual, and poetical merits of Euripides there was in ancient times, as there is in modern, a great diversity of opinion. Among his contemporaries, Socrates thought so highly of him that he made it a point to attend the theatre whenever a play of his was to be performed, and the philosopher delighted in his conversation. Aristophanes, on the other hand, pursued him with the keenest and most unrelenting ridicule, denouncing him as the corrupter of tragedy and the teacher of immoral doctrines, and contrasting him unfavorably in these respects with Æschylus and Sophocles. In modern times, A. W. Schlegel and the critics of his school have adopted the representations of Aristophanes as the basis of a serious but most disparaging judgment. The objections made to him have some foundation, but they have been

pressed altogether too far. Aristotle, with his calm, impartial, and judicial criticism, while censuring his faulty management in some respects, yet pronounces him the most tragic of poets; and this, too, with the works of Sophocles and Æschylus before him. Milton's opinion nearly coincided with that of Aristotle. Euripides is censured as a woman-hater, and it is supposed that his distrust of the female sex grew out of his own domestic experience. He, like Socrates, is charged with a want of belief in the gods of his country. That might be an objection to some among his contemporaries, and perhaps it made the handling of mythological personages cold and unnatural on some occasions; but it ought to have little effect on modern judgment. In a literary point of view, the principal charges against him are that he lowered the tone of tragedy and weakened its style; that he degraded heroic characters, by representing them in beggary and rags, and by these coarse means attempting to work out pathetic effects; that he too often introduced his plays with long and tedious narrative or genealogical prologues; that his choruses frequently have little to do with the subject of the piece; and finally, that he delighted in the representation of criminal and unnatural passions. These statements, though having a germ of fact, are quite too absolutely made. His predecessors, Æschylus and Sophocles, had moulded the Attic dialect to forms of eloquence and grandeur, suitable to express the lofty sentiments of the great heroic characters they delighted to portray. The genius of Æschylus was naturally grave and elevated; his education and his experience of life had confirmed the original tendencies of his mind. He had shared fully in the great excitements and the sublime heroism of the Marathonian times. He had fought with distinguished bravery, both at Marathon and at Salamis. He was a Pythagorean, and had been initiated into the Eleusinian mysteries. His style of thought and expression was moulded by all these influences, and both had a solemn religious character. His ideas of the divine nature, of sin, of retribution, rise into the highest region of ethical and religious speculation; and his lines, whether in chorus or iambic, breathe a spirit in entire accordance with the loftiness of his conceptions. In his style Euripides is not lofty like Æschylus, nor elaborately elegant like Sophocles. In his plots he is not so simple as Æschylus, nor so carefully balanced as Sophocles. But in the study of human passions, in the analysis of the characters of men and women, in tracing actions to their hidden motives, through all the labyrinthine windings of pretence or self-deception, he is undoubtedly their superior. In his plays there is more of philosophy, in spite of the occasional sophistry that deforms them; there are more pithy maxims, sententious expressions of metaphysical and ethical truth, and discussions that really evolve important conclusions bearing upon the conduct of private or public

life. If we judge by the busts and statues of Euripides that have come down to us in the collections of ancient art, he was a man of capacious brain, of grave if not melancholy countenance, and studious habits; and these impressions correspond to those made by a careful study of his works. In the freedom and flow of his style, beside its general elegance, we are struck on every page with apparently unstudied felicities of expression, which only Shakespeare, of modern dramatists, has equalled. His feeling for nature is deep, and the language in which that feeling is always expressed is wonderfully beautiful. Few poets have ever equalled him in the truthfulness of his characters. We censure him for having taken from life so much that was mean and unworthy of being adorned by his genius. In the character of Admetus, for example, it must be said that his miserable fear of death, and the contemptible means he resorted to to escape it, his shabby reproaches against his poor old father for refusing to die for him, make us regret his good fortune in possessing such a wife as Alcestis. If he was a woman-hater at times, he certainly knew how to do full justice to the nobleness, magnanimity, and disinterested affection of which woman is capable, as in that transcendently beautiful, but wholly natural and possible character. Where he seems to show an opposite tendency, by putting into the mouths of his characters sentiments disparaging to the purity and generosity of woman, these sentiments were doubtless drawn from what he had seen of the dark side of social life in Athens, and are by no means to be considered as the expression of a general misogynical judgment of the sex. Of the dramatic power exhibited in the character of Medea there can be but one opinion. This character is one of the most overwhelming power in dramatic literature, and is carried out with a vigor of conception, splendor of language, and unfailing consistency that mark only the very highest productions of genius. The character of Phædra has been censured as a presentation of unnatural passion. At the first glance there seems to be some truth in this censure; but we are confident that the critic who studies it faithfully will come to a different conclusion. She has fallen a victim to an irresistible power; and under that supernatural influence—not supernatural according to Greek conceptions—is led to crime, ruin, and death. It is a defecation of terrible beauty; how terrible, and how beautiful, no modern can wholly understand who has not witnessed the wonderful representation of it by Rachel. She professed to play the Phædre of Racine; but she rose from the words of Racine to the conception of Euripides. But we have not space to follow out this theme into further details. We will only add, that beside those we have already mentioned, Cicero and Quintilian of the ancients were among his warmest admirers; and the general estimation in which he was held is shown by the number of his pieces which have sur-

vived, being 5 more than those of Æschylus and Sophocles together. The attacks of Aristophanes, and the graver condemnation of Schlegel, must be taken with large abatements; and a just judgment, while it admits that he had serious faults, must place Euripides high in the first class of tragedians.

EURIPUS, the ancient name of the narrow straits separating Bœotia from the island of Eubœa, or Negropont, in the Grecian archipelago. Both ancients and moderns speak of the extraordinary irregularity and violence of ebb and flow in these straits, changing, as Livy remarks, suddenly like the wind, and not merely 7 times every day, as was believed. A bridge was built over them connecting Chalcis of Eubœa with the mainland. The modern name is Egripo, or Stretto di Negroponte.

EUROCLYDON, the Greek name of a very tempestuous wind (Acts xxvii. 14), now known as a Levanter. It is of the nature of a whirlwind; and its danger results from its suddenness, violence, and the uncertainty of its course.

EUROPA, in mythology, a daughter of Agenor, king of Phœnicia, and sister of Cadmus and Phoenix; or, according to Homer, the daughter of Phoenix. Her beauty was said to be due in part to a recipe which had been stolen from Juno and given to her. She gained the love of Jupiter, who effected her abduction by playing with her in a meadow in the form of a gentle white bull, and when she had mounted upon his back, he started with her across the sea, and bore her attended by troops of nereids and tritons to the shores of Crete. There she became the mother of Minos, Rhadamanthus, and Sarpedon, and subsequently married Asterion, king of Crete.

EUROPE, one of the five principal divisions of the globe, the smallest except Australia, but the most important in the history of civilization. Geographically considered, it is merely a N. W. peninsula of the Asiatic continent, but from the earliest times it has been distinguished as a separate division of the globe. Its name in the time of Herodotus was applied only to that portion of the continent stretching from Thrace to the Peloponnesus, opposite Asia Minor. Different opinions obtain in regard to the etymology of the name. The belief that it originated in the myth of Europa was discarded by Herodotus. Since then there have been many other theories, none of which has remained uncontested. Ancient writers derive the name from Eurus (south wind), or from *eupros* and *asia* (a Scythic word, quoted by the Greeks), the broad land, or from *eupros* and *ωψ*, the broad-looking (land). Modern scholars have sought for the origin of the name in the Semitic languages. Thus Bochart derives it from the Hebrew word *ereb* (west), while others hold that it is a corrupt form of the words *hazra appa* (white-faced).—But little was known by the ancient Greeks of that portion of the continent lying N. of the great Alpine mountain system. In fact, for them the 3 large

peninsulas stretching into the Mediterranean embraced nearly all Europe. In Strabo's time the German ocean and the Baltic were considered as the northern boundary of the continent. The existence of the Scandinavian peninsula and the Arctic ocean appears not to have been known to the Romans before the time of Pliny. Indeed, it was not till the political supremacy was wrested from the Latin by the German race that the geographical knowledge of Europe was perfected. Though much smaller in size than either Asia, Africa, or America, Europe has for many centuries exerted a greater influence upon the destiny of other portions of the globe than all the other divisions. McCulloch says: "It is to the world at large what Rome was to Italy or Athens to Greece—the favored land *unde humanitas, doctrina, religio, fruges, jura, leges ortæ atque in omnes terras distributæ putantur.*" But this assertion, as it stands, is obviously too general. For nearly 1,000 years subsequent to the downfall of the Roman empire, Europe slowly and laboriously struggled through barbarism at a time when the Mongolian race in eastern Asia had already attained a more perfect state of society and culture. It is only within the last 4 centuries that European civilization has matured so far as to be able to wield a controlling influence over distant regions and to stamp its seal upon their political state.—According to Ritter, Europe, with all islands belonging to it, has a superficies of 8,700,000 sq. m. and 20,780 m., of coast line, including 790 on the Caspian sea. The extreme points of the European continent are:

North:	Cape North,	lat. 71° 10' N.,	long. 26° 00' 23" E.
South:	Cape Tarifa,	" 36° 00' N.,	" 5° 35' 37" E.
West:	Cape Roca,	" 42° 40' N.,	" 9° 30' 37" E.
East:	Sea of Kara,	" 69° 45' N.,	" 65° 20' 23" E.

The length of Europe from Cape St. Vincent in the S. W. to the sea of Kara in the N. E. is 3,430 m.; the width from Cape North to Cape Matapan (the southernmost point of the Greek peninsula), 2,420 m. Europe is bounded N. by the Arctic ocean and the White sea, E. by the Ural mountains and river and the Caspian sea, S. by the ridge of the Caucasus mountains, the Black sea, and the Mediterranean, and W. by the Atlantic and the German ocean. The boundary line between Europe and Asia is somewhat undetermined, but that which ascends the Ural river from its mouth at the Caspian sea to the Ural mountain range, and follows the crest of that range to the sea of Kara, is usually adopted. The islands of Nova Zembla are set down by Humboldt as properly belonging to Asia, since by their vertical configuration they appear as a continuation of the Ural range. Erman, on the contrary, shows their connection with the Scandinavian mountain system, and this is also the view taken by most English geographers. The continent proper has the shape of a rectangular triangle, the hypotenuse of which extends from the bay of Biscay to the sea of Kara, while the right angle rests on the Caspian sea. The area of this main

body of the continent is about 2,650,000 sq. m., that of the peninsular projections about 860,000, and that of the islands 195,500. Altogether Europe contains about $\frac{1}{3}$ part of the total area of the dry land of the globe. The proportion of the total area of the peninsular projections to the main body of the continent is as 1 to 3, a larger ratio than is found in any other division of the globe. A curved line drawn from a point in the Ural mountains, lat. 60° or 61° N., to the W. coast of Norway, lat. 69°, passing through Lake Onega and a little N. of the gulf of Bothnia, marks the extreme limits of cultivation. It cuts off an area of about 550,000 sq. m., or $\frac{1}{5}$ part of the entire surface. Europe is surrounded by water on 3 sides. On the N. the Arctic ocean, penetrating 450 m. into the continent, forms the White sea, which has an area of 85,000 sq. m. Its coast, situated for the greatest part within the temperate zone, has become a seat of culture notwithstanding its high latitude. On the W. the Atlantic ocean, narrowing between the British islands, the Scandinavian peninsula, and the continent, assumes the form of an inland sea (North sea, or German ocean, area 260,000 sq. m.), which is connected by the Skager Rack and Cattegat with the Baltic sea. The Baltic, comparatively a shallow sea, and less salt than the ocean, is almost entirely land-locked. By its numerous affluents, however, it has obtained a commercial and even a political importance in the history of the Germanic race, almost equal to that of the Black sea in early Greek history. Its area, exclusive of islands, is over 150,000 sq. m. The configuration of the southern coast of Europe is determined by the Mediterranean sea, a sheet of water 2,350 m. in length, covering an area of over 1,000,000 sq. m. By its position it forms the connecting link between Europe, Asia, and Africa, and for about 20 centuries the history of the Caucasian race was principally developed upon its coasts. The Black sea, connected with the Mediterranean by a narrow strait, is 700 m. long, 400 m. broad, and has a superficies of 180,000 sq. m. inclusive of the sea of Azof. The coast line along all these seas is 20,040 m., or one mile of coast line to 183 sq. m. of continent; 3,635 m. of coast line belong to the Arctic ocean, 8,480 to the Atlantic, and 7,925 to the Mediterranean. In consequence of the deep indentations of the sea, the western half of Europe contains no great inland country shut up from direct communication with the ocean. The distance from the bay of Biscay to the gulf of Lyons is only 257 m.; from the British channel to the same gulf, 469 m.; from the Pomeranian gulf to the gulf of Trieste, 584 m.; from the gulf of Dantzic to the Black sea, 782 m.; from the gulf of Finland to the sea of Azof, 1,012 m.; from the White sea to the sea of Azof, 1,255 m.; and from the sea of Kara to the Caspian sea, 1,656 m. Twelve large peninsulas are formed by indentations of the sea, 5 of them on the north, 8 on the west, and 4 on the south, viz.:

Names.	Area in sq. m.	Coast line in miles.
Kanin	8,500	434
Kola	34,900	694
Scandinavian peninsula.....	846,000	2,884
Jutland	12,600	350
North Holland.....	216	160
Normandy	864	65
Brittany	12,065	300
Iberian peninsula.....	229,000	1,280
Italian peninsula.....	61,900	1,610
Istria	700	115
Greece.....	142,000	2,200
Crimea	6,000	350
Total	630,035	12,121

Two of the 5 northern peninsulas stretch toward the Arctic ocean, and are consequently almost uninhabitable, viz., Kola and Kanin: the largest of the northern peninsulas (the Scandinavian) has a southern direction. Thus only a small portion of the coast configuration is lost to culture and commerce. The islands too, with the exception of Iceland, cluster so closely around the continent that, in considering the natural facilities which Europe offers to commercial intercourse, their coast line might be added to that of the continent. The principal of these islands are:

Names.	Area in sq. m.	Coast line.
Great Britain (main island).....	84,940	2,400
Ireland.....	82,702	1,360
Iceland.....	83,560	1,630
Danish islands.....	4,906	700
Corsica.....	8,877	220
Sardinia.....	9,336	220
Sicily.....	12,900	290
Candia.....	4,104	200
Total.....	190,512	5,430

Beside these, the following may be mentioned: Nova Zembla and Vaigats in the Frozen ocean; the Loffoden on the coast of Norway; the Aland archipelago, Öland, Gothland, Oesel, in the Baltic; Jersey, Guernsey, Alderney, &c. in the English channel; Ushant and Belkiah on the W. coast of France; the Azores in the Atlantic; Majorca, Minorca, Elba, the Lipari islands, Malta, the Dalmatian archipelago, the Ionian islands, the Sporades and Cyclades, in the Mediterranean sea.—Considered as a whole, Europe has an average elevation of only 660 feet above the level of the sea. The same direction from S. W. to N. E. which prevails in the coast configuration is perceptible in the position of the mountains and their different strata. All the peninsulas, those stretching to the northward excepted, are mountainous, as are the islands, while the plains cover the largest portion of the main body of the continent. The proportion of the plains to the mountainous regions in all Europe is as 5 to 2; but in that portion of Europe which has been preëminently the seat of civilization and the theatre of history, the mountains prevail over the plains as 3 to 1. A diagonal line of mountain ranges, extending from S. E. to N. W. (Caucasus, Carpathians, and Hercynian mountains), forms the dividing line between the mountainous and the

level portions of Europe. The latter, extending from the shores of the German ocean to the Ural, appear as a western continuation of the steppes of Siberia and Turan, intersected by the insular Ural range. While on the shores of the German ocean its width is only 98 m., this being the point where the mountain systems approach the ocean, in the extreme east it is 1,400 m. wide. Its entire length is near 2,300 m., its area 2,100,000 sq. m. Proceeding from the heaths of West Brabant in an easterly direction, even beyond the Ural passes to the steppes on the western slope of the Altai mountains, 80 degrees of longitude, no elevation of over 1,200 or 1,300 feet above the level of the sea is met with. The western or European portion of this plain appears to have formed, after the commencement of the tertiary period of geology, the bed of the sea. It includes the whole basin of the Baltic and White seas. A part of it is traversed by rivers flowing northward from the Alps, the Bohemian and Sudetic mountains. To the eastward the watershed between the Baltic and the Black and Caspian seas is only a few hundred feet in elevation; commencing at a spur of the Carpathians near the source of the Dniester, it runs through the Russian governments of Volhynia, Grodno, Minsk, Mohilev, Smolensk, Pskov, Tver, Novgorod, and Vologda, to the Ural range. Though interspersed with marshes, bogs, and heaths, this immense plain is susceptible of high culture, but nowhere is the soil so fertile as to produce crops without laborious diligence. Thus it became naturally the seat of a civilization based in part upon the sterling characteristics of the energetic Teutonic race. Connected with this large plain are two lesser ones, in France (94,000 sq. m.) and in Hungary (38,000 sq. m.).—The mountain system of southern and western Europe is grouped around the central mass of the Alps, which forms the summit and the principal watershed of the continent. The Alps, covering an area of 95,000 sq. m., slope down on 4 sides toward France, Germany, Hungary, and Italy. Although towering up in numerous steep and rocky summits, they constitute one of the most accessible mountain systems of the globe, and form by their extensive valleys and practicable passes rather a connecting link than a dividing line between the surrounding countries. The highest elevation of this system and of all Europe is Mont Blanc (15,782 feet, according to Bruguière). The lowest limit of perpetual snow in the Alps is 8,760 feet in the latitude of 45° N. Connected with the Alpine system are the mountain systems of the 3 southern peninsulas, viz., the Hesperic or Pyrenean system, the Apennines, and the Balkan, and also the group of the Carpathian and Sudetic mountains. The Pyrénées stretch from E. to W. for 240 m., but, including the Cantabrian mountains, their length is 500 m. Their S. side, toward Spain, is rugged and precipitous, while on the N. they descend gradually by a

series of parallel ridges into France. They send 4 principal chains through the Iberian peninsula, the whole system covering a superficial area of 210,000 sq. m. Their culminating point is the Cerro de Mulhacen in the Sierra Nevada (11,660 feet). The Apennines, stretching from the Alps through the entire length of Italy to the strait of Messina (840 m.), cover an area of 60,000 sq. m. Their highest summit is the Monte Corno (9,542 feet). The Carpathian and Sudetic mountains, with the Erzgebirge and the Böhmerwald, form one chain extending 1,200 m. in length, from the Danube in Hungary to the same river in Bavaria. Their highest elevations, from 5,000 to 8,000 feet, are in Transylvania and Hungary, where they surpass the lower limit of perpetual snow. The Balkan, a direct continuation of the Dinaric Alps, sweeps in an irregular curve from the Adriatic to the Black sea. It is the Mount Hæmus of the ancients. Its general elevation is about 4,000 feet, though the culminating point (Tchardagh) reaches the height of 9,700 feet. Thence one range, the ancient Pindus, diverges to the S., dividing Albania from Roumelia, and connecting with the mountains of Greece, the loftiest summits of which attain an elevation of 8,000 feet. Near the eastern end of the principal range the Little Balkan branches off in a S. E. direction, and, running parallel to the shore of the Black sea, terminates near the Bosphorus. Between the Alpine system proper, the Pyrénées, and the Atlantic (in France), there are 3 separate mountain ranges, viz., the Cévennes and mountains of Auvergne, the Jura, and the Vosges. The Cévennes divide the low country on the Mediterranean and the basin of the Rhone from the plains extending W. to the Atlantic; their general elevation is from 3,000 to 5,000 feet, though some peaks rise to a height of about 6,000 (Plomb de Cantal, 6,093; Mount Mezin, 5,918 feet). The Jura, of nearly the same elevation, extends along the frontier of France and Switzerland. Further to the N. the Vosges divide the basin of the Rhine from that of the Moselle, their summits ranging from 1,400 to 4,000 feet, and the loftiest only 4,693. There are several plains, independent and differing in their principal features from the great northern plain, enclosed by the Alpine system, to wit: the basin of the Po (15,000 sq. m.), the basins of the Rhone and of the upper Rhine (4,250 and 3,500 sq. m. respectively), and the Moravian plain (1,000 sq. m.). Beside the above mentioned ranges, all more or less immediately connected with the central system of the Alps, Europe contains, in its islands and peninsulas, 5 distinct mountain systems. They are the Sardo-Corsican, the Tauric, the British-Hibernian, the Scandinavian, and the Sarmatian. The Sardo-Corsican, as its designation implies, is the range of mountains stretching from N. to S. through the islands of Corsica and Sardinia; its highest summit, Monte Rotondo in Corsica, has an elevation of 9,054 feet. The Tauric system is con-

fined to the southern portion of the Crimea, its greatest elevation being 5,052 feet. The British-Hibernian system in Great Britain and Ireland is comparatively insignificant, rising in its highest peaks but little over 4,000 feet (Snowdon in Caernarvonshire, 3,570 feet; Cader Idris in Wales, 3,550; Ben Macdhu in Scotland, 4,390; Ben Nevis, 4,370; Cairntoul, 4,245; Helvellyn and Seafell in Cumberland, 3,055 and 3,166 respectively; Carran Tual in Ireland, 3,410). The Scandinavian Alps or Dovrefield extend 1,000 m. from N. to S. through the entire length of the Scandinavian peninsula, at a general elevation of from 3,000 to 6,000 feet. Their highest summits are the Sneehætten, 8,120 feet, and the Skagtöls Tind, 8,400. In the N. portion the lower limit of perpetual snow is at 3,500 feet above the level of the sea. The Sarmatian system consists only of a few scattered hill chains in Russia, Poland, and the N. E. part of Prussia; its greatest elevation, in the plateau of Valdai, is only 1,118 feet. The Ural range, which forms the N. E. boundary line of Europe, extends from N. to S. through 20 degrees of latitude, with a breadth of 40 m. and a general elevation of less than 2,000 feet, only a few summits rising to a height of 2,500 feet. Toward the S. it diverges into smaller ridges that extend to the Caspian sea, the sea of Aral, and the steppes of the Kirghiz. A volcanic belt extends through the southernmost portion of Europe from central Asia and Asia Minor through the archipelago, Greece, Naples, Sicily, Spain, and Portugal, to the Azores. Along this line destructive earthquakes are of frequent occurrence. Beside many extinct craters, there are two active volcanoes, Etna in Sicily and Vesuvius near Naples. In the north, Iceland constitutes a distinct volcanic region. Its principal volcano is Mount Hecla, some eruptions of which have lasted for 6 years. The S. W. portion of the island contains the famous geysers, or intermittent springs of steam and boiling water. There are two other volcanoes, one on the island of Jan Mayen, between Iceland and Spitzbergen, the other (mountain of Zarytcheff) on the northern island of Nova Zembla. Altogether Europe contains 37 summits of over 11,000 feet elevation above the level of the sea, 48 of more than 10,000 and less than 11,000 feet, 109 over 9,000 and under 10,000, 92 between 8,000 and 9,000, and 160 between 7,000 and 8,000. Of these, 320 belong to the Alpine system.—In accordance with the prominent features of the vertical elevation, 4 natural divisions may be pointed out in Europe: 1. Lower Europe, comprising Russia, Poland, Galicia, and the eastern provinces of Prussia. A monotonous plain, assuming the character of steppes in the S. and of swamps in the N., inhabited by the Slavic race under absolute monarchical rule, it forms the connecting link between Europe and Asia. 2. Upper Europe (Switzerland, Austria, Germany, Belgium, Holland, France) comprises the most diversified geographical formation, and is hence the seat of a varied social and political

development, which in Germany assumes almost the character of political dismemberment. In eastern portion, the basin of the Danube, shows some features of Asiatic geography, such as the puszta or prairies of Hungary. 3. Southern Europe consists of the three southern peninsulas (Spain and Portugal, Italy, Greece). Combining many of the advantages of the temperate and sub-tropical regions, it became the earliest recipient of Asiatic and African culture, to the influence of which a portion of it remained subject even at a time when Christian civilization had been vigorously developed by the Teutonic race in central Europe. 4. Northern Europe (the Scandinavian peninsula, Denmark, and Great Britain) is less favored in climate and natural resources, and hence most adapted to the development of energy, self-reliance, and daring courage.—The river systems of Europe are less extensive than those of either Asia or America. The principal watershed of the continent, running from S. W. to N. E., from the strait of Gibraltar to the sea of Kara, divides the continent into a S. E. and a N. W. slope, the former containing 57.5, the latter 42.5 per cent. of the total area (2,000,000 and 1,500,000 sq. m. respectively). On the S. E. slope the basin of the Caspian sea comprises about 500,000 sq. m.; that of the Black sea and the sea of Azof about 930,000 sq. m.; and the basin of the Mediterranean sea, 570,000, sq. m. On the N. W. slope the Atlantic basin and the basin of the Baltic comprise 460,000 sq. m. each, the basin of the German ocean 400,000, and that of the Arctic ocean 180,000. The following are the principal rivers flowing into the different seas: 1, Caspian sea: Ural and Volga; 2, sea of Azof: Don; 3, Black sea: Danube, Dniester, Dnieper. 4, Mediterranean: Maritza, Kara Soo, Vardar, Salembria, Aspropotamo, Arta (in Turkey and Greece), Drin, Narenta, Isonzo, Tagliamento, Piave, Brenta, Bacchiglione, Adige, Po, Rubica, Metauro, Ofanto, Sele, Volturno, Garigliano, Tiber, Ombrone, Arno, Var (Dalmatia and Italy), Rhone, Hérault, Aude, Tet, Tech, Ter. Llobregat, Ebro, Guadalquivir, Xucar, Segura (France and Spain); 5, Atlantic: Minho, Dura, Vouga, Mondego, Tagus, Caldas, Guadiana, Tinto, Guadalquivir, Guadalete; 6, bay of Biscay: Bidassoa, Adour, Garonne, Charente, Sèvre-Niortaise, Loire; 7, British channel: Orne, Seine, Somme; 8, German ocean: Scheldt, Rhine, Vecht, Ems, Weser, Elbe, Eider; 9, Cattegat: Götha Elf, Glommen; 10, Baltics: Ulea, Neva, Narova, Pernau, Düna, Windau, Niemen, Pregel, Passarge, Vistula, Leba, Lupon, Stolpe, Vipper, Persante, Rega, Oder, Rekenetz, Varnow, Trave, Motala Elf, Dal Elf, Angermann Elf, Umea Elf, Pitea Elf, Lulea Elf, and Tornea Elf; 11, Arctic ocean: Tana Elf, Onega, Dwina, Mezene, Petchora. Beside these, there are the rivers of the British islands, the chief of which are the Thames, Severn, Mersey, Trent, Ouse, Tyne, Tees, Wear, Mersey, Dee, Avon, Eden, and Derwent, in England; the Tweed, Clyde, Forth, Tay, Dee, Don, Spey.

Nith, and Annan, in Scotland; the Shannon, Brandon, Lee, Blackwater, Suir, Barron, Slaney, Liffey, Boyne, Baun, Foyle, in Ireland. The most important of these rivers are: the Volga, Don, Vistula, Danube, Oder, Elbe, Weser, Rhine, Rhone, Loire, Tagus, Thames, Severn, Mersey, Forth, Clyde, and Shannon. The largest river of Europe is the Volga, with a course of over 2,000 m. and a basin of over 500,000 sq. m.; next comes the Danube (length of course 1,770 m., basin 308,000 sq. m.). Artificial water courses connect the Caspian sea, the Baltic, and the Arctic ocean, by the Volga, Neva, and Dwina rivers; the Black sea and the German ocean by the Danube and Rhine; the Mediterranean and the Atlantic ocean, British channel and German ocean, by numerous canals between the Rhone, Garonne, Loire, Seine, Scheldt, and Rhine. The middle course of most of the large rivers is well adapted to navigation by steam and other vessels, but their usefulness for the purposes of commerce is restricted by obstructions at their mouths. Such is especially the case with the Volga, Don, Danube, and Rhine.—The lakes of Europe are small, and scarcely any of them important to commerce. The following are among the largest: Ladoga (6,330 sq. m.), Onega (3,280), Saima (1,600), and Enara (685), in Russia; Wener (2,135), Wetter (840), and Maelarn (760), in Sweden; lake of Geneva (240) and lake of Constance (200), in Switzerland; Garda (180) and Lago Maggiore (150), in Italy; and Lake Balaton (138), in Hungary. Four-fifths of the lakes in Europe are situated in the region around the Baltic sea.—The whole of Europe, with the exception of a small northernmost portion of the Scandinavian peninsula and Russia, being situate within the temperate zone, enjoys an equal and temperate climate, favorable to a healthy muscular development. The disadvantages arising from the proximity of the Arctic ocean and the climatic influences of northern Asia are more than overborne by many advantages which no other division of the globe enjoys in an equal degree. The prevailing winds are western, and hence before reaching Europe have been in contact with an expanse of water, the surface of which has, even in January and in lat. 45–50° N., rarely a lower temperature than 44°, 48°, or 50° F. In the second place, Europe is influenced by a broad tropical zone including Africa and Arabia, whose dry soil serves to warm the air carried to Europe by southern winds. On the other hand, the influence of the Arctic ocean upon the climate of the continent is neutralized by the Gulf stream. The combination of all these advantages explains the fact that the mean temperature of Europe is higher than that of any other division of the globe in corresponding latitudes, the isothermal lines of Asia and America bending in Europe to the northward by some 10 degrees of latitude. Thus in lat. 36° N. the mean temperature of the year is 66° F., and in lat. 71° N. (Cape North) it is 32° F., not lower than in

lat. 55° 56' N. on the E. coast of Asia and America. Owing to the causes before mentioned, the mean temperature of Europe is higher and the extremes are less in the same latitudes in the western than in the eastern part. The isothermal line of 50° F. (mean annual temperature) runs from London to Cracow and Odessa, that is to say, from lat. 51° 30' to 46° 22' N., thus declining nearly 5 degrees of latitude to the S. in a course of 31° 5' of longitude. The isothermal line of 59° F. runs from Bayonne, touching Ancona and Durazzo, to Larissa, or from lat. 43° 29' to 40° 16' N. in 24° 5' of longitude. A mean annual temperature of 68° is only met with on the southern coast of Portugal. But while the mean temperature diminishes advancing eastward, the extremes of the heat of summer and the cold of winter increase. Thus London has the same mean temperature as Vienna, which lies more than 3½ degrees further S., but it has the summer of St. Petersburg and the winter of Milan. The transitions from winter to summer and from summer to winter are less abrupt in the largest portion of Europe than they are in America. Almost everywhere the seasons succeed each other with great regularity. The extreme north only, where the winter lasts for 8 months, and the extreme south, form exceptions. The fall of rain is more equally distributed to the N. of the Alpine system than to the S. of it. It has been calculated that the entire quantity of rain falling in the N. part of Europe is less by ½ than in the S., but the snow of the N. covers the deficiency of rain. The western winds, being laden with the moisture which they have received in passing the Atlantic, generally bring rain, while the eastern winds are dry and chilly. From the same cause the average quantity of rain is largest in Great Britain, and decreases in advancing to the E. and S. E. Thunderstorms occur in the N. part of Europe almost exclusively during the summer, in the S. part at all seasons of the year.—The vegetation of Europe, dependent upon and corresponding to its climate, has not the extremes of luxuriance or sterility belonging to other great continents. Culture has diversified it, and has domesticated many plants, natives of other countries. Thus the vine, olive, and mulberry have been introduced from Syria, the cotton plant from India, maize from America, the walnut and peach from Persia, the apricot from Armenia, the sugar cane and orange from China; while many of the indigenous plants, especially vegetables (as lettuce, cabbage, turnips), have been improved by culture to such a degree that their relationship with their wild types is scarcely evident. Europe may be divided into 3 vegetable zones, viz.: 1. The sub-arctic zone, characterized by the prevalence of the pine and birch and of cryptogamous plants. Of grain it produces only barley, and no fruit whatever. This zone comprises Iceland, the Färöe islands, the Scandinavian peninsula N. of lat. 64°, and Russia to the N. of lat. 62°. 2. The central zone, subdivided into the zone of the beech and oak, and that of the

chestnut and vine. The former includes Great Britain and Ireland, the Scandinavian peninsula S. of lat. 64° N., and the German and Sarmatian plain between lat. 62° and 48° . The latter comprises the valleys and plains between the mountain ranges of central Europe and the Sarmatian plain. In the former, rye and wheat are the principal grains; in the latter, wheat and maize. 3. The southern zone, or the region of perpetual verdure, and of the olive, comprising the 3 southern peninsulas and the southern coast country of France, distinguished by a great variety and luxuriance of sub-tropical vegetation. The sugar cane, cotton plant, banana, orange, citron, fig, pomegranate, and date grow in the southernmost belt of this region. The zones in which these fruits and plants grow follow the lines of equal summer heat, and hence run from S. W. to N. E., since the extremes of summer heat and winter cold increase advancing eastward, though the mean annual temperature decreases. Thus the cotton plant is cultivated on a small scale in the southernmost portion of Spain, from lat. 36° to 37° , to a greater extent in Sicily, and also in the S. E. angle of Italy, in Greece as high as lat. $41\frac{1}{2}^{\circ}$, and at Astrakhan in lat. 46° . The olive, which does not succeed on the W. coast of France in lat. 43° , grows as far as lat. $44-45^{\circ}$ in the S. E. provinces of France and in Italy. The fig and pomegranate, which accompany the olive in the west, are found in the Crimea as far N. as lat. 46° . The climate proper for the culture of maize terminates on the W. coast of France at lat. $45^{\circ} 30'$, on the Rhine at 49° , on the Elbe at $50-51^{\circ}$. Rice has nearly the same geographical range. The culture of the vine extends as far N. as lat. $47^{\circ} 30'$ on the Atlantic coast, $50^{\circ} 30'$ on the banks of the Rhine, 52° on the Oder river. In Russia it grows as far N. as lat. 52° , but it is not cultivated beyond 50° . Altogether the region adapted to the cultivation of the vine comprises about $\frac{3}{7}$ of Europe, that adapted to the culture of wheat $\frac{4}{5}$. The N. limit of the latter is lat. $57-58^{\circ}$ N., though it is raised in a few favored spots in Finland as far N. as lat. 60° and 61° . The hardier kinds of grain, rye, barley, and oats, are cultivated on the W. side of Norway as far as lat. $69^{\circ} 55' N.$, but on the E. side of the Scandinavian mountains they scarcely ripen at $67-68^{\circ}$, and still further E. in Russia they cannot be cultivated beyond lat. $60-62^{\circ}$. Peaches and apricots succeed in Russia as far N. as lat. 50° , melons at lat. 52° ; and plums and cherries, growing wild as far as lat. 55° , are carried beyond that limit by cultivation. Tobacco is extensively cultivated over the greater part of Europe, from Sicily to Sweden, as are flax and hemp, though they thrive best between lat. 45° and 60° .—Europe contains the various minerals, though in unequal proportions. It is abundantly supplied with iron, copper, lead, coal, and salt, but produces comparatively small quantities of gold and silver. Gold, though widely diffused, is only found in a few places (Carpathians, Ural mountains, and Scandinavian

Alps) in sufficient quantities to repay the expense of working it. Silver is mined in the Hartz, the Carpathians, Ural mountains, Scandinavian Alps, and Sardinia. The richest iron mines are in Sweden, which produces the best quality, in Great Britain, which has the largest quantity, in Styria, Carinthia, Bavaria, the Pyrénées, the Carpathians, and the Hartz mountains. Copper is less abundant than iron: the richest mines of this metal are to be found in Hungary, the Saxon and Bohemian mountains, in England, the Ural mountains, and the Scandinavian Alps. Lead is wrought in most of the large mountain ranges, tin only in a few places (Cornwall and the Hartz). Mercury is likewise confined to a few spots, as the mines of Idria in Carniola, Deux Ponts in the Palatinate, and the Spanish province of La Mancha. The richest coal fields exist in the N. and W. parts of England, on both sides of the middle region of Scotland, in Ireland, Belgium, France ($\frac{1}{4}$ of the entire area of which country is stated to consist of coal beds), Germany, Catalonia in Spain, and Sardinia. Salt is either obtained by the evaporation of brine from salt springs, or from depositories of mineral salt, of which the most extensive are found within the Austrian empire at Wieliczka and Salzburg. Salt springs are numerous along the sides of all mountains belonging to the primitive formation. Large quantities of salt are also collected from the salt lakes of the Crimea. Zinc is wrought in England and Germany, and cobalt in Saxony. Beside these metals, antimony, bismuth, manganese, sulphur, alum, &c., are obtained in larger or smaller quantities in the different mountain chains.—The animal kingdom of Europe is far less varied than the flora. The diversities of the 3 zoological regions are inconsiderable, and the only real contrast is between the arctic animals of the extreme north, as the reindeer, white bear, &c., and the beasts of prey of the extreme south, the lynx, wild cat, &c. The original features of the fauna of Europe have been greatly modified by culture. Several species of wild animals have disappeared entirely in many countries, as the wolf and bear in Great Britain and in some parts of the continent, while others are becoming scarcer from year to year. Thus the jackal is now only found in Dalmatia, the urus and the elk in some Polish provinces of Russia, the porcupine in the extreme south, the monkey near Gibraltar, the chamois and ibex in the Alpine mountains. But if Europe is poor in wild beasts, it is rich in domestic animals. In the northernmost region, as far S. as lat. $65^{\circ} N.$ in Lapland, and lat. 63° in Russia, the reindeer abounds; central Europe has immense numbers of horses, horned cattle, sheep, goats, and hogs; and southern Europe possesses, beside these, mules, camels (the Arabian in Tuscany, the Bactrian in S. Russia), and buffaloes (in Spain). Altogether Europe has 150 species of mammals, 58 of which are peculiar to that continent. Of small birds Europe has 400 species, but many of them are only birds of passage. Among those

kinds of birds peculiar to certain regions are the flamingo, spoonbill, pelican, and vulture in the S., gray eagle in the N. eider duck (N. of lat. 55°), swan, and red grouse in the N. and N. E., bee-eater in the S. E., white owl in the extreme N., &c. Various species of turtles excepted, Europe has no large amphibia. Fish are more abundant on the N. than on the S. coast; herring and codfish are found only in the N., sturgeon in the Russian rivers and seas, anchovies and pilchards on the S. W. coast, tunny fish in the Mediterranean. Of insects, several kinds of tarantula and scorpions are peculiar to Europe. The silkworm is raised principally in the S. countries, the honey bee everywhere on the continent. The annelides of Europe include the medicinal leech (in Sweden, Germany, Hungary, and Poland). Europe is abundantly supplied with edible mollusks, but they are found in greater abundance and better quality in the Mediterranean sea than on the N. coast. Radiated animals, zoophytes, &c., also abound on the S. coasts, where some of them (the actinias) are used as food, and where the coral fisheries employ many persons. Generally the S. part of Europe possesses a greater variety of animals and species than the N., while the latter has them in greater numbers.—The inhabitants of Europe are a mixture of many different tribes, most of them belonging to the great Indo-Germanic stock of the Caucasian race. Of the aborigines of Europe nothing is known with any degree of certainty, although scientific researches have led to discoveries upon which the most singular theories have been based. Thus it has been attempted to prove that at one time, long before the dawn of recorded or even traditionary history, a negro race inhabited central Europe; and that after their extinction there was a period during which two races, distinguished by their cranial formation as long-heads and short-heads, inhabited the W. islands and the central part of the continent. Disregarding these theories, we find that in the W. of Europe the Iberians appear as the aboriginal inhabitants, of whom the Basques are believed to be the only extant remains. At a very early epoch these aborigines were intruded upon by people of the Gaelic or Celtic stock, who acquired possession of all France, Britain, Ireland, Spain, and the N. of Italy (Gallia Cisalpina). Afterward another kindred people, speaking a different language (the Cimbric, Cymric, or Cambrian race), conquered the N. of France, the S. and E. of Britain, and the N. W. shores of Germany. These 3 races, Iberians (Basques), Celts, and Cymri, are found in possession of the W. and S. W. of Europe at the dawn of history. In the E. and N. W. the Ugrian (Mongolian) races (perhaps the Scythians of the ancients), of whom the Lapps, Finns, Samoyeds, and the Magyars are the present remains, seem to have been the original inhabitants. At an early period the Sarmatians (Slavi) settled in the countries N. of the Black sea, and pressing N. E., gradually dispossessed the Ugrians of their coun-

try. Between the Ugrian and Sarmatian races of the E. and the Celts and Cymri of the W., the Germanic races are found at the earliest period of traditionary history pressing N. to conquer Scandinavia and S. against France and Italy. The S. E. of Europe was probably settled from Asia and Africa; history finds in Greece and Italy two races who afterward became known as the Hellenic and Roman. The former was the first to develop in Europe a high state of culture, which, having been received by the conquering Roman race, was carried over all the countries around the Mediterranean. Having exhausted their power, the Roman conquerors were in their turn overthrown by the hardy, vigorous, and barbarous northern nations, who, after having embraced Christianity, in the course of many centuries developed a new and different civilization upon the basis of the recognition of a common higher destiny of mankind. The Heruli, Ostrogoths, Longobards, and other Teutonic tribes, penetrated into and settled in Italy; Suevians, Visigoths, and Vandals in Spain; Franks and Burgundians in Gaul (France); Angles, Saxons, Jutes, and Frisians in Britain. In Italy, Spain, and France, the conquerors were mostly assimilated to the nations whom they had found there, and by their admixture with them the present so-called Latin or Romanic race was produced. In Britain, the invaders drove the original inhabitants into Wales, Cornwall, and Cumberland, but were in their turn invaded by Normans and French in the 11th century, when the admixture of all these different elements, Celtic, Anglo-Saxon, and Norman, gradually produced the present English race. In Spain, the Goths and Vandals were overrun by Arabs in the 8th century, and did not recover possession of the country for 7 centuries. In the S. E. the Hellenic race became during the middle ages largely mixed with the Slavic, while around the lower course of the Danube an intermixture of the ancient Dacians with a Roman colony produced the present Roumain or Wallachian race. Toward the end of the 9th century a Ugrian race settled in the ancient Pannonia, where they remain to the present day under the names of Magyars in Hungary and Szeklers in Transylvania. Of the Tartars who under Genghis Khan entered Europe in the 13th century, and kept possession of a large portion of Russia till the end of the 15th century, some descendants still remain in the S. of that empire. The Osmanli, another branch of the Mongolian race, invaded Europe in the 14th century, and have ever since kept possession of the S. E. corner of the continent. By mingling freely with W. nations they have lost many characteristic features of the Mongolian stock.—The population of Europe in 1850 was calculated at 266,000,000, or 74 to the sq. m., by Reden; at 267,000,000 by Bescherelle; at 296,000,000, or 88 to the sq. m., by Berghaus; while the "Encyclopædia Britannica" in 1855 sets it down at 258,678,856 only. Dieterici (1859) estimates it at 272,000,000.

Its distribution between the E. and W. portions is very unequal, the average population on a square mile being nearly 100 in the W. and only 80 in the E. With the exception of the 4 free cities in Germany, the canton of Geneva, and Malta, the greatest density of population prevails in Belgium (409); next come the kingdom of Saxony (353), England (332), the grand duchy of Hesse (266), the duchy of Saxe-Altenburg (263), the Netherlands (260), Great Britain (239), northern and central Germany (about 200), Ireland (203), Italy (199), the German provinces of Austria (180), France (176), Bavaria (154), Russia (30), Sweden (20), Norway (11), Iceland (0.15). The average natural increase per annum of the population varies from 0.5 to 1.2 per cent. It is 1.43 per cent. in Great Britain, 1.16 in Prussia, 0.6 in all Germany, 0.59 in France. Ireland is the only country in which there has been, of late, a decrease of population. There are in Europe altogether 39 cities with more than 100,000 inhabitants to each. Of the population of Europe more than $\frac{1}{2}$ belong to the Caucasian race, of which all, with the exception of 3,000,000 Jews and Arabs (Semitic stock), are of the Indo-European stock. The Indo-European nations all profess Christianity, and present in their historical progress so many features distinct from the Asiatic and African nations, that they may properly be termed the people of Europe. They are divided into 3 great branches, viz. : 1, the Romanic or Latin race (31 per cent. of the total population), inhabiting the mountainous S. W. countries on the Mediterranean and Atlantic ocean; they are sensitive, excitable, passionate, and vindictive, temperate in eating and drinking, imaginative and inventive; mostly Roman Catholics; 2, the Germans (28.2 per cent.), thronging the elevated plains and valleys of central Europe and the shores of the Baltic and Northern ocean; thoughtful, clear-minded, honest, industrious, persevering; mostly Protestants; 3, the Slavi (27.8 per cent.), thinly distributed on the plains of the east; less developed in intellectual qualities, of a temperament alternating between oriental languor and passionate excitement; Roman and Greek Catholics, representatives of the Asiatic principle in Europe. A connecting link between the Romanic and Teutonic races is found in the Belgians; between the Romanic and Slavic, in the Greeks and Wallachians; between the Slavic and Teutonic, in the East Prussians, Pomeranians, Lusatians, and Austrian Wends. Of the Mongolian race there are two principal branches, each of them numerous subdivided, viz., the Finns and the Turks. As a nation they stand on a still lower plane of intellectual and industrial development than the Slavic races; they are mostly Mohammedans or pagans. The Magyars, originally belonging to the same race, have been influenced so much by the Indo-European nations, that they scarcely preserve any of the features peculiar to the Mongolian family. The following table exhibits the different races which at this day inhabit Europe :

I. CAUCASIAN RACE.		
1. Indo-European nations.		
a. Romanic or Latin races.		
Greek (Pelagian) branch.....	2,300,000	
Italians	25,000,000	
Spaniards and Portuguese.....	19,000,000	
French.....	38,500,000	
Rhetians (Switzerland).....	200,000	
Wallachians	5,000,000	
		90,000,000
b. Celts.		
In Scotland and Ireland.....	6,000,000	
In Wales and Brittany.....	3,000,000	
		9,000,000
c. Germans.		
Germans proper.....	51,000,000	
Scandinavians:		
Danes.....	1,600,000	
Norwegians	1,400,000	
Swedes	3,500,000	
	6,500,000	
Anglo-Saxons.....	20,000,000	
		77,500,000
d. Slavi.		
Western Slavi:		
Wends	200,000	
Poles	10,000,000	
Cechs	4,800,000	
	15,000,000	
Eastern Slavi:		
Russians and Ruthenians.....	50,000,000	
Southern Slavi:		
Servians, Slovacks,		
Croatians, &c.....	7,500,000	
Bulgarians	4,000,000	
	11,500,000	
		70,500,000
e. Letts and Lithuanians.....		2,000,000
f. Basques and Euscaldunacs (ancient Iberians).....		700,000
g. Albanians and Illyrians.....		2,000,000
h. Armenians (in Transylvania and straggling settlements on the Don).....		300,000
i. Gypsies.....		200,000
		250,000,000
2. Semitic nations.		
a. Jews	3,000,000	
b. Maltese (Arabs mingled with Latins and Germans).....	100,000	
		3,100,000
		253,100,000
II. MONGOLIAN RACE.		
1. Finns.		
a. Baltic (Germanized) Finns (Livonians, Esthonians, Ingrees, Suonians, Carelians, Lapps)....		
	2,000,000	
b. Volgian Finns (Tchouvasha, Mordvinians, Tcheremisses, Teptiars).....		
	400,000	
c. Permian Finns, on the Kama, Dwina, and Petchora (Votjaks, Sirjünnes, Permlans)....		
	150,000	
d. Ugrian Finns (in Sweden and Norway)		
	50,000	
		2,600,000
2. Magyars (in Hungary and Transylvania).....		
	5,500,000	
3. Szeklers (in Transylvania).....		
	200,000	
4. Vogulians (Russ. province of Perm).....		
	60,000	
5. Samoyeds (in N. E. Russia).....		
	40,000	
6. Turks.		
a. Osmanli.....	2,400,000	
b. Nogai, Bassiana, Bashkirs, Meshtshereks, Tartars, over.....		
	100,000	
	2,500,000	
		10,000,000
Total		772,600,000

—Most of the languages spoken by the different nations of Europe show some traces of common though very remote origin. Modern linguistic science has proved their relationship with the Sanscrit, and its early correlative or derivative tongues, and groups them under the he-

of Indo-European, or Indo-Germanic languages. The following table exhibits all the European languages in their relations to each other:

I. Indo-Germanic languages.

1. Pelasgic group: *a*, ancient and modern Greek; *b*, Latin, from which, either by degeneration or by admixture with the Celtic, Germanic, and Slavic languages, the following have descended: Spanish, Portuguese, French, Italian, Rhaetian or Grison, and Wallachian; *c*, Albanian.
2. Germanic group: *a*, German (high and low Dutch) and English; *b*, Scandinavian (Icelandic, Swedish, Norwegian, and Danish).
3. Slavic group, divided into many dialects, as Russian, Illyrian, Servian, Bulgarian, Slovak, Bohemian, Sorbian (Wend), Polish.
4. Lettish group, divided into the Lett language proper, Lithuanian, and Samogitic.
5. Celtic group, formerly dominant in western and central Europe, but now only spoken in Ireland, Wales, and Brittany.
6. Aryan group, represented only by the language of the gypsies.

II. Finnish-Tartaric languages.

1. Finnish: *a*, Karelian; *b*, Esthonian, *c*, Livonian; *d*, Lappic.
2. Hungarian.
3. Turkish.

III. Basque, not related to any other European language, is spoken only in the north of Spain.

—With the exception of China proper, the physical culture of no other part of the world is so much developed as that of Europe. Of the total area 20 or 23 per cent. is non-productive, being either lakes, rivers, swamps, rocks, or occupied by buildings, or, like the extreme northern portion, unfit for human habitation; 86 per cent. is devoted to agriculture or cattle-raising; and over 40 per cent. is in forests, of which Russia alone has over 1,000,000 sq. m. The best cultivated countries are Great Britain, Germany, and France. The introduction of scientific methods of agriculture into these countries has tended steadily to increase the productive capacities of the soil. This is especially the case in Great Britain, where the average crop of grain to the acre is considerably larger than in the United States. The number of domestic animals in Europe is stated by Reden as follows: Horses 27,000,000, valued at \$775,470,000; horned cattle 80,000,000, value \$864,720,000; sheep 191,000,000, value \$687,600,000; asses 1,800,000, value \$12,600,000; goats 16,800,000, value \$36,450,000; hogs 87,500,000, value \$108,240,000; mules 800,000, value \$17,160,000; aggregate value of domestic animals \$2,502,210,000. The average yearly mineral production is, according to the same authority, of gold, \$26,000,000; of silver, \$8,024,000; of iron, 35,700,000 cwt., or \$128,876,000; of copper, 500,000 cwt., or \$11,520,000; of lead, 1,330,000 cwt., or \$4,795,200; of tin, 94,000 cwt., or \$2,635,200; of quicksilver, 23,400 cwt., or \$1,677,600; of coal, 536,500,000 cwt., or \$96,500,000; of brown coal, 10,000,000 cwt., or \$500,000; of salt, 53,300,000 cwt., or \$48,240,000; of brimstone, 22,500 cwt., or \$118,400; total, \$323,396,400. The industrial production is largest in Great Britain, Belgium, France, and Germany. The facilities of commerce have been increased extraordinarily within the last quarter of a century by turnpikes, canals, railroads, steamboats, ocean steamships,

&c. The total annual value of European commerce was estimated by Reden in 1853 at \$2,750,000,000 (\$1,400,000,000 imports, and \$1,850,000,000 exports). Of this amount the commerce of Great Britain represents over 30 per cent., Germany and Austria over 26 per cent. (viz.: the Hanse towns 12.46 per cent., the Zollverein 9.54, Austria 4), France over 14 per cent., Holland over 5 per cent., Russia over 4 per cent., Belgium over 3 per cent. Altogether over 66 per cent. of the aggregate value of European commerce falls to the share of the Germanic nations, while they number only 28.2 per cent. of the total population. The principal articles of food are the different kinds of grain, especially wheat and rye, though in some countries potatoes are to a large extent used as a substitute. The average annual quantity of breadstuffs consumed per head is: in Saxe-Altenburg, 10.92 bushels; in France and Würtemberg, 9.36; in Baden, 8.97; in Bavaria, 8.58–8.97; in England, 8.58; in Nassau, 7.8; in Prussia, Saxony, and Hesse, 6.24; in Luxemburg, 5.61. The annual consumption of meat exceeds 6,000,000,000 lbs.; the average per head is: in England, 80 lbs.; in Baden, 54; in Nassau, 52; in Bavaria and Würtemberg, 45; in Hesse-Cassel, 41; in France, Prussia, and Luxemburg, 40; in Saxe-Altenburg, 37; in Saxony, 36; in the grand duchy of Hesse, 35. The annual consumption of butter is near 5,000,000,000 lbs.; of cheese, over 2,000,000,000 lbs.; of milk, 22,500,000,000 gallons. The consumption of wine has for 10 years averaged 2,160,000,000 gallons; the annual average per head is: in France, 15 gallons; in the Palatinate, Würtemberg, Baden, and the grand duchy of Hesse, 6½–7½; in Rhenish Prussia, 3½–5; in Bavaria, 2½; in Nassau, 1½–2½; in Prussia and Saxony, ½; in England, 1.06 quarts. The average annual consumption of beer is: in Bavaria, 71.3 quarts; in England, 48 49; in Würtemberg, 47.3; in Saxony, 24.4; in Baden, 13.5; in Prussia, 13.11; in France, 9.7. The average consumption of alcoholic liquors is given by Reden at 13–14 quarts in Prussia, 11 in Hesse-Cassel, 6 in Saxony, 3.6 in Great Britain, 2 in Würtemberg, and 1.75 in France. The total consumption of coffee is, according to the same authority, 2,400,000,000 lbs. (average quantity per head in France 4.5 lbs., in the Zollverein 2.5, in Great Britain 1.1); of tea 70,000,000 lbs. (average per head 1.6 lb. in Great Britain; in the Zollverein not full ⅙ part of a pound). Of sugar the average consumption is: in Great Britain 17 lbs., in France 6.56, in the Zollverein 4.88 per head. Of the total consumption of tobacco (over 5,000,000 cwt.), nearly 80 per cent. is the share of Germany.—Christianity is almost exclusively the religion professed by the nations of Europe. The 3 principal denominations, viz., Roman Catholic, Protestant, and Greek, correspond nearly to the 3 principal races, Latin, German, and Slavic. The aggregate number of Roman Catholics is about 134,000,000. They constitute almost the entire population of Italy, Spain, Portugal, and

Russian Poland, 96 per cent. of the population of France, 76 per cent. of Austria, 71 per cent. of Bavaria, 52½ per cent. of all Germany, 82 per cent. of Ireland, 99½ per cent. of Belgium. Protestantism is the established faith in Great Britain and the Scandinavian kingdoms, and is professed by 96 per cent. of the population of Great Britain, 46½ per cent. of Germany, 57 per cent. of Holland, altogether by nearly 60,000,000 people. Greek Catholicism has 50,000,000 professors in Russia (83 per cent. of the total population), 10,000,000 in Turkey (66 per cent.), and about 6,000,000 in the Slavic provinces of Austria. Geographically Roman Catholicism is the dominant religion in the S. and S. W., Greek Catholicism in the E. and S. E., Protestantism in the N. and N. W. The number of Mohammedans is about 5,000,000 (3,500,000 in Turkey, the remainder in S. Russia), of Jews about 2,900,000, of Buddhists about 10,000 (Mongolian nomadic tribes in S. Russia), and of pagans about 1,000,000 (in the extreme N. of Russia).—Popular education, measured by the proportion of schools and pupils to the entire population, is more general in the countries inhabited by the Germanic race than among the Latin nations, and it holds the lowest place among the Slavic nations. In Saxony and the Thuringian principalities the proportion of pupils to the population is as 1 to 4; in Prussia, Sweden, and Norway, as 1 to 6; in Holland and Denmark, as 1 to 7; in England, as 1 to 8; in Austria and Scotland, as 1 to 10; in Belgium, as 1 to 10.5; in Ireland, as 1 to 12; in France, as 1 to 17; in Russia, as 1 to 93. Of the whole number of children under 15 years of age there remain without common-school education in Prussia 2.5 per cent., in Bavaria 20 per cent., in the German provinces of Austria 23 per cent., in Belgium 33 per cent., in France 44 per cent., in Spain 75 per cent., in Parma (Italy) 84 per cent., in Russia 90 per cent. In the higher branches of education Spain stands in the front rank. It has 8 universities with 8,400 students (1 to 1,630 of the whole population); next comes England (proportion of students to population as 1 to 1,795), then Sweden and Norway (1 to 1,800), Denmark (1 to 1,850), Portugal (1 to 2,624), Holland (1 to 3,230), Switzerland (1 to 3,285), Germany (1 to 3,419), France (1 to 3,440), Greece (1 to 3,610), Hungary (1 to 4,610), Russia (1 to 13,600). But in stating this proportion it is necessary to remark that the standard of professional education is very different in the countries named. What is termed a university in one country scarcely holds the rank of a college or an academy in another. Thus, Germany has only 22 universities proper, while it has hundreds of colleges (gymnasias), which, judged by the standard of the education they confer, would be entitled to the designation of universities in some other countries. Of educated men in Europe the Protestants have relatively the largest proportion; next come the Jews, then the Roman Catholics, and lastly the Greek Catho-

lics. Agricultural colleges and polytechnic institutes have been introduced at a comparatively recent date in Great Britain, Germany, Switzerland, France, Belgium, and Russia.—To judge of the moral status of European society by the criminal statistics is impossible, on account of the incompleteness of our information. Something may be learned in this respect from the proportion of illegitimate to legitimate births. This is lowest in some portions of Russia, where it is 3.19 per cent. of the total number of births; in the Two Sicilies it is 5 per cent., in Holland 5.24, in Sardinia 6.66, in Prussia 7.04, in France and Belgium 7.34, in the duchies of Mecklenburg 8.93 and 9.61 respectively, in Hanover 8.93, in Austria and Portugal 10, in Würtemberg 10.93, in the petty Saxon duchies 12.19, in the grand duchy of Hesse 13.43, in the kingdom of Saxony 13.88, in the grand duchy of Baden 13.88, in Bavaria 23.25. A much more unfavorable proportion obtains in the larger cities. Thus of the entire number of births in Genoa, 8.07 per cent. are illegitimate, in Berlin and Frankfort 14.23, in Turin 18.87, in St. Petersburg 22.22, in Munich 36.34, in Paris 52.63, in Vienna 62.5, in Strasbourg 66.66, in Lyons 71.42. But as a measure of public morality these proportions are insufficient, since the facilities for marrying are very different in different states. In some cases, especially in Mecklenburg and other petty German states, the obstacles to legal marriage are so great that numbers of people prefer to live together in a state of what would be perfectly legal wedlock in Scotland or America, but is only concubinage by the local laws of these states.—The present political systems of Europe are the product of nearly 20 centuries of strife and war among the different races inhabiting the continent. Though at certain periods of peace political philosophers and statesmen have endeavored to demonstrate the existence of a certain balance of power, which, by keeping in check the ambition of conquerors, should serve as a guarantee for the continuance of the actual state of things, there are in the whole history of Europe scarcely any two succeeding generations during which this idea has been realized. There has always been an almost continuous shifting of boundaries irrespective of nationalities, and there is not one of the great powers that does not hold in subjection portions of other nationalities. Thus Russia holds several German provinces, Finland, and part of the former Polish kingdom, not to mention countries the people of which belong to the Mongolian race. Prussia has some Polish provinces; Austria rules over Hungary and parts of Poland and Italy; France, Holland, and Denmark over portions of Germany (Alsace, Lorraine, Luxemburg, Schleswig-Holstein). Scarcely anywhere on the European continent is the form of government the spontaneous outgrowth of the popular will, and hence there is no remedy against abuse of anarchical power except revolutions. The fear of these has in many states compelled the rulers to subject their power to certain constitutional

restrictions, but, with the exception of Great Britain, Prussia, some of the smaller German states, Belgium, and Sardinia, constitutionalism is at best nominal. The relative rank of the different states is determined by their power to do mischief to each other, and the existence of most of the smaller states is simply owing to the jealousy of the greater ones. This is especially the case with the 8 republics which are tolerated in Europe (Switzerland, Ionian islands, San Marino, Andorra, and the free cities in Germany). Beside these, there are altogether 46 monarchical states, the rulers of which have different titles, such as emperor, king, grand duke, prince-elector, duke, prince, landgrave; but this difference in official titles does not imply any difference in sovereign power. These states are classified into those of the 1st, 2d, 3d, and 4th rank. The following are their names, area, and population, in 1859:

According to F. W. von Reden's statistical tables (1854), the yearly revenue of all the European states is \$1,324,832,394, of which sum \$595,534,191 belongs to the Germanic states, \$476,192,762 to the Latin or Romanic states, \$213,810,347 to Russia, \$32,413,857 to Turkey, and \$3,071,645 to Greece. The average of revenue is, in Great Britain \$9.37 per head, in France \$8.26, in Austria \$3.08, in Prussia \$4, in Switzerland \$2.51 (the lowest proportion in all Europe). The public debt of all European states amounted before 1850 to \$9,364,240,000, of which sum over \$6,000,000,000 was the public debt of the 5 great powers. But since then
